   Secure EL1 accesses to Secure ICC_SRE_EL1 trap to EL3.
   EL2 accesses to Non-secure ICC_SRE_EL1 and ICC_SRE_EL2 trap to EL3.
```
Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL3, unless these accesses are trapped to EL2 as a result of ICC_SRE_EL3.Enable == 0.

1 Secure EL1 accesses to Secure ICC_SRE_EL1 do not trap to EL3.
EL2 accesses to Non-secure ICC_SRE_EL1 and ICC_SRE_EL2 do not trap to EL3.
Non-secure EL1 accesses to ICC_SRE_EL1 do not trap to EL3.

If ICC_SRE_EL3.SRE is RAO/WI, an implementation is permitted to make the Enable bit RAO/WI.

If ICC_SRE_EL3.SRE is 0, the Enable bit behaves as 1 for all purposes other than reading the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

DIB, bit [2]
Disable IRQ bypass.
0 IRQ bypass enabled.
1 IRQ bypass disabled.

In systems that do not support IRQ bypass, this bit is RAO/WI.

When this register has an architecturally-defined reset value, this field resets to 0.

DFB, bit [1]
Disable FIQ bypass.
0 FIQ bypass enabled.
1 FIQ bypass disabled.

In systems that do not support FIQ bypass, this bit is RAO/WI.

When this register has an architecturally-defined reset value, this field resets to 0.

SRE, bit [0]
System Register Enable.
0 The memory-mapped interface must be used. Access at EL3 or below to any ICH_ register, or any EL1, EL2, or EL3 ICC_* register other than ICC_SRE_EL1, ICC_SRE_EL2, or ICC_SRE_EL3, results in an Undefined Instruction exception.
1 The System register interface to the ICH_* registers and the EL1, EL2, and EL3 ICC_* registers is enabled for EL3.

If software changes this bit from 1 to 0, the results are UNPREDICTABLE.

If an implementation supports only a System register interface to the GIC CPU interface, this bit is RAO/WI.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the ICC_SRE_EL3:

To access the ICC_SRE_EL3:

MRS <Xt>, ICC_SRE_EL3 ; Read ICC_SRE_EL3 into Xt
MSR ICC_SRE_EL3, <Xt> ; Write Xt to ICC_SRE_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1100</td>
<td>1100</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.8   Generic Interrupt Controller Virtual interface control System registers

See *About the Generic Interrupt Controller (GIC) System registers* on page D7-2292 for general information about the complete set of GIC registers, and about the subset of those registers that are described in this Manual.

This section describes the AArch64 GIC Virtual interface control System registers.
D7.8.1 ICH_AP0R<n>_EL2, Interrupt Controller Hyp Active Priorities Group 0 Registers, n = 0 - 3

The ICH_AP0R<n>_EL2 characteristics are:

Purpose

Provides information about Group 0 active priorities for EL2.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ICH_AP0R1_EL2 is only implemented in implementations that support 6 or more bits of priority.
ICH_AP0R2_EL2 and ICH_AP0R3_EL2 are only implemented in implementations that support 7 bits of priority. If an implementation that supports fewer bits of priority attempts to access these registers, it generates an Undefined Instruction exception.

If an implementation supports fewer than 5 bits of priority, then bits [31:2implemented bits] of ICH_AP0R0_EL2 are RAZ/WI, and bits [2implemented bits-1:0] correspond to valid priority levels.

Note

When fewer than 8 bits of priority are implemented, the priority corresponding to the lowest possible implemented priority can never be activated, so a corresponding active priority bit might not be implemented.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If ICC_SRE_EL2.SRE==0, EL2 accesses to this register are UNDEFINED.
If ICC_SRE_EL3.SRE==0, EL2 and EL3 accesses to this register are UNDEFINED.

Configurations

AArch64 System register ICH_AP0R<n>_EL2 is architecturally mapped to AArch32 System register ICH_AP0R<n>.

Attributes

ICH_AP0R<n>_EL2 is a 32-bit register.

Field descriptions

The ICH_AP0R<n>_EL2 bit assignments are:
P<\text{x}>, bit \([x]\), for \(x = 0\) to 31

Group 0 interrupt active priorities. Possible values of each bit are:
- 0 There is no Group 0 interrupt active at the priority corresponding to that bit.
- 1 There is a Group 0 interrupt active at the priority corresponding to that bit.

The correspondence between priorities and bits depends on the number of bits of priority that are implemented.

If 5 bits of priority are implemented (bits [7:3] of priority), then there are 32 priority groups, and the active state of these priorities are held in ICH_AP0R0_EL2 in the bits corresponding to Priority[7:3].

If 6 bits of priority are implemented (bits [7:2] of priority), then there are 64 priority groups, and:
- The active state of priorities 0 - 124 are held in ICH_AP0R0_EL2 in the bits corresponding to 0:Priority[6:2].
- The active state of priorities 128 - 252 are held in ICH_AP0R1_EL2 in the bits corresponding to 1:Priority[6:2].

If 7 bits of priority are implemented (bits [7:1] of priority), then there are 128 priority groups, and:
- The active state of priorities 0 - 62 are held in ICH_AP0R0_EL2 in the bits corresponding to 00:Priority[5:1].
- The active state of priorities 64 - 126 are held in ICH_AP0R1_EL2 in the bits corresponding to 01:Priority[5:1].
- The active state of priorities 128 - 190 are held in ICH_AP0R2_EL2 in the bits corresponding to 10:Priority[5:1].
- The active state of priorities 192 - 254 are held in ICH_AP0R3_EL2 in the bits corresponding to 11:Priority[5:1].

Note

Having the bit corresponding to a priority set to 1 in both ICH_AP0R<n> EL2 and ICH_AP1R<n> EL2 might cause the interrupt prioritization system for virtual interrupts to malfunction.

When this register has an architecturally-defined reset value, this field resets to 0.
Accessing the ICH_AP0R<n>_EL2:

To access the ICH_AP0R<n>_EL2:

MRS <Xt>, ICH_AP0R<n>_EL2 ; Read ICH_AP0R<n>_EL2 into Xt, where n is in the range 0 to 3
MSR ICH_AP0R<n>_EL2, <Xt> ; Write Xt to ICH_AP0R<n>_EL2, where n is in the range 0 to 3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1000</td>
<td>0:n&lt;1:0&gt;</td>
</tr>
</tbody>
</table>
D7.8.2 ICH_AP1R<n>_EL2, Interrupt Controller Hyp Active Priorities Group 1 Registers, n = 0 - 3

The ICH_AP1R<n>_EL2 characteristics are:

**Purpose**

Provides information about Group 1 active priorities for EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ICH_AP1R1_EL2 is only implemented in implementations that support 6 or more bits of priority. ICH_AP1R2_EL2 and ICH_AP1R3_EL2 are only implemented in implementations that support 7 bits of priority. If an implementation that supports fewer bits of priority attempts to access these registers, it generates an Undefined Instruction exception.

If an implementation supports fewer than 5 bits of priority, then bits [31:2implemented bits] of ICH_AP1R0_EL2 are RAZ/WI, and bits [2implemented bits-1:0] correspond to valid priority levels.

**Note**

When fewer than 8 bits of priority are implemented, the priority corresponding to the lowest possible implemented priority can never be activated, so a corresponding active priority bit might not be implemented.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.SRE==0, EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICH_AP1R<n>_EL2 is architecturally mapped to AArch32 System register ICH_AP1R<n>.

**Attributes**

ICH_AP1R<n>_EL2 is a 32-bit register.

**Field descriptions**

The ICH_AP1R<n>_EL2 bit assignments are:
P<x>, bit [x], for x = 0 to 31

Group 1 interrupt active priorities. Possible values of each bit are:

0 There is no Group 1 interrupt active at the priority corresponding to that bit.
1 There is a Group 1 interrupt active at the priority corresponding to that bit.

The correspondence between priorities and bits depends on the number of bits of priority that are implemented.

If 5 bits of priority are implemented (bits [7:3] of priority), then there are 32 priority groups, and the active state of these priorities are held in ICH_AP1R0_EL2 in the bits corresponding to Priority[7:3].

If 6 bits of priority are implemented (bits [7:2] of priority), then there are 64 priority groups, and:

- The active state of priorities 0 - 124 are held in ICH_AP1R0_EL2 in the bits corresponding to 0:Priority[6:2].
- The active state of priorities 128 - 252 are held in ICH_AP1R1_EL2 in the bits corresponding to 1:Priority[6:2].

If 7 bits of priority are implemented (bits [7:1] of priority), then there are 128 priority groups, and:

- The active state of priorities 0 - 62 are held in ICH_AP1R0_EL2 in the bits corresponding to 00:Priority[5:1].
- The active state of priorities 64 - 126 are held in ICH_AP1R1_EL2 in the bits corresponding to 01:Priority[5:1].
- The active state of priorities 128 - 190 are held in ICH_AP1R2_EL2 in the bits corresponding to 10:Priority[5:1].
- The active state of priorities 192 - 254 are held in ICH_AP1R3_EL2 in the bits corresponding to 11:Priority[5:1].

Note

Having the bit corresponding to a priority set to 1 in both ICH_AP0<n>_EL2 and ICH_AP1<n>_EL2 might cause the interrupt prioritization system for virtual interrupts to malfunction.

When this register has an architecturally-defined reset value, this field resets to 0.
Accessing the ICH_AP1R<\(n\)>_EL2:

To access the ICH_AP1R<\(n\)>_EL2:

- MRS <\(X_t\)>: ICH_AP1R<\(n\)>_EL2; Read ICH_AP1R<\(n\)>_EL2 into \(X_t\), where \(n\) is in the range 0 to 3
- MSR ICH_AP1R<\(n\)>_EL2, <\(X_t\)>; Write \(X_t\) to ICH_AP1R<\(n\)>_EL2, where \(n\) is in the range 0 to 3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1001</td>
<td>0:n&lt;1:0&gt;</td>
</tr>
</tbody>
</table>
### ICH_EISR_EL2, Interrupt Controller End of Interrupt Status Register

The ICH_EISR_EL2 characteristics are:

**Purpose**

Indicates which List registers have outstanding EOI maintenance interrupts.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.SRE==0, EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 read accesses to this register are UNDEFINED.

#### Configurations

AArch64 System register ICH_EISR_EL2 is architecturally mapped to AArch32 System register ICH_EISR.

#### Attributes

ICH_EISR_EL2 is a 32-bit register.

#### Field descriptions

The ICH_EISR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Status&lt;n&gt;, bit [n], for n = 0 to 15</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**Status<n>, bit [n], for n = 0 to 15**

EOI maintenance interrupt status bit for List register <n>:

- 0: List register <n>, ICH_LR<n>_EL2, does not have an EOI maintenance interrupt.
- 1: List register <n>, ICH_LR<n>_EL2, has an EOI maintenance interrupt that has not been handled.

For any ICH_LR<n>_EL2, the corresponding status bit is set to 1 if all of the following are true:

- ICH_LR<n>_EL2.State is 0b00.
- ICH_LR<n>_EL2.HW is 0.
- ICH_LR<n>_EL2.EOI (bit [41]) is 1, indicating that when the interrupt corresponding to that List register is deactivated, a maintenance interrupt is asserted.

When this register has an architecturally-defined reset value, this field resets to 0.
Accessing the ICH_EISR_EL2:

To access the ICH_EISR_EL2:

MRS <Xt>, ICH_EISR_EL2 ; Read ICH_EISR_EL2 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.8.4 ICH_ELRSR_EL2, Interrupt Controller Empty List Register Status Register

The ICH_ELRSR_EL2 characteristics are:

**Purpose**

Indicates which List registers contain valid interrupts.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.SRE==0, EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 read accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICH_ELRSR_EL2 is architecturally mapped to AArch32 System register ICH_ELRSR.

**Attributes**

ICH_ELRSR_EL2 is a 32-bit register.

**Field descriptions**

The ICH_ELRSR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Status&lt;n&gt;, bit [n], for n = 0 to 15</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**Status<n>, bit [n], for n = 0 to 15**

Status bit for List register <n>, ICH_LR<n>_EL2:

- 0 List register ICH_LR<n>_EL2, if implemented, contains a valid interrupt. Using this List register can result in overwriting a valid interrupt.
- 1 List register ICH_LR<n>_EL2 does not contain a valid interrupt. The List register is empty and can be used without overwriting a valid interrupt or losing an EOI maintenance interrupt.

For any List register <n>, the corresponding status bit is set to 1 if ICH_LR<n>_EL2.State is 0b00 and either ICH_LR<n>_EL2.HW is 1 or ICH_LR<n>_EL2.EOI (bit [41]) is 0.

**Accessing the ICH_ELRSR_EL2:**

To access the ICH_ELRSR_EL2:

MRS <Xt>, ICH_ELRSR_EL2 ; Read ICH_ELRSR_EL2 into Xt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.8.5 ICH_HCR_EL2, Interrupt Controller Hyp Control Register

The ICH_HCR_EL2 characteristics are:

Purpose

Controls the environment for Guest operating systems.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If ICC_SRE_EL2.SRE==0, EL2 accesses to this register are UNDEFINED.

If ICC_SRE_EL3.SRE==0, EL2 and EL3 accesses to this register are UNDEFINED.

Configurations

AArch64 System register ICH_HCR_EL2 is architecturally mapped to AArch32 System register ICH_HCR.

Attributes

ICH_HCR_EL2 is a 32-bit register.

Field descriptions

The ICH_HCR_EL2 bit assignments are:

EOIcount, bits [31:27]

Counts the number of EOIIs received that do not have a corresponding entry in the List registers. The virtual CPU interface increments this field automatically when a matching EOI is received.

EOIs that do not clear a bit in one of the Active Priorities registers, ICH_AP0R<n>_EL2 and ICH_AP1R<n>_EL2, do not cause an increment.

Although not possible under correct operation, if an EOI occurs when the value of this field is 31, this field wraps to 0.
The maintenance interrupt is asserted whenever this field is non-zero and the LRENPIE bit is set to 1.
When this register has an architecturally-defined reset value, this field resets to 0.

**Bits [26:14]**
Reserved, RES0.

**TSEI, bit [13]**
Trap all locally generated SEIs. This bit allows the hypervisor to intercept locally generated SEIs that would otherwise be taken at Non-secure EL1.

- 0 Locally generated SEIs do not cause a trap to EL2.
- 1 Locally generated SEIs trap to EL2.

If ICH_VTR_EL2.SEIS is 0, this bit is RES0.
When this register has an architecturally-defined reset value, this field resets to 0.

**TALL1, bit [12]**
Trap all Non-secure EL1 accesses to ICC_* System registers for Group 1 interrupts to EL2.

- 0 Non-Secure EL1 accesses to ICC_* registers for Group 1 interrupts proceed as normal.
- 1 Any Non-secure EL1 accesses to ICC_* registers for Group 1 interrupts trap to EL2.

When this register has an architecturally-defined reset value, this field resets to 0.

**TALL0, bit [11]**
Trap all Non-secure EL1 accesses to ICC_* System registers for Group 0 interrupts to EL2.

- 0 Non-Secure EL1 accesses to ICC_* registers for Group 0 interrupts proceed as normal.
- 1 Any Non-secure EL1 accesses to ICC_* registers for Group 0 interrupts trap to EL2.

When this register has an architecturally-defined reset value, this field resets to 0.

**TC, bit [10]**
Trap all Non-secure EL1 accesses to System registers that are common to Group 0 and Group 1 to EL2.

- 0 Non-secure EL1 accesses to common registers proceed as normal.
- 1 Any Non-secure EL1 accesses to common registers trap to EL2.

This affects accesses to ICC_SGI0R_EL1, ICC_SGI1R_EL1, ICC_ASGI1R_EL1, ICC_CTLR_EL1, ICC_DIR_EL1, ICC_PMR_EL1, and ICC_RPR_EL1.
When this register has an architecturally-defined reset value, this field resets to 0.

**Bits [9:8]**
Reserved, RES0.

**VGrp1DIE, bit [7]**
VM Group 1 Disabled Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

- 0 Maintenance interrupt disabled.
- 1 Maintenance interrupt signaled when ICH_VMCR_EL2.VENG1 is 0.

When this register has an architecturally-defined reset value, this field resets to 0.

**VGrp1EIE, bit [6]**
VM Group 1 Enabled Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

- 0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled when ICH_VMCR_EL2.VENG1 is 1.
When this register has an architecturally-defined reset value, this field resets to 0.

VGrp0DIE, bit [5]
VM Group 0 Disabled Interrupt Enable. Enables the signaling of a maintenance interrupt while
signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is
disabled:
0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled when ICH_VMCR_EL2.VENG0 is 0.
When this register has an architecturally-defined reset value, this field resets to 0.

VGrp0EIE, bit [4]
VM Group 0 Enabled Interrupt Enable. Enables the signaling of a maintenance interrupt while
signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is
enabled:
0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled when ICH_VMCR_EL2.VENG0 is 1.
When this register has an architecturally-defined reset value, this field resets to 0.

NPIE, bit [3]
No Pending Interrupt Enable. Enables the signaling of a maintenance interrupt while no pending
interrupts are present in the List registers:
0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled while the List registers contain no interrupts in the
pending state.
When this register has an architecturally-defined reset value, this field resets to 0.

LRENPIE, bit [2]
List Register Entry Not Present Interrupt Enable. Enables the signaling of a maintenance interrupt
while the virtual CPU interface does not have a corresponding valid List register entry for an EOI
request:
0 Maintenance interrupt disabled.
1 Maintenance interrupt is asserted while the EOIconf field is not 0.
When this register has an architecturally-defined reset value, this field resets to 0.

UIE, bit [1]
Underflow Interrupt Enable. Enables the signaling of a maintenance interrupt when the List
registers are empty, or hold only one valid entry:
0 Maintenance interrupt disabled.
1 Maintenance interrupt is asserted if none, or only one, of the List register entries is
marked as a valid interrupt.
When this register has an architecturally-defined reset value, this field resets to 0.

En, bit [0]
Enable. Global enable bit for the virtual CPU interface:
0 Virtual CPU interface operation disabled.
1 Virtual CPU interface operation enabled.
When this field is set to 0:
• The virtual CPU interface does not signal any maintenance interrupts.
• The virtual CPU interface does not signal any virtual interrupts.
• A read of GICV_IAR or GICV_AIAR returns a spurious interrupt ID.
When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the ICH_HCR_EL2:**

To access the ICH_HCR_EL2:

MRS <Xt>, ICH_HCR_EL2 ; Read ICH_HCR_EL2 into Xt
MSR ICH_HCR_EL2, <Xt> ; Write Xt to ICH_HCR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.8.6 ICH_LR<\text{n}>_EL2, Interrupt Controller List Registers, n = 0 - 15

The ICH_LR<\text{n}>_EL2 characteristics are:

**Purpose**

Provides interrupt context information for the virtual CPU interface.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.SRE==0, EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICH_LR<\text{n}>_EL2[31:0] is architecturally mapped to AArch32 System register ICH_LR<\text{n}>.

AArch64 System register ICH_LR<\text{n}>_EL2[63:32] is architecturally mapped to AArch32 System register ICH_LRC<\text{n}>.

**Attributes**

ICH_LR<\text{n}>_EL2 is a 64-bit register.

**Field descriptions**

The ICH_LR<\text{n}>_EL2 bit assignments are:

**State, bits [63:62]**

The state of the interrupt:

- 00: Inactive
- 01: Pending
- 10: Active
- 11: Pending and active.

The GIC updates these state bits as virtual interrupts proceed through the interrupt life cycle. Entries in the inactive state are ignored, except for the purpose of generating virtual maintenance interrupts. For hardware interrupts, the pending and active state is held in the physical Distributor rather than the virtual CPU interface. A hypervisor must only use the pending and active state for software originated interrupts, which are typically associated with virtual devices, or SGIs.

When this register has an architecturally-defined reset value, this field resets to 0.
**HW, bit [61]**

Indicates whether this virtual interrupt maps directly to a hardware interrupt, meaning that it corresponds to a physical interrupt. Deactivation of the virtual interrupt also causes the deactivation of the physical interrupt with the ID that the pINTID field indicates.

0 The interrupt is triggered entirely by software. No notification is sent to the Distributor when the virtual interrupt is deactivated.

1 The interrupt maps directly to a hardware interrupt. A deactivate interrupt request is sent to the Distributor when the virtual interrupt is deactivated, using the pINTID field from this register to indicate the physical interrupt ID.

If ICH_VMCR_EL2.VEOIM is 0, this request corresponds to a write to ICC_EOIR0_EL1 or ICC_EOIR1_EL1. Otherwise, it corresponds to a write to ICC_DIR_EL1.

When this register has an architecturally-defined reset value, this field resets to 0.

**Group, bit [60]**

Indicates the group for this virtual interrupt.

0 This is a Group 0 virtual interrupt. ICH_VMCR_EL2.VFIQEn determines whether it is signaled as a virtual IRQ or as a virtual FIQ, and ICH_VMCR_EL2.VENG0 enables signaling of this interrupt to the virtual machine.

1 This is a Group 1 virtual interrupt, signaled as a virtual IRQ. ICH_VMCR_EL2.VENG1 enables the signaling of this interrupt to the virtual machine.

If ICH_VMCR_EL2.VCBPR is 0, then ICC_BPR1_EL1 determines if a pending Group 1 interrupt has sufficient priority to preempt current execution. Otherwise, ICC_BPR0_EL1 determines preemption.

When this register has an architecturally-defined reset value, this field resets to 0.

**Bits [59:56]**

Reserved, RES0.

**Priority, bits [55:48]**

The priority of this interrupt.

It is IMPLEMENTATION DEFINED how many bits of priority are implemented, though at least five bits must be implemented. Unimplemented bits are RES0 and start from bit [48] up to bit [50]. The number of implemented bits can be discovered from ICH_VTR_EL2.PRIbits.

When this register has an architecturally-defined reset value, this field resets to 0.

**Bits [47:42]**

Reserved, RES0.

**pINTID, bits [41:32]**

Physical interrupt ID, for hardware interrupts.

When the HW bit is 0 (there is no corresponding physical interrupt), this field has the following meaning:

**Bit [41]** EOI. If this bit is 1, then when the interrupt identified by vINTID is deactivated, a maintenance interrupt is asserted.

**Bits [40:32]** Reserved, RES0.

When the HW bit is 1 (there is a corresponding physical interrupt):

- This field indicates the physical interrupt ID that the hypervisor forwards to the Distributor. This field is only required to implement enough bits to hold a valid value for the ID configuration. Any unused higher order bits are RES0.
- If the value of pINTID is 0-15 or 1020-1023, behavior is UNPREDICTABLE. If the value of pINTID is 16-31, this field applies to the PPI associated with this same physical PE ID as the virtual CPU interface requesting the deactivation.
A hardware physical identifier is only required in List Registers for interrupts that require deactivation. This means only 10 bits of Physical ID are required, regardless of the number specified by ICC_CTLR_EL1.IDbits.

When this register has an architecturally-defined reset value, this field resets to 0.

**vINTID, bits [31:0]**

Virtual ID of the interrupt.

Software must ensure there is only a single valid entry for a given vINTID.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH_VTR_EL2.IDbits.

When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the ICH_LR<n>_EL2:**

To access the ICH_LR<n>_EL2:

MRS <Xt>, ICH_LR<n>_EL2 ; Read ICH_LR<n>_EL2 into Xt, where n is in the range 0 to 15
MSR ICH_LR<n>_EL2, <Xt> ; Write Xt to ICH_LR<n>_EL2, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>110:n&lt;3&gt;</td>
<td>n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>
### D7.8.7 ICH_MISR_EL2, Interrupt Controller Maintenance Interrupt State Register

The ICH_MISR_EL2 characteristics are:

#### Purpose
Indicates which maintenance interrupts are asserted.

#### Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

#### Traps and Enables
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:
- If ICC_SRE_EL2.SRE==0, EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 read accesses to this register are UNDEFINED.

#### Configurations
AArch64 System register ICH_MISR_EL2 is architecturally mapped to AArch32 System register ICH_MISR.

#### Attributes
ICH_MISR_EL2 is a 32-bit register.

#### Field descriptions
The ICH_MISR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>U</td>
</tr>
<tr>
<td>5</td>
<td>VGrp1E</td>
</tr>
<tr>
<td>4</td>
<td>VGrp1D</td>
</tr>
<tr>
<td>3</td>
<td>VGrp0E</td>
</tr>
<tr>
<td>2</td>
<td>LRENP</td>
</tr>
<tr>
<td>1</td>
<td>EOI</td>
</tr>
</tbody>
</table>

#### Bits [31:8]
Reserved, RES0.

#### VGrp1D, bit [7]
VM Group 1 Disabled.
- 0: VM Group 1 Disabled maintenance interrupt not asserted.
- 1: VM Group 1 Disabled maintenance interrupt asserted.

This maintenance interrupt is asserted when ICH_HCR_EL2.VGrp1DIE is 1 and ICH_VMCR_EL2.VMGrp1En is 0.

When this register has an architecturally-defined reset value, this field resets to 0.
VGrp1E, bit [6]
VM Group 1 Enabled.
0 VM Group 1 Enabled maintenance interrupt not asserted.
1 VM Group 1 Enabled maintenance interrupt asserted.
This maintenance interrupt is asserted when ICH_HCR_EL2.VGrp1EIE is 1 and ICH_VMCR_EL2.VMGrp1En is 1.
When this register has an architecturally-defined reset value, this field resets to 0.

VGrp0D, bit [5]
VM Group 0 Disabled.
0 VM Group 0 Disabled maintenance interrupt not asserted.
1 VM Group 0 Disabled maintenance interrupt asserted.
This maintenance interrupt is asserted when ICH_HCR_EL2.VGrp0DIE is 1 and ICH_VMCR_EL2.VMGrp0En is 0.
When this register has an architecturally-defined reset value, this field resets to 0.

VGrp0E, bit [4]
VM Group 0 Enabled.
0 VM Group 0 Enabled maintenance interrupt not asserted.
1 VM Group 0 Enabled maintenance interrupt asserted.
This maintenance interrupt is asserted when ICH_HCR_EL2.VGrp0EIE is 1 and ICH_VMCR_EL2.VMGrp0En is 1.
When this register has an architecturally-defined reset value, this field resets to 0.

NP, bit [3]
No Pending.
0 No Pending maintenance interrupt not asserted.
1 No Pending maintenance interrupt asserted.
This maintenance interrupt is asserted when ICH_HCR_EL2.NPIE is 1 and no List register is in pending state.
When this register has an architecturally-defined reset value, this field resets to 0.

LRENP, bit [2]
List Register Entry Not Present.
0 List Register Entry Not Present maintenance interrupt not asserted.
1 List Register Entry Not Present maintenance interrupt asserted.
This maintenance interrupt is asserted when ICH_HCR_EL2.LRENPIE is 1 and ICH_HCR_EL2.EOLcount is non-zero.
When this register has an architecturally-defined reset value, this field resets to 0.

U, bit [1]
Underflow.
0 Underflow maintenance interrupt not asserted.
1 Underflow maintenance interrupt asserted.
This maintenance interrupt is asserted when ICH_HCR_EL2.UIE is 1 and zero or one of the List register entries are marked as a valid interrupt, that is, if the corresponding ICH_LR<n>_EL2.State bits do not equal 0x0.
When this register has an architecturally-defined reset value, this field resets to 0.
EOI, bit [0]

End Of Interrupt.

0  End Of Interrupt maintenance interrupt not asserted.
1  End Of Interrupt maintenance interrupt asserted.

This maintenance interrupt is asserted when at least one bit in ICH_EISR_EL2 is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the ICH_MISR_EL2:

To access the ICH_MISR_EL2:

MRS <Xt>, ICH_MISR_EL2 ; Read ICH_MISR_EL2 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.8.8 ICH_VMCR_EL2, Interrupt Controller Virtual Machine Control Register

The ICH_VMCR_EL2 characteristics are:

**Purpose**

Enables the hypervisor to save and restore the virtual machine view of the GIC state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

When EL2 is using System register access, EL1 using either System register or memory-mapped access must be supported.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.SRE==0, EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICH_VMCR_EL2 is architecturally mapped to AArch32 System register ICH_VMCR.

**Attributes**

ICH_VMCR_EL2 is a 32-bit register.

**Field descriptions**

The ICH_VMCR_EL2 bit assignments are:

31 24 23 21 20 18 17 10 9 8 5 4 3 2 1 0

VPMR VBPR0 VBPR1 RES0 RES0

VPMR, bits [31:24]

Virtual Priority Mask. The priority mask level for the virtual CPU interface. If the priority of a pending virtual interrupt is higher than the value indicated by this field, the interface signals the virtual interrupt to the PE.

Visible to the virtual PE as ICC_PMR_EL1.Priority.
VBPR0, bits [23:21]
Virtual Binary Point Register, Group 0. Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field determines Group 0 interrupt preemption, and also determines Group 1 interrupt preemption if ICH_VMCR_EL2.VCBPR == 1.
Visible to the virtual PE as ICC_BPR0_EL1.Binary_Point.

VBPR1, bits [20:18]
Virtual Binary Point Register, Group 1. Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field determines Group 1 interrupt preemption if ICH_VMCR_EL2.VCBPR == 0.
Visible to the virtual PE as ICC_BPR1_EL1.Binary_Point.

Bits [17:10]
Reserved, RES0.

VEOIM, bit [9]
Virtual EOImode. Possible values of this bit are:
0 A write of an INTID to ICC_EOIR0_EL1 or ICC_EOIR1_EL1 drops the priority of the interrupt with that INTID, and also deactivates that interrupt.
1 A write of an INTID to ICC_EOIR0_EL1 or ICC_EOIR1_EL1 only drops the priority of the interrupt with that INTID. Software must write to ICC_DIR_EL1 to deactivate the interrupt.
Visible to the virtual PE as ICC_CTLR_EL1.EOImode.

Bits [8:5]
Reserved, RES0.

VCBPR, bit [4]
Virtual Common Binary Point Register. Possible values of this bit are:
0 ICC_BPR1_EL1 determines the preemption group for Non-secure Group 1 interrupts.
1 ICC_BPR0_EL1 determines the preemption group for Non-secure Group 1 interrupts. Non-secure accesses to GICC_BPR and ICC_BPR1_EL1 access the state of ICC_BPR0_EL1.
Visible to the virtual PE as ICC_CTLR_EL1.CBPR.

VFIQEn, bit [3]
Virtual FIQ enable. Possible values of this bit are:
0 Group 0 virtual interrupts are presented as virtual IRQs.
1 Group 0 virtual interrupts are presented as virtual FIQs.
Visible to the virtual PE as GICV_CTLR.FIQEn.

VAckCtl, bit [2]
Virtual AckCtl. Possible values of this bit are:
0 If the highest priority pending interrupt is Group 1, a read of GICV_IAR or GICV_HPPIR returns an interrupt ID of 1022.
1 If the highest priority pending interrupt is Group 1, a read of GICV_IAR or GICV_HPPIR returns the interrupt ID of the corresponding interrupt.
Visible to the virtual PE as GICV_CTLR.AckCtl.
This field is supported for backwards compatibility with GICv2. ARM deprecates the use of this field.
VNG1, bit [1]

Virtual Group 1 interrupt enable. Possible values of this bit are:

0  Group 1 virtual interrupts are disabled.
1  Group 1 virtual interrupts are enabled.

Visible to the virtual PE as IICC_IGRPEN1_EL1.Enable.

VNG0, bit [0]

Virtual Group 0 interrupt enable. Possible values of this bit are:

0  Group 0 virtual interrupts are disabled.
1  Group 0 virtual interrupts are enabled.

Visible to the virtual PE as IICC_IGRPEN0_EL1.Enable.

Accessing the ICH_VMCR_EL2:

To access the ICH_VMCR_EL2:

MRS <Xt>, ICH_VMCR_EL2 ; Read ICH_VMCR_EL2 into Xt
MSR ICH_VMCR_EL2, <Xt> ; Write Xt to ICH_VMCR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.8.9 ICH_VTR_EL2, Interrupt Controller VGIC Type Register

The ICH_VTR_EL2 characteristics are:

**Purpose**

Describes the number of implemented virtual priority bits and List registers.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.SRE==0, EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL2 and EL3 read accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICH_VTR_EL2 is architecturally mapped to AArch32 System register ICH_VTR.

**Attributes**

ICH_VTR_EL2 is a 32-bit register.

**Field descriptions**

The ICH_VTR_EL2 bit assignments are:

```
0 1 | 2 3 | 4 5 | 6 7 | 8 9 | 10 11 | 12 13 | 14 15 | 16 17 | 18 19 | 20 21 | 22 23 | 24 25 | 26 27 | 28 29 | 30 31
-----------------------------
PRIbits | PREbits | IDbits | RES0 | ListRegs
```

**PRIbits, bits [31:29]**

The number of virtual priority bits implemented, minus one.

An implementation must implement at least 32 levels of virtual priority (5 priority bits).

**PREbits, bits [28:26]**

The number of virtual preemption bits implemented, minus one.

An implementation must implement at least 32 levels of virtual preemption priority (5 preemption bits).

**IDbits, bits [25:23]**

The number of virtual interrupt identifier bits supported:

- 000: 16 bits.
- 001: 24 bits.

All other values are reserved.
SEIS, bit [22]

SEI Support. Indicates whether the virtual CPU interface supports generation of SEIs:

0  The virtual CPU interface logic does not support generation of SEIs.
1  The virtual CPU interface logic supports generation of SEIs.

A3V, bit [21]

Affinity 3 Valid. Possible values are:

0  The virtual CPU interface logic only supports zero values of Affinity 3 in SGI generation System registers.
1  The virtual CPU interface logic supports non-zero values of Affinity 3 in SGI generation System registers.

nV4, bit [20]

GICv4 direct injection of virtual interrupts not supported. Possible values are:

0  The CPU interface logic supports direct injection of virtual interrupts.
1  The CPU interface logic does not support direct injection of virtual interrupts.

Bits [19:5]

Reserved, RES0.

ListRegs, bits [4:0]

The number of implemented List registers, minus one. For example, a value of 0b01111 indicates that the maximum of 16 List registers are implemented.

Accessing the ICH_VTR_EL2:

To access the ICH_VTR_EL2:

MRS <Xt>, ICH_VTR_EL2 ; Read ICH_VTR_EL2 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>001</td>
</tr>

</table>
Part E

The AArch32 Application Level Architecture
Chapter E1
The AArch32 Application Level Programmers’ Model

This chapter gives an Application level description of the programmers’ model for software executing in AArch32 state. This means it describes execution in EL0 when EL0 is using AArch32. It contains the following sections:

• About the Application level programmers’ model on page E1-2378.
• Additional information about the programmers’ model in AArch32 state on page E1-2379.
• Advanced SIMD and floating-point instructions on page E1-2393.
• Conceptual coprocessor support on page E1-2422.
• Exceptions on page E1-2423.
E1.1 About the Application level programmers’ model

This chapter contains the programmers’ model information required for the development of applications that will execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers’ model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different Exception levels that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers’ model is the programmers’ model for software executing at EL0. For more information see ARMv8 architectural concepts on page A1-35.

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This has the following effects:

• It means that the operating system can allocate system resources to an application in a unique or shared manner.

• It provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

When included in an implementation:

• EL3 provides two Security states, Secure and Non-secure. Secure state provides additional hardware features that support the development of secure applications.

• EL2 provides virtualization of operation in Non-secure state.

However, application level software is generally unaware of its Security state, and of any virtualization. For more information, see The ARMv8-A security model on page G1-3815 and The effect of implementing EL2 on the Exception model on page G1-3818.

Note

• When an implementation includes EL3, application and operating system software normally executes in Non-secure state.

• EL2, that provides the virtualization features, is implemented only in Non-secure state.

• Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at EL1 as privileged execution.

• In this manual, the terms CONstrained UNPREDICTABLE, IMPLEMENTATION DEFINED, OPTIONAL, RES0, RES1, UNDEFINED, UNKNOWN, and UNPREDICTABLE have special meanings, as defined in the Glossary. In body text, these terms are shown in SMALL CAPS, for example IMPLEMENTATION DEFINED.
E1.2 Additional information about the programmers’ model in AArch32 state

The following sections give more information about the Application level programmers’ model in AArch32 state:

- Instruction sets, arithmetic operations, and register files.
- Core data types and arithmetic in AArch32 state.
- The general-purpose registers, and the PC, in AArch32 state on page E1-2384.
- Process state, PSTATE on page E1-2387.

E1.2.1 Instruction sets, arithmetic operations, and register files

The A32 and T32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that are comprised of the AArch32 general-purpose registers and the PC. As described in The general-purpose registers, and the PC, in AArch32 state on page E1-2384, these registers include the special registers SP and LR. Core data types and arithmetic in AArch32 state gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:

- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in The SIMD and floating-point register file on page E1-2393. Advanced SIMD and floating-point instructions on page E1-2393 gives more information about these instructions.

E1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

- **Byte** 8 bits
- **Halfword** 16 bits
- **Word** 32 bits
- **Doubleword** 64 bits.

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers,
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

---

**Note**

For information about the atomicity of memory accesses see Atomicity in the ARM architecture on page E2-2440.

---

When any of the data types is described as *unsigned*, the N-bit data value represents a non-negative integer in the range 0 to \(2^{N-1}\), using normal binary format.

When any of these types is described as *signed*, the N-bit data value represents an integer in the range \(-2^{(N-1)}\) to \(+2^{(N-1)}-1\), using two's complement format.
The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

--- Note ---
These SIMD instructions operate on values held in the general-purpose registers, and must not be confused with the Advanced SIMD instructions that operate on a separate register file that provides registers of up 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

**Integer arithmetic**

The instruction set provides a wide range of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode described in Appendix J9 ARM Pseudocode Definition defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in Operators and built-in functions on page J9-5767.
- By use of pseudocode helper functions defined in the main text. See Appendix J10 Pseudocode Index.
- By a sequence of the form:
  1. Use of the SInt(), UInt(), and Int() built-in functions defined in Converting bitstrings to integers on page J9-5769 to convert the bitstring contents of the instruction operands to the unbounded integers that they represent as two's complement or unsigned integers.
  2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to calculate other such integers.
  3. Use of either the bitstring extraction operator defined in Bitstring extraction on page J9-5768 or of the saturation helper functions described in Pseudocode description of saturation on page E1-2383 to convert an unbounded integer result into a bitstring result that can be written to a register.

**Shift and rotate operations**

The following types of shift and rotate operations are used in instructions:

**Logical Shift Left**

(LSL) moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

**Logical Shift Right**

(LSR) moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

**Arithmetic Shift Right**

(ASR) moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

**Rotate Right**

(ROR) moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

**Rotate Right with Extend**

(RRX) moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.
Pseudocode description of shift and rotate operations

These shift and rotate operations are supported in pseudocode by the following functions:

// LSL_C()
// ========
<bits(N), bit) LSL_C(bits(N) x, integer shift)
assert shift > 0;
extended_x = x : Zeros(shift);
result = extended_x<N-1:0>;
carry_out = extended_x<N>;
return (result, carry_out);

// LSL()
// ======
<bits(N) LSL(bits(N) x, integer shift)
assert shift >= 0;
if shift == 0 then
  result = x;
else
  (result, -) = LSL_C(x, shift);
return result;

// LSR_C()
// ========
<bits(N), bit) LSR_C(bits(N) x, integer shift)
assert shift > 0;
extended_x = ZeroExtend(x, shift+N);
result = extended_x<shift+N-1:shift>;
carry_out = extended_x<shift-1>;
return (result, carry_out);

// LSR()
// ======
<bits(N) LSR(bits(N) x, integer shift)
assert shift >= 0;
if shift == 0 then
  result = x;
else
  (result, -) = LSR_C(x, shift);
return result;

// ASR_C()
// ========
<bits(N), bit) ASR_C(bits(N) x, integer shift)
assert shift > 0;
extended_x = SignExtend(x, shift+N);
result = extended_x<shift+N-1:shift>;
carry_out = extended_x<shift-1>;
return (result, carry_out);

// ASR()
// ======
<bits(N) ASR(bits(N) x, integer shift)
assert shift >= 0;
if shift == 0 then
  result = x;
else
  (result, -) = ASR_C(x, shift);
return result;

// ROR_C()
// ======
(bits(N), bit) ROR_C(bits(N) x, integer shift)
assert shift != 0;
m = shift MOD N;
result = LSR(x,m) OR LSL(x,N-m);
carry_out = result<N-1>
return (result, carry_out);

// ROR()
// ======
bits(N) ROR(bits(N) x, integer shift)
assert shift >= 0;
if shift == 0 then
  result = x;
else
  (result, -) = ROR_C(x, shift);
return result;

// RRX_C()
// ======
(bits(N), bit) RRX_C(bits(N) x, bit carry_in)
result = carry_in : x<N-1:1>
carry_out = x<0>
return (result, carry_out);

// RRX()
// ======
bits(N) RRX(bits(N) x, bit carry_in)
(result, -) = RRX_C(x, carry_in);
return result;

Pseudocode description of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise. For the definition of these operations, see Addition and subtraction on page J9-5770.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode the AddWithCarry() function provides an addition with a carry input and a set of output Condition flags including carry output and overflow:

// AddWithCarry()
// ==============
// Integer addition with carry input, returning result and NZCV flags
(bits(N), bits(4)) AddWithCarry(bits(N) x, bits(N) y, bit carry_in)
integer unsigned_sum = UInt(x) + UInt(y) + UInt(carry_in);
integer signed_sum = SInt(x) + SInt(y) + UInt(carry_in);
bits(N) result = unsigned_sum<N-1:0>; // same value as signed_sum<N-1:0>
bit n = result<N-1>
bit z = if IsZero(result) then '1' else '0';
bit c = if UInt(result) == unsigned_sum then '0' else '1';
bit v = if SInt(result) == signed_sum then '0' else '1';
return (result, n:z:c:v);

An important property of the AddWithCarry() function is that if:
(result, nzcv) = AddWithCarry(x, NOT(y), carry_in)
Then:

- If \( \text{carry}_\text{in} = '1' \), then \( \text{result} = x - y \) with:
  - \( \text{nzcv}_\text{<0>} = '1' \) if signed overflow occurred during the subtraction.
  - \( \text{nzcv}_\text{<1>} = '1' \) if unsigned borrow did not occur during the subtraction, that is, if \( x \geq y \).

- If \( \text{carry}_\text{in} = '0' \), then \( \text{result} = x - y - 1 \) with:
  - \( \text{nzcv}_\text{<0>} = '1' \) if signed overflow occurred during the subtraction.
  - \( \text{nzcv}_\text{<1>} = '1' \) if unsigned borrow did not occur during the subtraction, that is, if \( x \geq y \).

Taken together, this means that the \( \text{carry}_\text{in} \) and \( \text{nzcv}_\text{<1>} \) output in \text{AddWithCarry()} \) calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

**Pseudocode description of saturation**

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned \( N \)-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo \( 2^N \). This is supported in pseudocode by:

- The \text{SignedSatQ()} and \text{UnsignedSatQ()} functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.

- The \text{SignedSat()} and \text{UnsignedSat()} functions when only the saturated result is required.

```plaintext
// SignedSatQ()
// ============
<bits(N), boolean) SignedSatQ(integer i, integer N)
if i > 2^(N-1) - 1 then
  result = 2^(N-1) - 1;  saturated = TRUE;
elseif i < -(2^(N-1)) then
  result = -(2^(N-1));  saturated = TRUE;
else
  result = i;  saturated = FALSE;
return (result<N-1:0>, saturated);

// UnsignedSatQ()
// ==============
<bits(N), boolean) UnsignedSatQ(integer i, integer N)
if i > 2^N - 1 then
  result = 2^N - 1;  saturated = TRUE;
elseif i < 0 then
  result = 0;  saturated = TRUE;
else
  result = i;  saturated = FALSE;
return (result<N-1:0>, saturated);

// SignedSat()
// ===========
<bits(N) SignedSat(integer i, integer N)
  (result, -) = SignedSatQ(i, N);
  return result;

// UnsignedSat()
// =============
<bits(N) UnsignedSat(integer i, integer N)
  (result, -) = UnsignedSatQ(i, N);
  return result;

SatQ(i, N, unsigned) returns either \text{UnsignedSatQ}(i, N) or \text{SignedSatQ}(i, N) depending on the value of its third argument, and \text{Sat}(i, N, unsigned) returns either \text{UnsignedSat}(i, N) or \text{SignedSat}(i, N) depending on the value of its third argument:
```
E1.2 Additional information about the programmers’ model in AArch32 state

E1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
  - R13 is usually identified as SP.
  - R14 is usually identified as LR.
- The PC (program counter), that can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

SP, the stack pointer

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP, and for most T32 instructions ARM deprecates using SP as a general-purpose register. The only T32 instructions for which the use of SP is not deprecated are those designed to use SP as a stack pointer.

The A32 instruction set provides more general access to the SP, and it can be used as a general-purpose register. However, ARM deprecates the use of SP for any purpose other than as a stack pointer.

Note

- Using SP for any purpose other than as a stack pointer is likely to break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.
- Before ARMv8, for most T32 instructions, using SP as a general-purpose register was UNPREDICTABLE. In ARMv8, most of these uses of SP behave predictably, but are deprecated by ARM. The instruction descriptions give more information.

Software can refer to SP as R13.

LR, the link register

The link register is a special register that can hold return link information. Some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

PC, the program counter

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, ARM deprecates the use of PC for any purpose other than as the program counter. See Writing to the PC on page E1-2385 for more information.
Software can refer to PC as R15.

See AArch32 general-purpose registers, and the PC on page G1-3825 for the system level view of these registers.

**Note**
In general, ARM strongly recommends using the names SP, LR and PC instead of R13, R14 and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to registers R8 to R15, rather than to registers R8 to R12, the SP, LR and PC. These two descriptions of the group of registers have exactly the same meaning.

**Writing to the PC**

In the A32 and T32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
  - Encoding T2 of ADD, ADDS (register) on page F7-2647.
  - Encoding T1 of MOV, MOVS (register) on page F7-2876.
  
  The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.

- The B, BL, CBNZ, CBZ, CHKA, HB, HBL, HBP, TB8, and TBB# instructions remain in the same instruction set state and branch to the value written to the PC.
  
  The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.

- The BLX (immediate) instruction switches between A32 and T32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.

- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
  - BLX (register), BX, and BXO.
  - LDR instructions with <Rt> equal to the PC.
  - POP and all forms of LDM except LDM (exception return), when the register list includes the PC.
  - In A32 state only, ADC, ADD, ADR, AND, ASR (immediate), BIC, EOR, LSL (immediate), LSR (immediate), MOV, MVN, ORR, ROR (immediate), RX, RS8, RSC, 8C, and SUB instructions with <Rd> equal to the PC and without flag-setting specified.

  For details of how an interworking address specifies the new instruction set state and instruction address, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

**Note**

The register-shifted register instructions, that are available only in the A32 instruction set and are summarized in Data-processing (register-shifted register) on page F4-2567, are UNPREDICTABLE if they attempt to write to the PC.

- Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see Exception return to an Exception level using AArch32 on page G1-3860.

- Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.
Pseudocode description of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the \( R[] \) function are:
- Reading or writing \( R0-R12, SP, \) and \( LR \), using \( n = 0-12, 13, \) and \( 14 \) respectively.
- Reading the PC, using \( n = 15 \).

This function has prototypes:

```plaintext
array bits(64) _R[0..30];
```

Pseudocode description of general-purpose register and PC operations on page G1-3826 explains the full operation of this function.

Descriptions of A32 store instructions that store the PC value use the \( \text{PCStoreValue()} \) pseudocode function to specify the PC value stored by the instruction:

```plaintext
// PCStoreValue()
// =============

bits(32) PCStoreValue()
  // This function returns the PC value. On architecture versions before ARMv7, it
  // is permitted to instead return PC+4, provided it does so consistently. It is
  // used only to describe A32 instructions, so it returns the address of the current
  // instruction plus 8 (normally) or 12 (when the alternative is permitted).
  return PC;
```

Writing an address to the PC causes either a simple branch to that address or an interworking branch that also selects the instruction set to execute after the branch. A simple branch is performed by the \( \text{BranchWritePC()} \) function:

```plaintext
// BranchWritePC()
// ==============

BranchWritePC(bits(32) address)
  if CurrentInstrSet() == InstrSet_A32 then
    address<1:0> = '00';
  else
    address<0> = '0';
  BranchTo(address, BranchType_UNKNOWN);
```

An interworking branch is performed by the \( \text{BXWritePC()} \) function:

```plaintext
// BXWritePC()
// ===========

BXWritePC(bits(32) address)
  if address<0> == '1' then
    SelectInstrSet(InstrSet_T32);
    address<0> = '0';
  else
    SelectInstrSet(InstrSet_A32);
    // For branches to an unaligned PC counter in A32 state, the processor takes the branch
    // and does one of:
    // * Forces the address to be aligned
    // * Leaves the PC unaligned, meaning the target generates a PC Alignment fault.
    if address<1> == '1' & ConstrainUnpredictableBool() then
      address<1> = '0';
    BranchTo(address, BranchType_UNKNOWN);
```
The LoadWritePC() and ALUWritePC() functions are used for two cases where the behavior was systematically modified between architecture versions:

```c
// LoadWritePC()
// =============
LoadWritePC(bits(32) address)
BXWritePC(address);

// ALUWritePC()
// ============
ALUWritePC(bits(32) address)
if CurrentInstrSet() == InstrSet_A32 then
  BXWritePC(address);
else
  BranchWritePC(address);
```

### E1.2.4 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

The following PSTATE information is accessible at EL0:

The condition flags

Flag-setting instructions set these. They are:

- **N** Negative condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
  - 1 if the result is negative.
  - 0 if the result is positive or zero.

- **Z** Zero condition flag. Set to:
  - 1 if the result of the instruction is zero.
  - 0 otherwise.

A result of zero often indicates an equal result from a comparison.

- **C** Carry condition flag. Set to:
  - 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
  - 0 otherwise.

- **V** Overflow condition flag. Set to:
  - 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
  - 0 otherwise.

Conditional instructions test the N, Z, C, and V condition flags, combining them with the *condition code* for the instruction, to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see *Conditional execution on page F2-2517.*

The overflow or saturation flag

- **Q** Some instructions can set this. For those instructions that can, the PE:
  - Sets it to 1 if the instruction indicates overflow or saturation.
  - Leaves it unchanged otherwise.

For more information, see *Pseudocode description of saturation on page E1-2383.*
The greater than or equal flags

GE[3:0]  The instructions described in *Parallel addition and subtraction instructions on page F1-2488* update these to indicate the results from individual bytes or halfwords of the operation. These flags can control a later SEL instruction. For more information, see SEL on page F7-3021.

PSTATE also contains *Execution State controls*. There is no direct access to these from application level instructions, but they can be changed by side-effects of application level instructions. They are:

**Instruction set state**

**J, T**  The current instruction set state, as shown in Table E1-1. In ARMv8, the J bit is RES0, see the Note in this section.

<table>
<thead>
<tr>
<th>J</th>
<th>T</th>
<th>Instruction set state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>T32</td>
</tr>
</tbody>
</table>

A32  The PE is executing the A32 instruction set, summarized in both:

- Chapter F4 A32 Base Instruction Set Encoding.
- Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings.

T32  The PE is executing the T32 instruction set, summarized in both:

- Chapter F3 T32 Base Instruction Set Encoding.
- Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings.

---

**Note**

**Encoding with J==1 before ARMv8, Jazelle and T32EE states**

In previous versions of the ARM architecture, the encoding {1, 0} selected Jazelle state, and encoding {1, 1} selected T32EE state. ARMv8 does not support either of these states, and these are encodings for unimplemented instruction set states, see *Unimplemented instruction sets on page G1-3839*. ARMv8 AArch32 state requires a Trivial Jazelle implementation, see *Trivial implementation of the Jazelle extension on page G1-3839.*

**The IT block state**

**IT[7:0]**  The If-Then controls for the T32 IT instruction, that applies to the *IT block* of instructions that immediately follows the IT instruction. See IT on page F7-2750 for a description of the IT instruction and its associated IT block.

PSTATE.IT divides into two subfields:

**IT[7:5]**  Holds the *base condition* for the current IT block. The base condition is the top three bits of the condition code specified by the <firstcond> field of the IT instruction.

**IT[4:0]**  Encodes:

- The size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is implied by the position of the least significant 1 in this field, as shown in Table E1-2 on page E1-2389.
- For each instruction in the IT block, the least significant bit of the condition code. This is encoded where Table E1-2 on page E1-2389 shows N<index>. 
Changing the least significant bit of a condition code from 0 to 1 has the effect of inverting the condition code.

Both subfields are all zeros when no IT block is active.

When an IT instruction is executed, PSTATE.IT is set according to the <firstcond> field of the instruction and the Then and Else (T and E) parameters in the instruction. See IT on page F7-2750.

When permitted, an instruction in an IT block is conditional, see Conditional instructions on page F1-2479 and Conditional execution on page F2-2517. The condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, PSTATE.IT advances to the next line of Table E1-2. A few instructions, for example BKPT, cannot be conditional and therefore are always executed, ignoring the current value of PSTATE.IT.

For details of what happens if an instruction in an IT block takes an exception, see Overview of exception entry on page G1-3848.

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in PSTATE.IT advancing to normal execution.

Table E1-2 shows the effect of the If-Then controls. N<index> represents an instruction in the IT block. For example, N1 is the first instruction in the block, and N2 is the second instruction in the block.

### Table E1-2 Effect of IT Execution state controls

<table>
<thead>
<tr>
<th>IT bits&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>[7:5] [4] [3] [2] [1] [0]</td>
<td>Entry point for an IT block with four instructions</td>
</tr>
<tr>
<td>cond_base N1 N2 N3 N4 1</td>
<td></td>
</tr>
<tr>
<td>cond_base N1 N2 N3 1 0 0</td>
<td></td>
</tr>
<tr>
<td>cond_base N1 N2 1 0 0 0</td>
<td></td>
</tr>
<tr>
<td>cond_base N1 1 0 0 0 0</td>
<td></td>
</tr>
<tr>
<td>000 0 0 0 0 0</td>
<td>Normal execution, not in an IT block</td>
</tr>
</tbody>
</table>

<sup>a</sup> Combinations of the IT bits not shown in this table are reserved.

On a branch or an exception return, if PSTATE.IT is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is UNPREDICTABLE.

PSTATE.IT affects instruction execution only in T32 state. In A32 state, PSTATE.IT must be 0b00000000, otherwise the behavior is UNPREDICTABLE.

**Endianness mapping**

E

For data accesses, controls the endianness:

0  Little-endian.

1  Big-endian.

If an implementation does not provide:

• Big-endian support for data accesses, this bit is RES0.

• Little-endian support for data accesses, this bit is RES1.

Instruction fetches are always little-endian, and ignore PSTATE.E.
Accessing PSTATE fields at EL0

The following sections describe which PSTATE fields can be directly accessed at EL0, and how they can be accessed:

- The Application Program Status Register, APSR.
- The SETEND instruction.

The Application Program Status Register, APSR

At EL0, some PSTATE fields can be accessed using the Special-purpose Application Program Status Register (APSR). The APSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.

The APSR bit assignments are:

N, Z, C, V , bits [31:28]  
The PSTATE condition flags.

Q, bit [27]  
The PSTATE overflow or saturation flag.

Bits[26:24]  
Reserved, RAZ/SBZP. Software can use MSR instructions that write the top byte of the APSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

Bits[23:20, 15:0]  
Reserved bits that are allocated to system features, or are available for future expansion. Unprivileged execution ignores writes to fields that are accessible only at EL1 or higher. However, application level software that writes to the APSR must treat reserved bits as Do-Not-Modify (DNM) bits. For more information about the reserved bits, see The Current Program Status Register, CPSR on page G1-3834.

GE[3:0], bits [19:16]  
The PSTATE greater than or equal flags.

The other PSTATE fields cannot be accessed by using the APSR.

The system level alias for the APSR is the CPSR. The CPSR is a superset of the APSR. See The Current Program Status Register, CPSR on page G1-3834.

Writes to the PSTATE fields have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the APSR write. This means they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

- SETEND BE  
  Sets PSTATE.E to 1, for big-endian operation.
- SETEND LE  
  Sets PSTATE.E to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see SETEND on page F7-3023. ARM deprecates use of the SETEND instruction.
Pseudocode description of PSTATE Execution State fields

The following pseudocode functions return the current instruction set and select a new instruction set:

// CurrentInstrSet()
// ================

InstrSet CurrentInstrSet()
    if UsingAArch32() then
        result = if PSTATE.T == '0' then InstrSet_A32 else InstrSet_T32;
        // PSTATE.J is RES0. Implementation of T32EE or Jazelle state not permitted.
    else
        result = InstrSet_A64;
    return result;

// SelectInstrSet()
// ================

SelectInstrSet(InstrSet iset)
    assert CurrentInstrSet() IN {InstrSet_A32, InstrSet_T32};
    assert iset IN {InstrSet_A32, InstrSet_T32};
    PSTATE.T = if iset == InstrSet_A32 then '0' else '1';
    return;

PSTATE.IT advances after normal execution of an IT block instruction. This is described by the ITAdvance() pseudocode function:

// AArch32.ITAdvance()
// ===============

AArch32.ITAdvance()
    if PSTATE.IT<2:0> == '000' then
        PSTATE.IT = '00000000';
    else
        PSTATE.IT<4:0> = LSL(PSTATE.IT<4:0>, 1);
    return;

The following functions test whether the current instruction is in an IT block, and whether it is the last instruction in an IT block.

// InITBlock()
// ===========

boolean InITBlock()
    if CurrentInstrSet() == InstrSet_T32 then
        return PSTATE.IT<3:0> != '0000';
    else
        return FALSE;

// LastInITBlock()
// ===============

boolean LastInITBlock()
    return (PSTATE.IT<3:0> == '1000');

The BigEndian() pseudocode function tests whether big-endian data memory accesses are currently selected.

// BigEndian()
// ===========

boolean BigEndian()
    boolean bigend;
E1 The AArch32 Application Level Programmers’ Model
E1.2 Additional information about the programmers’ model in AArch32 state

```c
if UsingAArch32() then
    bigend = (PSTATE.E != '0');
elsif PSTATE.EL == EL0 then
    bigend = (SCTRL_EL1.EE != '0');
else
    bigend = (SCTRL[].EE != '0');
return bigend;
```

E1.2.5 Jazelle support

ARMv8 requires AArch32 state to include a trivial implementation of the Jazelle extension, as described in *Trivial implementation of the Jazelle extension* on page G1-3839.
E1.3 Advanced SIMD and floating-point instructions

In general, ARMv8 requires implementation of Advanced SIMD and floating-point instructions in the T32 and A32 instruction sets, but see Implications of not including Advanced SIMD and floating-point support on page E1-2401.

The Advanced SIMD instructions perform packed Single Instruction Multiple Data (SIMD) operations, either integer or single-precision floating-point. The floating-point instructions perform single-precision or double-precision scalar floating-point operations.

These instructions permit floating-point exceptions, such as overflow or division by zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. ARMv8 also optionally supports the trapping of floating-point exceptions, see Trapping of floating-point exceptions on page E1-2397. For more information about floating-point exceptions see Floating-point exceptions on page E1-2398.

The floating-point and Advanced SIMD instructions also provide conversion functions in both directions between half-precision floating-point and single-precision floating-point.

Some Advanced SIMD instructions support polynomial arithmetic over \{0, 1\}, as described in Polynomial arithmetic over \{0, 1\} on page A1-47.

For system level information about the Advanced SIMD and Floating-point implementation see Advanced SIMD and floating-point support on page G1-3914.

The following sections give more information about the Advanced SIMD and floating-point instructions:

- The SIMD and floating-point register file.
- Data types supported by the Advanced SIMD implementation on page E1-2396.
- Advanced SIMD and floating-point system registers on page E1-2397.
- Trapping of floating-point exceptions on page E1-2397.
- Floating-point data types and arithmetic on page E1-2397.
- Floating-point exceptions on page E1-2398.
- Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2401.
- Implications of not including Advanced SIMD and floating-point support on page E1-2401.
- Pseudocode description of floating-point operations on page E1-2401.

E1.3.1 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, that comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. Figure E1-1 on page E1-2394 shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, Q0-Q15.
- Thirty-two 64-bit doubleword registers, D0-D31.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in D0 and D1 and a 128-bit vector in Q1.
Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, that can be viewed as:

- Thirty-two 64-bit doubleword registers, D0-D31. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, S0-S31. Only half of the set is accessible in this view.

The two views can be used simultaneously.

SIMD and Floating-point register file mapping onto registers

Figure E1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

The mapping between the registers is as follows:

- $S_{2n}$ maps to the least significant half of $D_n$.
- $S_{2n+1}$ maps to the most significant half of $D_n$.
- $D_{2n}$ maps to the least significant half of $Q_n$.
- $D_{2n+1}$ maps to the most significant half of $Q_n$.

For example, software can access the least significant half of the elements of a vector in $Q_6$ by referring to $D_{12}$, and the most significant half of the elements by referring to $D_{13}$.
Pseudocode description of the SIMD and Floating-point register file

The array \_V defines the SIMD and floating-point register file:

```c
array bits(128) _V[0..31];
```

**Note**

AArch32 only uses the first 16 of the registers, V0 - V15.

The following functions provide the S0-S31, D0-D31, and Q0-Q15 views of the registers:

```c
array bits(64) _Dclone[0..31];
```

// S[] - non-assignment form
// ================

```c
bits(32) S[integer n]
assert n >= 0 && n <= 31;
base = (n MOD 4) * 32;
return _V[n DIV 4]<base+31:base>;
```

// S[] - assignment form
// =====================

```c
S[integer n] = bits(32) value
assert n >= 0 && n <= 31;
base = (n MOD 4) * 32;
_V[n DIV 4]<base+31:base> = value;
return;
```

// D[] - non-assignment form
// =========================

```c
bits(64) D[integer n]
assert n >= 0 && n <= 31;
base = (n MOD 2) * 64;
return _V[n DIV 2]<base+63:base>;
```

// D[] - assignment form
// =====================

```c
D[integer n] = bits(64) value
assert n >= 0 && n <= 31;
base = (n MOD 2) * 64;
_V[n DIV 2]<base+63:base> = value;
return;
```

The Din[] function returns a Doubleword register from the _Dclone[] copy of the SIMD and Floating-point register file, and the Qin[] function returns a Quadword register from that register file.

**Note**

The CheckAdvancedSIMDEnabled() function copies the D[] register file to _Dclone[], see Pseudocode description of enabling SIMD and floating-point functionality on page G1-3950.

// Din[] - non-assignment form
// ===========================

```c
bits(64) Din[integer n]
assert n >= 0 && n <= 31;
return _Dclone[n];
```

// Qin[] - non-assignment form
// ===========================
E1.3 Advanced SIMD and floating-point instructions

E1.3.2 Data types supported by the Advanced SIMD implementation

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. *Vector formats in AArch32 state* on page A1-40 describes these formats.

Advanced SIMD vectors

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. In *Vector formats in AArch32 state* on page A1-40, Figure A1-3 on page A1-42 shows the Advanced SIMD vector formats.

Pseudocode description of Advanced SIMD vectors

The pseudocode function `Elem[]` accesses the element of a specified index and size in a vector:

```
// Elem[] - non-assignment form
// ====================================
bits(size) Elem<bits(N) vector, integer e, integer size]
    assert e >= 0 && (e+1)*size <= N;
    return vector<e*size+size-1 : e*size>;

// Elem[] - non-assignment form
// ====================================
bits(size) Elem<bits(N) vector, integer e]
    return Elem[vector, e, size];

// Elem[] - assignment form
// ========================
Elem<bits(N) &vector, integer e, integer size] = bits(size) value
    assert e >= 0 && (e+1)*size <= N;
    vector<(e+1)*size-1:e*size> = value;
    return;

// Elem[] - assignment form
// ========================
Elem<bits(N) &vector, integer e] = bits(size) value
    Elem[vector, e, size] = value;
    return;
```
E1.3.3 Advanced SIMD and floating-point system registers

The Advanced SIMD and floating-point instructions have a shared register space for system registers. Only one register in this space is accessible at the Application level, see FPSCR, Floating-Point Status and Control Register on page G6-4385.

Writes to the FPSCR can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the FPSCR write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See Advanced SIMD and floating-point system registers on page G1-3916 for the system level view of the registers.

These registers can be described as the SIMD and floating-point system registers.

E1.3.4 Trapping of floating-point exceptions

It is IMPLEMENTATION DEFINED whether the floating-point implementation supports the trapping of floating-point exceptions:

- If it does, the FPSCR.\{IDE, IXE, UFE, OFE, DZE, IOE\} bits enable the exception traps.
- Otherwise, the FPSCR trap bits are RES0.

Trapped exception handling never causes the corresponding cumulative exception bit of the FPSCR to be set to 1. If this behavior is desired, the trap handler routine must use a read, modify, write sequence on the FPSCR to set the cumulative exception bit.

E1.3.5 Floating-point data types and arithmetic

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage only, by supporting conversions between single-precision and half-precision data types.

ARM standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the restrictions described in Floating-point and Advanced SIMD support on page A1-48, including supporting only the input and output values described in ARM standard floating-point input and output values on page A1-50.

The AArch32 Advanced SIMD instructions support only single-precision ARM standard floating-point arithmetic.

Note

The floating-point instructions require support code to be installed in the system if trapped floating-point exception handling is required. See Floating-point exception traps on page G1-3917.

The following sections describe the Advanced SIMD and floating-point formats:

The following sections describe features of Advanced SIMD and floating-point processing:

E1.3.6 Floating-point exceptions

ARM Advanced SIMD and floating-point instructions record the following floating-point exceptions in the FPSCR cumulative bits, unless the floating-point exception is trapped and generates an exception:

**FPSCR.IOC** Invalid Operation. The bit is set to 1 if the result of an operation has no mathematical value or cannot be represented. Cases include, for example:
- $\infty \times 0$.
- $\infty + (-\infty)$.

These tests are made after flush-to-zero processing. For example, if flush-to-zero mode is selected, multiplying a denormalized number and an infinity is treated as $(0 \times \infty)$, and causes an Invalid Operation floating-point exception.

IOC is also set on any floating-point operation with one or more signaling NaNs as operands, except for negation and absolute value, as described in Floating-point negation and absolute value on page E1-2403.

**FPSCR.DZC** Division by Zero. The bit is set to 1 if a divide operation has a zero divisor and a dividend that is not zero, an infinity or a NaN. These tests are made after flush-to-zero processing, so if flush-to-zero processing is selected, a denormalized dividend is treated as zero and prevents Division by Zero from occurring, and a denormalized divisor is treated as zero and causes Division by Zero to occur if the dividend is a normalized number.

For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be $+1.0$. This means that a zero or denormalized operand to these functions sets the DZC bit.

**FPSCR.OFC** Overflow. The bit is set to 1 if the absolute value of the result of an operation, produced after rounding, is greater than the maximum positive normalized number for the destination precision.

**FPSCR.UFC** Underflow. The bit is set to 1 if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, and the rounded result is inexact.

The criteria for the Underflow exception to occur are different in Flush-to-zero mode. For details, see Flush-to-zero on page A1-51.

**FPSCR.IXC** Inexact. The bit is set to 1 if the result of an operation is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

The criteria for the Inexact exception to occur are different in Flush-to-zero mode. For details, see Flush-to-zero on page A1-51.

**FPSCR.IDC** Input Denormal. The bit is set to 1 if a denormalized input operand is replaced in the computation by a zero, as described in Flush-to-zero on page A1-51.

For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

For floating-point instructions when floating-point exception trapping is supported:

- These exceptions can be trapped, by setting trap enable bits in the FPSCR, see Trapping of floating-point exceptions on page E1-2397 and Floating-point exception traps on page G1-3917, and:
  - When a trap is not enabled the corresponding floating-point exception updates the corresponding FPSCR cumulative bit does not generate an exception.
  - When a trap is enabled the corresponding floating-point exception does not update the FPSCR, but generates an exception. In this case, bits in the FPEXC indicate which floating-point exceptions have occurred.
• The definition of the Underflow exception is different in the trapped and cumulative exception cases. In the trapped case the definition is:
  — The trapped Underflow exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.

• As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in *Combinations of floating-point exceptions*.

• For Invalid Operation exceptions, for details of which quiet NaN is produced as the default result see *NaN handling and the Default NaN* on page A1-52.

• For Overflow exceptions, the sign bit of the default result is determined normally for the overflowing operation.

• For Division by Zero exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.

Table E1-3 shows the results of untrapped floating-point exceptions. That table uses the following abbreviations:

MaxNorm The maximum normalized number of the destination precision.
RM Round towards Minus Infinity mode, as defined in the IEEE 754 standard.
RN Round to Nearest mode, as defined in the IEEE 754 standard.
RP Round towards Plus Infinity mode, as defined in the IEEE 754 standard.
RZ Round towards Zero mode, as defined in the IEEE 754 standard.

For more information about the IEEE 754 descriptions of the rounding modes see *Floating-point standards, and terminology* on page A1-50.

**Combinations of floating-point exceptions**

The following pseudocode functions perform *floating-point operations*:

- FixedToFP()
- FPAAdd()
- FPCCompare()
- FPCCompareEQ()
- FPCCompareGE()
- FPCCompareGT()
- FPDiv()
- FPMax()
- FPMin()
- FPMul()
- FPMulAdd()
- FPRecipEstimate()
- FPRecipStep()
- FPRSqrtEstimate()
All of these operations can generate floating-point exceptions.

--- Note ---

FPAbs() and FPNeg() are not classified as floating-point operations because:
- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:

More than one exception can occur on the same operation. The only combinations of exceptions that can occur are:
- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other exceptions.

When none of the exceptions caused by an operation are trapped, any exception that occurs causes the associated cumulative bit in the FPSCR to be set.

When one or more exceptions caused by an operation are trapped, the behavior of the instruction depends on the priority of the exceptions. The Inexact exception is treated as lowest priority, and Input Denormal as highest priority:

- If the higher priority exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether any information about the lower priority exception is provided.

  --- Note ---

  Information about the lower priority exception might be provided in:
  - The FPEXC, if the exception generated by the trap is taken to an Exception level that is using AArch32.
  - The ESR_ELx.ISS field, if the exception generated by the trap is taken to an Exception level that is using AArch64.

  However, information might be provided in another IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

  ---

  Apart from this, the lower priority exception is ignored in this case.

- If the higher priority exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, an exception on one operation is treated as higher priority than an exception on another operation if the occurrence of the second exception depends on the result of the first operation. Otherwise, it is UNPREDICTABLE which exception is treated as higher priority.

For example, a VMLA.F32 instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any exception on the multiplication. The same applies to Invalid Operation exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is UNPREDICTABLE which of an Input Denormal exception on the addition and an exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal exception does not depend on the result of the multiplication. The same applies to an Invalid Operation exception on the addition caused by the addend being a signaling NaN.
E1.3.7 Controls of Advanced SIMD operation that do not apply to floating-point operation

ARMv7 permitted implementation of either, both, or neither of the Advanced SIMD and floating-point additions to the base instruction set, and provided some controls that applied to the Advanced SIMD functionality but not to the floating-point functionality. In ARMv8, Advanced SIMD functionality cannot be separated from floating-point functionality, but in AArch32 state these controls function as they did in ARMv7. This means they apply only to the following instructions and instruction encodings:

- All instructions with encodings defined in Advanced SIMD data-processing instructions on page F5-2597.
- All instructions with encodings defined in Advanced SIMD element or structure load/store instructions on page F5-2613.
- The form of the VDUP instruction described in VDUP (general-purpose register) on page F8-3432.
- The byte and halfword forms of the VMOV instructions described in each of:
  - VMOV (general-purpose register to scalar) on page F8-3546.
  - VMOV (scalar to general-purpose register) on page F8-3550.

The controls of this functionality are:

- The CPACR.ASEDIS bit.
- The HCPTR.TASE bit.

E1.3.8 Implications of not including Advanced SIMD and floating-point support

In general, ARMv8 requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the CPACR.{cp10, cp11} fields is RES0.
- The CPACR.ASEDIS bit is RES0.
- Each of the HCPTR.{TASE, TCP10, TCP11} fields is RES1.
- Each of the NSACR.{NSASEDIS, cp10, cp11} fields is RES0.
- The FPEXC register is UNDEFINED.

E1.3.9 Pseudocode description of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the ARMv8 architecture:

- Generation of specific floating-point values on page E1-2402.
- Floating-point negation and absolute value on page E1-2403.
- Floating-point value unpacking on page E1-2403.
- Floating-point exception and NaN handling on page E1-2404.
- Floating-point rounding on page E1-2406.
- Selection of ARM standard floating-point arithmetic on page E1-2408.
- Floating-point comparisons on page E1-2408.
- Floating-point maximum and minimum on page E1-2409.
- Floating-point addition and subtraction on page E1-2410.
• Floating-point multiplication and division on page E1-2411.
• Floating-point fused multiply-add on page E1-2412.
• Floating-point reciprocal estimate and step on page E1-2413.
• Floating-point square root on page E1-2415.
• Floating-point reciprocal square root estimate and step on page E1-2416.
• Floating-point conversions on page E1-2419.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The sign argument is '0' for the positive version and '1' for the negative version.

// FPInfinity()
// ============
bits(N) FPInfinity(bit sign)
assert N IN {16,32,64};
constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
constant integer F = N - E - 1;
exp  = Ones(E);
frac = Zeros(F);
return sign : exp : frac;

// FPMaxNormal()
// =============
bits(N) FPMaxNormal(bit sign)
assert N IN {16,32,64};
constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
constant integer F = N - E - 1;
exp  = Ones(E-1):'0';
frac = Ones(F);
return sign : exp : frac;

// FPZero()
// ========
bits(N) FPZero(bit sign)
assert N IN {16,32,64};
constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
constant integer F = N - E - 1;
exp  = Zeros(E);
frac = Zeros(F);
return sign : exp : frac;

// FPTwo()
// ========
bits(N) FPTwo(bit sign)
assert N IN {32,64};
constant integer E = (if N == 32 then 8 else 11);
constant integer F = N - E - 1;
exp  = '1':Zeros(E-1);
frac = Zeros(F);
return sign : exp : frac;

// FPThree()
// ==========
bits(N) FPThree(bit sign)
assert N IN {32,64};
constant integer E = (if N == 32 then 8 else 11);
constant integer F = N - E - 1;
exp  = '1':Zeros(E-1);
frac = '1':Zeros(F-1);
return sign : exp : frac;

// FPDefaultNaN()
// =============

bits(N) FPDefaultNaN()
assert N IN \{16,32,64\};
constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
constant integer F = N - E - 1;
sign = '0';
exp = Ones(E);
frac = '1':Zeros(F-1);
return sign : exp : frac;

Floating-point negation and absolute value

The floating-point negation and absolute value operations only affect the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

// FPNeg()
// =======

bits(N) FPNeg(bits(N) op)
assert N IN \{32,64\};
return NOT(op<N-1>) : op<N-2:0>;

// FPAbs()
// ======

bits(N) FPAbs(bits(N) op)
assert N IN \{32,64\};
return '0' : op<N-2:0>;

Floating-point value unpacking

The FPUnpack() function determines the type and numerical value of a floating-point number. It also does flush-to-zero processing on input operands.

classification FPType {FPType_Nonzero, FPType_Zero, FPType_Infinity, FPType_QNaN, FPType_SNaN};

// FPUnpack()
// =========
//
// Unpack a floating-point number into its type, sign bit and the real number
// that it represents. The real number result has the correct sign for numbers
// and infinities, is very large in magnitude for infinities, and is 0.0 for
// NaNs. (These values are chosen to simplify the description of comparisons
// and conversions.)
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

(FPType, bit, real) FPUnpack(bits(N) fpval, FPCRType fpcr)
assert N IN \{16,32,64\};

if N == 16 then
    sign   = fpval<15>;
    exp16  = fpval<14:10>;
    frac16 = fpval<9:0>;
    if IsZero(exp16) then
        // Produce zero if value is zero
        if IsZero(frac16) then
            type = FPType_Zero;  value = 0.0;
        else
            type = FPType_Nonzero;  value = 2.0^-14 * (UInt(frac16) * 2.0^-10);
elsif IsOnes(exp16) && fpcr.AHP == '0' then  // Infinity or NaN in IEEE format
    if IsZero(frac16) then
        type = FPType_Infinity; value = 2.0^1000000;
    else
        type = if frac16<9> == '1' then FPType_QNaN else FPType_SNaN;
        value = 0.0;
    else
        type = FPType_Nonzero; value = 2.0^(UInt(exp16)-15) * (1.0 + UInt(frac16) * 2.0^-10);
    endif
elsif N == 32 then
    sign   = fpval<31>;
    exp32  = fpval<30:23>;
    frac32 = fpval<22:0>;
    if IsZero(exp32) then
        // Produce zero if value is zero or flush-to-zero is selected.
        if IsZero(frac32) || fpcr.FZ == '1' then
            type = FPType_Zero; value = 0.0;
        else
            FPProcessException(FPExc_InputDenorm, fpcr);
            type = FPType_Nonzero; value = 2.0^-126 * (UInt(frac32) * 2.0^-23);
        endif
    elsif IsOnes(exp32) then
        if IsZero(frac32) then
            type = FPType_Infinity; value = 2.0^1000000;
        else
            type = if frac32<22> == '1' then FPType_QNaN else FPType_SNaN;
            value = 0.0;
        else
            type = FPType_Nonzero; value = 2.0^(UInt(exp32)-127) * (1.0 + UInt(frac32) * 2.0^-23);
        endif
    else // N == 64
    sign   = fpval<63>;
    exp64  = fpval<62:52>;
    frac64 = fpval<51:0>;
    if IsZero(exp64) then
        // Produce zero if value is zero or flush-to-zero is selected.
        if IsZero(frac64) || fpcr.FZ == '1' then
            type = FPType_Zero; value = 0.0;
        else
            FPProcessException(FPExc_InputDenorm, fpcr);
            type = FPType_Nonzero; value = 2.0^-1022 * (UInt(frac64) * 2.0^-52);
        endif
    elsif IsOnes(exp64) then
        if IsZero(frac64) then
            type = FPType_Infinity; value = 2.0^1000000;
        else
            type = if frac64<51> == '1' then FPType_QNaN else FPType_SNaN;
            value = 0.0;
        else
            type = FPType_Nonzero; value = 2.0^(UInt(exp64)-1023) * (1.0 + UInt(frac64) * 2.0^-52);
        endif
    endif
if sign == '1' then value = -value;
return (type, sign, value);

**Floating-point exception and NaN handling**

The FPProcessException() procedure checks whether a floating-point exception is trapped, and handles it accordingly:

```
enumeration FPExc       {FPExc_InvalidOp, FPExc_DivideByZero, FPExc_Overflow,
                        FPExc_Underflow, FPExc_Inexact, FPExc_InputDenorm};

// FPProcessException()
// ====================
```

The 'fpcr' argument supplies FPCR control bits. Status information is updated directly in the FPSR where appropriate.

FPProcessException(FPExc exception, FPCRType fpcr)
// Determine the cumulative exception bit number
case exception of
    when FPExc_InvalidOp    cumul = 0;
    when FPExc_DivideByZero cumul = 1;
    when FPExc_Overflow     cumul = 2;
    when FPExc_Underflow    cumul = 3;
    when FPExc_Inexact      cumul = 4;
    when FPExc_InputDenorm  cumul = 7;
enable = cumul + 8;
if fpcr<enable> == '1' then
    // Trapping of the exception enabled.
    // It is IMPLEMENTATION DEFINED whether the enable bit may be set at all, and
    // if so then how exceptions may be accumulated before calling FPTrapException()
    IMPLEMENTATION_DEFINED "floating-point trap handling";
elsif UsingAArch32() then
    // Set the cumulative exception bit
    FPSCR<cumul> = '1';
else
    // Set the cumulative exception bit
    FPSR<cumul> = '1';
return;

The FPProcessNaN() function processes a NaN operand, producing the correct result value and generating an Invalid Operation exception if necessary:

// FPProcessNaN()
// ==============

bits(N) FPProcessNaN(FPType type, bits(N) op, FPCRType fpcr)
assert N IN {32,64};
assert type IN {FPType_QNaN, FPType_SNaN};
topfrac = if N == 32 then 22 else 51;
result = op;
if type == FPType_SNaN then
    result<topfrac> = '1';
FPProcessException(FPExc_InvalidOp, fpcr);
if fpcr.DN == '1' then  // DefaultNaN requested
    result = FPDefaultNaN();
return result;

The FPProcessNaNs() function performs the standard NaN processing for a two-operand operation:

// FPProcessNaNs()
// ===============
// The boolean part of the return value says whether a NaN has been found and
// processed. The bits(N) part is only relevant if it has and supplies the
// result of the operation.
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

(boolean, bits(N)) FPProcessNaNs(FPType type1, FPType type2,
    bits(N) op1, bits(N) op2,
    FPCRType fpcr)
assert N IN {32,64};
if type1 == FPType_SNaN then
    done = TRUE;  result = FPProcessNaN(type1, op1, fpcr);
elsif type2 == FPType_SNaN then
    done = TRUE;  result = FPProcessNaN(type2, op2, fpcr);
elsif type1 == FPType_QNaN then
    done = TRUE;  result = FPProcessNaN(type1, op1, fpcr);
elsif type2 == FPType_QNaN then
done = TRUE; result = FPProcessNaN(type2, op2, fpcr);
else
  done = FALSE; result = Zeros(); // 'Don't care' result
return (done, result);

The FPProcessNaNs3() function performs the standard NaN processing for a three-operand operation:

// FPProcessNaNs3()
// ================
// The boolean part of the return value says whether a NaN has been found and
// processed. The bits(N) part is only relevant if it has and supplies the
// result of the operation.
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

(boolean, bits(N)) FPProcessNaNs3(FPType type1, FPType type2, FPType type3,
  bits(N) op1, bits(N) op2, bits(N) op3,
  FPCRType fpcr)
assert N IN {32,64};
if type1 == FPType_SNaN then
  done = TRUE; result = FPProcessNaN(type1, op1, fpcr);
elsif type2 == FPType_SNaN then
  done = TRUE; result = FPProcessNaN(type2, op2, fpcr);
elsif type3 == FPType_SNaN then
  done = TRUE; result = FPProcessNaN(type3, op3, fpcr);
elsif type1 == FPType_QNaN then
  done = TRUE; result = FPProcessNaN(type1, op1, fpcr);
elsif type2 == FPType_QNaN then
  done = TRUE; result = FPProcessNaN(type2, op2, fpcr);
elsif type3 == FPType_QNaN then
  done = TRUE; result = FPProcessNaN(type3, op3, fpcr);
else
  done = FALSE; result = Zeros(); // 'Don't care' result
return (done, result);

Floating-point rounding

The FPRound() function rounds and encodes a floating-point result value to a specified destination format. This
includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero
processing on result values.

// FPRound()
// =========
// Convert a real number OP into an N-bit floating-point value using the
// supplied rounding mode RMODE.

bits(N) FPRound(real op, FPCRType fpcr, FPRounding rounding)
assert N IN {16,32,64};
assert op != 0.0;
assert rounding != FPRounding_TIEAWAY;
bits(N) result;

// Obtain format parameters - minimum exponent, numbers of exponent and fraction bits.
if N == 16 then
  minimum_exp = -14; E = 5; F = 10;
elsif N == 32 then
  minimum_exp = -126; E = 8; F = 23;
else // N == 64
  minimum_exp = -1022; E = 11; F = 52;

// Split value into sign, unrounded mantissa and exponent.
if op < 0.0 then
  sign = '1'; mantissa = -op;
else
...
sign = '0'; mantissa = op;
exponent = 0;
while mantissa < 1.0 do
    mantissa = mantissa * 2.0; exponent = exponent - 1;
while mantissa >= 2.0 do
    mantissa = mantissa / 2.0; exponent = exponent + 1;

// Deal with flush-to-zero.
if fpcr.FZ == '1' && N != 16 && exponent < minimum_exp then
    // Flush-to-zero never generates a trapped exception
    if UsingAArch32() then
        FPSCR.UFC = '1';
    else
        FPSR.UFC = '1';
    return FPZero(sign);

// Start creating the exponent value for the result. Start by biasing the actual exponent
// so that the minimum exponent becomes 1, lower values 0 (indicating possible underflow).
bias_exp = Max(exponent - minimum_exp + 1, 0);
if bias_exp == 0 then mantissa = mantissa / 2^(minimum_exp - exponent);
// Get the unrounded mantissa as an integer, and the "units in last place" rounding error.
int_mant = RoundDown(mantissa * 2^F); // < 2^F if biased_exp == 0, >= 2^F if not
error = mantissa * 2^F - int_mant;
// Underflow occurs if exponent is too small before rounding, and result is inexact or
// the Underflow exception is trapped.
if bias_exp == 0 && (error != 0.0 || fpcr.UFE == '1') then
    FPProcessException(FPExc_Underflow, fpcr);

// Round result according to rounding mode.
case rounding of
    when FPRounding_TIEEVEN
        round_up = (error > 0.5 || (error == 0.5 && int_mant<0> == '1'));
        overflow_to_inf = TRUE;
    when FPRounding_POSINF
        round_up = (error != 0.0 && sign == '0');
        overflow_to_inf = (sign == '0');
    when FPRounding_NEGINF
        round_up = (error != 0.0 && sign == '1');
        overflow_to_inf = (sign == '1');
    when FPRounding_ZERO, FPRounding_ODD
        round_up = FALSE;
        overflow_to_inf = FALSE;
if round_up then
    int_mant = int_mant + 1;
    if int_mant == 2^F then // Rounded up from denormalized to normalized
        biased_exp = 1;
    if int_mant == 2^(F+1) then // Rounded up to next exponent
        biased_exp = biased_exp + 1; int_mant = int_mant DIV 2;
// Handle rounding to odd aka Von Neumann rounding
if error != 0.0 && rounding == FPRounding_ODD then
    int_mant<0> = '1';
// Deal with overflow and generate result.
if N != 16 || fpcr.AHP == '0' then // Single, double or IEEE half precision
    if biased_exp >= 2^E - 1 then
        result = if overflow_to_inf then FPInfinity(sign) else FPMAXNormal(sign);
        FPProcessException(FPExc_Overflow, fpcr);
        error = 1.0; // Ensure that an Inexact exception occurs
    else
        result = sign : biased_exp<31:F-2:0> : int_mant<F-1:0>;
    else // Alternative half precision
        if biased_exp >= 2^E then
            result = sign : Ones(N-1);
            FPProcessException(FPExc_InvalidOp, fpcr);
error = 0.0; // Ensure that an Inexact exception does not occur
else
  result = sign : biased_exp<N-F-2:0> : int_mant<F-1:0>;

// Deal with Inexact exception.
if error != 0.0 then
  FPProcessException(FPExc_Inexact, fpcr);
return result;

// FPRound()
// =========

bits(N) FPRound(real op, FPCRType fpcr)
  return FPRound(op, fpcr, FPRoundingMode(fpcr));

Selection of ARM standard floating-point arithmetic

The StandardFPSCRValue() function returns the FPSCR value that selects ARM standard floating-point arithmetic. Most of the arithmetic functions have a Boolean fpscr_controlled argument that is TRUE for Floating-point operations and FALSE for Advanced SIMD operations, and that selects between using the real FPSCR value and this value.

// StandardFPSCRValue()
// ================

FPCRType StandardFPSCRValue()
  return '00000' : FPSCR.AHP : '11000000000000000000000000';

Floating-point comparisons

The FPCompare() function compares two floating-point numbers, producing a \{N, Z, C, V\} Condition flags result as shown in Table E1-4:

<table>
<thead>
<tr>
<th>Comparison result</th>
<th>N</th>
<th>Z</th>
<th>C</th>
<th>V</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equal</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Less than</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Greater than</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Unordered</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

This result defines the operation of the VCMP floating-point instruction. The VCMP instruction writes these flag values in the FPSCR. After using a VMRS instruction to transfer them to the APSR, they can control conditional execution as shown in Table F2-1 on page F2-2517.

// FPCompare()
// ===========

bits(4) FPCompare(bits(N) op1, bits(N) op2, boolean signal_nans, FPCRType fpcr)
  assert N IN \{32,64\};
  (type1,sign1,value1) = FPUnpack(op1, fpcr);

### Floating-point reciprocal estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The VRECPE instruction produces the initial estimate of the reciprocal. It uses the following pseudocode functions:

```c
// FPRecipEstimate()
// ===============

bits(N) FPRecipEstimate(bits(N) operand, FPCRType fpcr)
assert N IN {32, 64};
(type,sign,value) = FPUnpack(operand, fpcr);
if type == FPType_SNaN || type == FPType_QNaN then
  result = FPProcessNaN(type, operand, fpcr);
elsif type == FPType_Infinity then
  result = FPZero(sign);
elsif type == FPType_Zero then
  result = FPInfinity(sign);
  FPProcessException(FPExc_DivideByZero, fpcr);
elsif (N == 32 && Abs(value) < 2.0^-128)
|| (N == 64 && Abs(value) < 2.0^-1024) then
  case FPRoundingMode(fpcr) of
    when FPRounding_TIEEVEN
      overflow_to_inf = TRUE;
    when FPRounding_POSINF
      overflow_to_inf = (sign == '0');
    when FPRounding_NEGINF
      overflow_to_inf = (sign == '1');
    when FPRounding_ZERO
      overflow_to_inf = FALSE;
  result = if overflow_to_inf then FPInfinity(sign) else FPMaxNormal(sign);
  FPProcessException(FPExc_Overflow, fpcr);
  FPProcessException(FPExc_Inexact, fpcr);
elsif fpcr.FZ == '1'
  && ((N == 32 && Abs(value) >= 2.0^128)
   || (N == 64 && Abs(value) >= 2.0^1022)) then
    // Result flushed to zero of correct sign
    result = FPZero(sign);
    FPProcessException(FPExc_Underflow, fpcr);
else
  // Scale to a double-precision value in the range 0.5 <= x < 1.0, and calculate result exponent. Scaled value has copied sign bit,
  // exponent = 1022 = double-precision biased version of -1,
  // fraction = original fraction extended with zeros.
  if N == 32 then
    fraction = operand<22:0> : Zeros(29);
    exp = UInt(operand<30:23>);
  else // N == 64
    fraction = operand<51:0>;
    exp = UInt(operand<62:52>);

if N == 32 then
  result_exp = 253 - exp;     // In range 253-254 = -1 to 253+1 = 254
else // N == 64
  result_exp = 2045 - exp;    // In range 2045-2046 = -1 to 2045+1 = 2046

// Call C function to get reciprocal estimate of scaled value.
// Input is rounded down to a multiple of 1/512.
estimate = recip_estimate(scaled);

// Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
// Convert to scaled single-precision result with copied sign bit and high-order
// fraction bits, and exponent calculated above.
fraction = estimate<51:0>;
if result_exp == 0 then
  fraction = '1' : fraction<51:1>;
elsif result_exp == -1 then
  fraction = '01' : fraction<51:2>;
  result_exp = 0;
if N == 32 then
  result = sign : result_exp<N-25:0> : fraction<51:29>;
else // N == 64
  result = sign : result_exp<N-54:0> : fraction<51:0>;
return result;

// UnsignedRecipEstimate()
// =======================
bits(32) UnsignedRecipEstimate(bits(32) operand)

if operand<31> == '0' then  // Operands <= 0x7FFFFFFF produce 0xFFFFFFFF
  result = Ones(32);
else
  dp_operand = '0 0111111110' : operand<30:0> : Zeros(21);
  estimate = recip_estimate(scaled);
  // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
  // Multiply by 2^31 and convert to an unsigned integer - this just involves
  // concatenating the implicit units bit with the top 31 fraction bits.
  result = '1' : estimate<51:21>;
return result;

recip_estimate() is defined by the following C function:

double recip_estimate(double a)
{
  int q, s;
  double r;
  q = (int)(a * 512.0);     /* a in units of 1/512 rounded down */
  r = 1.0 / (((double)q + 0.5) / 512.0); /* reciprocal r */
  s = (int)(256.0 * r + 0.5);  /* r in units of 1/256 rounded to nearest */
  return (double)s / 256.0;
}
Table E1-5 shows the results where input values are out of range.

a. **FPSCR.DZC** is set to 1

The Newton-Raphson iteration:

\[ x_{n+1} = x_n \left(2 - dx_n\right) \]

converges to \((1/d)\) if \(x_0\) is the result of VRECPE applied to \(d\).

The VRECPS instruction performs a \((2 - \text{op1} \times \text{op2})\) calculation and can be used with a multiplication to perform a step of this iteration. The functionality of this instruction is defined by the following pseudocode function:

```cpp
// FPRecipStep()
// =============

bits(32) FPRecipStep(bits(32) op1, bits(32) op2)
    FPCRType fpcr = StandardFPSCRValue();
    (type1,sign1,value1) = FPUnpack(op1, fpcr);
    (type2,sign2,value2) = FPUnpack(op2, fpcr);
    (done,result) = FPProcessNaNs(type1, type2, op1, op2, fpcr);
    if !done then
        inf1 = (type1 == FPType_Infinity);
        inf2 = (type2 == FPType_Infinity);
        zero1 = (type1 == FPType_Zero);
        zero2 = (type2 == FPType_Zero);
        bits(32) product;
        if (inf1 && zero2) || (zero1 && inf2) then
            product = FPZero('0');
        else
            product = FPMul(op1, op2, fpcr);
        result = FPSub(FPTwo('0'), product, fpcr);
        return result;
```

Table E1-6 shows the results where input values are out of range.

Floating-point square root

```cpp
// FPSqrt()
// =========
```
bits(N) FPSqrt(bits(N) op, FPCRType fpcr)
assert N IN (32,64);
(type,sign,value) = FPUnpack(op, fpcr);
if type == FPTYPE_SNaN || type == FPTYPE_QNaN then
    result = FPProcessNaN(type, op, fpcr);
elsif type == FPTYPE_Zero then
    result = FPZero(sign);
elsif type == FPTYPE_Infinity && sign == '0' then
    result = FPInfinity(sign);
elsif sign == '1' then
    result = FPDefaultNaN();
    FPProcessException(FPExc_InvalidOp, fpcr);
else
    result = FPRound(Sqrt(value), fpcr);
return result;

Floating-point reciprocal square root estimate and step
The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.
The VRSQRTE instruction produces the initial estimate of the reciprocal of the square root. It uses the following pseudocode functions:

// FPRSqrtEstimate()
// =============
bits(N) FPRSqrtEstimate(bits(N) operand, FPCRType fpcr)
assert N IN (32, 64);
(type,sign,value) = FPUnpack(operand, fpcr);
if type == FPTYPE_SNaN || type == FPTYPE_QNaN then
    result = FPProcessNaN(type, operand, fpcr);
elsif type == FPTYPE_Zero then
    result = FPInfinity(sign);
    FPProcessException(FPExc_DivideByZero, fpcr);
elsif sign == '1' then
    result = FPDefaultNaN();
    FPProcessException(FPExc_InvalidOp, fpcr);
elsif type == FPTYPE_Infinity then
    result = FPZero('0');
else
    // Scale to a double-precision value in the range 0.25 <= x < 1.0, with the 
    // evenness or oddness of the exponent unchanged, and calculate result exponent.
    // Scaled value has copied sign bit, exponent = 1022 or 1021 = double-precision 
    // biased version of -1 or -2, fraction = original fraction extended with zeros.
    if N == 32 then
        fraction = operand<22:0> : Zeros(29);
        exp = UInt(operand<30:23>);
    else // N == 64
        fraction = operand<51:0>;
        exp = UInt(operand<62:52>);
    if exp == 0 then
        while fraction<31> == 0 do
            fraction = fraction<30:0> : '0';
            exp = exp - 1;
        fraction = fraction<50:0> : '0';
    if exp<0> == '0' then
        scaled = '0' : '01111111110' : fraction<51:44> : Zeros(44);
    else
        scaled = '0' : '01111111111' : fraction<51:44> : Zeros(44);
    if N == 32 then
        result_exp = (380 - exp) DIV 2;
else // N == 64
    result_exp = (3068 - exp) DIV 2;

    // Call C function to get reciprocal estimate of scaled value.
    estimate = recip_sqrt_estimate(scaled);

    // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
    // Convert to scaled single-precision result with copied sign bit and high-order
    // fraction bits, and exponent calculated above.
    if N == 32 then
        result = '0' : result_exp<N-25:0> : estimate<51:29>;
    else // N == 64
        result = '0' : result_exp<N-54:0> : estimate<51:0>;
    return result;

// UnsignedRsqrtEstimate()
// ================

bits(32) UnsignedRsqrtEstimate(bits(32) operand)

    if operand<31:30> == '00' then // Operands <= 0x3FFFFFFF produce 0xFFFFFFFF
        result = Ones(32);
    else
        // Generate double-precision value = operand * 2^(-32). This has zero sign bit, with:
        //     exponent = 1022 or 1021 = double-precision representation of 2^(-1) or 2^(-2)
        //     fraction taken from operand, excluding its most significant one or two bits.
        if operand<31> == '1' then
            dp_operand = '0 01111111110' : operand<30:0> : Zeros(21);
        else // operand<31:30> == '01'
            dp_operand = '0 01111111101' : operand<29:0> : Zeros(22);

        // Call C function to get reciprocal estimate of scaled value.
        estimate = recip_sqrt_estimate(dp_operand);

        // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
        // Multiply by 2^31 and convert to an unsigned integer - this just involves
        // concatenating the implicit units bit with the top 31 fraction bits.
        result = '1' : estimate<51:21>;

        return result;
    
recip_sqrt_estimate() is defined by the following C function:

    double recip_sqrt_estimate(double a)
    {
        int q0, q1, s;
        double r;
        if (a < 0.5) /* range 0.25 <= a < 0.5 */
            { q0 = (int)(a * 512.0); /* a in units of 1/512 rounded down */
                r = 1.0 / sqrt(((double)q0 + 0.5) / 512.0); /* reciprocal root r */
            }
        else /* range 0.5 <= a < 1.0 */
            { q1 = (int)(a * 256.0); /* a in units of 1/256 rounded down */
                r = 1.0 / sqrt(((double)q1 + 0.5) / 256.0); /* reciprocal root r */
            }
        s = (int)(256.0 * r + 0.5); /* r in units of 1/256 rounded to nearest */
        return (double)s / 256.0;
    }
The Newton-Raphson iteration:

\[ x_{n+1} = x_n \left( \frac{3 - dx_n^2}{2} \right) \]

converges to \( \frac{1}{\sqrt{d}} \) if \( x_0 \) is the result of \( \text{VRSQRTE} \) applied to \( d \).

The VRSQRTS instruction performs a \( \frac{3 - \text{op1} \times \text{op2}}{2} \) calculation and can be used with two multiplications to perform a step of this iteration. The \text{FPRSqrtStep()}\ pseuocode function defines the functionality of this instruction:

```c
// FPRSqrtStep()
// =============
bits(32) FPRSqrtStep(bits(32) op1, bits(32) op2)
FPCRType fpcr = StandardFPSCRValue();
(type1,sign1,value1) = FPUnpack(op1, fpcr);
(type2,sign2,value2) = FPUnpack(op2, fpcr);
(done,result) = FPProcessNaNs(type1, type2, op1, op2, fpcr);
if !done then
    inf1 = (type1 == FPType_Infinity);  inf2 = (type2 == FPType_Infinity);
    zero1 = (type1 == FPType_Zero);     zero2 = (type2 == FPType_Zero);
    bits(32) product;
    if (inf1 && zero2) || (zero1 && inf2) then
        product = FPZero('0');
    else
        product = FPMul(op1, op2, fpcr);
    result = FPHalvedSub(FPThree('0'), product, fpcr);
return result;
```

Table E1-7 shows the results where input values are out of range.

FPRSqrtStep() calls the FPHalvedSub() pseudocode function:

```c
// FPHalvedSub()
// =============
```
bits(N) FPHalvedSub(bits(N) op1, bits(N) op2, FPCRType fpcr)
assert N IN \{32,64\};
rounding = FPRoundingMode(fpcr);
(type1,sign1,value1) = FPUnpack(op1, fpcr);
(type2,sign2,value2) = FPUnpack(op2, fpcr);
(done,result) = FPProcessNaNs(type1, type2, op1, op2, fpcr);
if !done then
  inf1 = (type1 == FPTyp infinity);  inf2 = (type2 == FPTyp infinity);
  zero1 = (type1 == FPTyp zero);     zero2 = (type2 == FPTyp zero);
  if inf1 & inf2 & sign1 == sign2 then
    result = FPDefaultNaN();
    FPProcessException(FPExc_InvalidOp, fpcr);
  elsif (inf1 && sign1 == '0') || (inf2 && sign2 == '1') then
    result = FPIfinity('0');
  elsif (inf1 && sign1 == '1') || (inf2 && sign2 == '0') then
    result = FPIfinity('1');
  elsif zero1 && zero2 && sign1 != sign2 then
    result = FPZero(sign1);
  else
    result_value = (value1 - value2) / 2.0;
    if result_value == 0.0 then  // Sign of exact zero result depends on rounding mode
      result_sign = if rounding == FPRounding_NEGINF then '1' else '0';
      result = FPZero(result_sign);
    else
      result = FPRound(result_value, fpcr);
    return result;

Floating-point conversions

The following function performs conversions between half-precision, single-precision and double-precision floating-point numbers.

// FPConvert()
// ===========
// Convert floating point OP with N-bit precision to M-bit precision,
// with rounding controlled by ROUNding.

bits(M) FPConvert(bits(N) op, FPCRType fpcr, FPRounding rounding)
assert M IN \{16,32,64\};
assert N IN \{16,32,64\};
bits(M) result;

// Unpack floating-point operand optionally with flush-to-zero.
(type,sign,value) = FPUnpack(op, fpcr);
alt_hp = (M == 16) && (fpcr.AHP == '1');
if type == FPTyp_SNaN || type == FPTyp_QNaN then
  if alt_hp then
    result = FPZero(sign);
  elsif fpcr.DN == '1' then
    result = FPDefaultNaN();
  else
    result = FPConvertNaN(op);
  FPProcessException(FPExc_InvalidOp,fpcr);
elsif type == FPTyp_Infinit then
  if alt_hp then
    result = sign:Ones(M-1);
    FPProcessException(FPExc_InvalidOp, fpcr);
  else
    result = FPIfinity(sign);
  else if type == FPTyp_Zero then
    result = FPZero(sign);
  else

result = FPRound(value, fpcr, rounding);

return result;

// FPConvert()
// =========

bits(M) FPConvert(bits(N) op, FPCRType fpcr)
    return FPConvert(op, fpcr, FPRoundingMode(fpcr));

The following functions perform conversions between floating-point numbers and integers or fixed-point numbers:

// FPToFixed()
// =========

// Convert N-bit precision floating point OP to M-bit fixed point with
// FBITS fractional bits, controlled by UNSIGNED and ROUNDBG.

bits(M) FPToFixed(bits(N) op, integer fbits, boolean unsigned, FPCRType fpcr, FPRounding rounding)
assert N IN {32,64};
assert M IN {32,64};
assert fbits >= 0;
assert rounding != FPRounding_ODD;

// Unpack using fpcr to determine if subnormals are flushed-to-zero
(type,sign,value) = FPUnpack(op, fpcr);

// If NaN, set cumulative flag or take exception
if type == FPType_SNaN || type == FPType_QNaN then
    FPProcessException(FPExc_InvalidOp, fpcr);

// Scale by fractional bits and produce integer rounded towards minus-infinity
value = value * 2^fbits;
int_result = RoundDown(value);
error = value - int_result;

// Determine whether supplied rounding mode requires an increment
case rounding of
    when FPRounding_TIEEVEN
        round_up = (error > 0.5 || (error == 0.5 && int_result<0> == '1'));
    when FPRounding_POSINF
        round_up = (error != 0.0);
    when FPRounding_NEGINF
        round_up = FALSE;
    when FPRounding_ZERO
        round_up = (error != 0.0 && int_result < 0);
    when FPRounding_TIEAWAY
        round_up = (error > 0.5 || (error == 0.5 && int_result >= 0));

if round_up then int_result = int_result + 1;

// Generate saturated result and exceptions
(result, overflow) = SatQ(int_result, M, unsigned);
if overflow then
    FPProcessException(FPExc_InvalidOp, fpcr);
elsif error != 0.0 then
    FPProcessException(FPExc_Inexact, fpcr);

return result;

// FixedToFP()
// =========

// Convert M-bit fixed point OP with FBITS fractional bits to
// N-bit precision floating point, controlled by UNSIGNED and ROUNDBG.

bits(N) FixedToFP(bits(M) op, integer fbits, boolean unsigned, FPCRType fpcr, FPRounding rounding)
assert N IN {32,64};
assert M IN {32,64};
bits(N) result;
assert fbits >= 0;
assert rounding != FPRounding_ODD;

// Correct signed-ness
int_operand = Int(op, unsigned);

// Scale by fractional bits and generate a real value
real_operand = int_operand / 2^fbits;

if real_operand == 0.0 then
  result = FPZero('0');
else
  result = FPRound(real_operand, fpcr, rounding);

return result;
E1.4 Conceptual coprocessor support

AArch32 state provides a coprocessor interface, that comprises the coprocessor instructions summarized in
Coprocessor instructions on page F1-2496. These can provide access to sixteen conceptual coprocessors, described
as CP0 to CP15. The following coprocessors are reserved by ARM for specific purposes, and from ARMv8 are the
only supported coprocessors:

• Coprocessor 15 (CP15) provides system control functionality, by providing access to System registers. This
includes architecture and feature identification, as well as control, status information and configuration
support.

The following sections give a general description of CP15:
— About the System registers for VMSA v8-32 on page G4-4188.
— Organization of the CP15 registers in VMSA v8-32 on page G4-4212.
— Functional grouping of VMSA v8-32 System registers on page G4-4231.

CP15 also provides performance monitor registers, see Chapter D5 The Performance Monitors Extension.

• Coprocessor 14 (CP14) provides access to additional registers, that support:
— Debug, see Chapter G2 AArch32 Self-hosted Debug.
— The Jazelle identification registers, see Jazelle support on page E1-2392.

• Coprocessors 10 and 11 (CP10 and CP11) together support floating-point and Advanced SIMD vector
operations, and the control and configuration of Advanced SIMD and floating-point operation.

Note

To enable use of the Advanced SIMD and floating-point instructions, software must enable access to both CP10 and
CP11, see Enabling Advanced SIMD and floating-point support on page G1-3914.

UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses on page G4-4190 gives information
more information about permitted accesses to coprocessors CP14 and CP15.

Most CP14 and CP15 functions cannot be accessed by software executing at EL0. This manual clearly identifies
those functions that can be accessed at EL0. However, software executing at EL1 can enable the unprivileged
execution of all load, store, branch and data operation instructions associated with floating-point, Advanced SIMD
and execution environment support.
E1.5 Exceptions

The ARM architecture uses the following terms to describe various types of exceptional condition:

**Exceptions**

In the ARM architecture, an *exception* causes entry to EL1, EL2, or EL3. If the Exception level that is entered is using AArch32, it also causes entry to the PE mode in which the exception must be taken. A software handler for the exception is then executed.

--- Note ---

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

---

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), Secure Monitor calls (SMCs), and hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in Handling exceptions that are taken to an Exception level using AArch32 on page G1-3841. In an ARMv8 implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The SVC instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The SMC instruction causes a Secure Monitor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at EL1 or higher.
- The HVC instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The BKPT instruction causes a Software Breakpoint Instruction exception, that is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The WFI (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wake-up event occurs, see Wait For Interrupt on page G1-3909. This means the hardware might enter a low-power state until the wake-up event occurs.
- The WFE (Wait for Event) instruction provides a hint that nothing needs to be done until either an SEV instruction generates an event, or another WFE wake-up event occurs, see Wait For Event and Send Event on page G1-3906. This means the hardware might enter a low-power state until the wake-up event occurs.

**Floating-point exceptions**

These relate to exceptional conditions encountered during floating-point arithmetic, such as division by zero or overflow. For more information see:

- Floating-point exceptions on page E1-2398.
- FPEXC, Floating-Point Exception Control register on page G6-4380.
- FPSCR, Floating-Point Status and Control Register on page G6-4385.
Chapter E2
The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 when EL0 is using AArch32 in the following sections:

- Address space on page E2-2426.
- Memory type overview on page E2-2429.
- Caches and memory hierarchy on page E2-2430.
- Alignment support on page E2-2435.
- Endian support on page E2-2437.
- Atomicity in the ARM architecture on page E2-2440.
- Memory ordering on page E2-2444.
- Memory types and attributes on page E2-2453.
- Mismatched memory attributes on page E2-2463.
- Synchronization and semaphores on page E2-2466

--- Note ---

In this chapter, system register names usually link to the description of the register in Chapter G6 AArch32 System Register Descriptions, for example SCTLR.
E2.1 Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo \(2^{32}\).

The result of an address calculation is **UNKNOWN** if it overflows or underflows the 32-bit address range \(A[31:0]\).

Memory accesses use the `MemA[]`, `MemO[]`, `MemU[]`, and `MemU_unpriv[]` functions:

- The `MemA[]` function makes an aligned access of the required type.
- The `MemO[]` function makes an ordered access of the required type.
- The `MemU[]` function makes an unaligned access of the required type.
- The `MemU_unpriv[]` function makes an unaligned, unprivileged access of the required type.

Each of these functions calls `Mem_with_type[]` that specifies the required access. These also call `MemSingle[]` which performs an atomic, little-endian read of "size" bytes.

```
// MemA[] - non-assignment form
// ============================
bits(8*size) MemA[bits(32) address, integer size]
   acctype = AccType_ATOMIC;
   return Mem_with_type[address, size, acctype];

// MemA[] - assignment form
// ========================
MemA[bits(32) address, integer size] = bits(8*size) value
   acctype = AccType_ATOMIC;
   Mem_with_type[address, size, acctype] = value;
   return;

// MemO[] - non-assignment form
// ============================
bits(8*size) MemO[bits(32) address, integer size]
   acctype = AccType_ORDERED;
   return Mem_with_type[address, size, acctype];

// MemO[] - assignment form
// ========================
MemO[bits(32) address, integer size] = bits(8*size) value
   acctype = AccType_ORDERED;
   Mem_with_type[address, size, acctype] = value;
   return;

// MemU[] - non-assignment form
// ============================
bits(8*size) MemU[bits(32) address, integer size]
   acctype = AccType_NORMAL;
   return Mem_with_type[address, size, acctype];

// MemU[] - assignment form
// ========================
MemU[bits(32) address, integer size] = bits(8*size) value
   acctype = AccType_NORMAL;
   Mem_with_type[address, size, acctype] = value;
   return;

// MemU_unpriv[] - non-assignment form
// =====================================
```
bits(8*size) MemU_unpriv[bits(32) address, integer size] = bits(8*size) value
acctype = AccType_UNPRIV;
Mem_with_type[address, size, acctype] = value;
return;

// MemU_unpriv[ ] assignment form
// -----------------------------------------

AArch32.MemSingle[bits(32) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8) value
assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);
AddressDescriptor memaddrdesc;
bits(size*8) value;
iswrite = FALSE;

// MMU or MPU
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
AArch32.Abort(address, memaddrdesc.fault);

// Memory array access
value = _Mem[memaddrdesc, size, acctype];
return value;

// AArch32.MemSingle[ ] assignment (write) form
// ----------------------------------------------

AArch32.MemSingle[bits(32) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8) value
assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);
AddressDescriptor memaddrdesc;
iswrite = TRUE;

// MMU or MPU
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
AArch32.Abort(address, memaddrdesc.fault);

// Effect on exclusives
if memaddrdesc.memattrs.shareable then
ClearExclusiveByAddress(memaddrdesc.paddress, ProcessorID(), size);

// Memory array access
_Mem[memaddrdesc, size, acctype] = value;
return;

The AccType enumeration defines the different access types:

enumeration AccType {AccType_NORMAL, AccType_VEC,        // Normal loads and stores
AccType_STREAM, AccType_VECSTREAM,  // Streaming loads and stores
AccType_ATOMIC,                     // Atomic loads and stores
AccType_ORDERED,                     // Load-Acquire and Store-Release

E2 The AArch32 Application Level Memory Model

E2.1 Address space

AccType_UNPRIV, // Load and store unprivileged
AccTypeIFnCH,    // Instruction fetch
AccType_PTW,     // Page table walk
// Other operations
AccType_DC,      // Data cache maintenance
AccType_IC,      // Instruction cache maintenance
AccType_AT};     // Address translation

--- Note ---

- Chapter G3 The AArch32 System Level Memory Model and Chapter G4 The AArch32 Virtual Memory System Architecture include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.

- For information on the pseudocode that relates to memory accesses, see Basic memory access on page G3-4051, Unaligned memory access on page G3-4052, and Aligned memory access on page G3-4051.
### E2.2 Memory type overview

ARMv8 provides the following mutually-exclusive memory types:

- **Normal**
  - This is generally used for bulk memory operations, both read-write and read-only operations.

- **Device**
  - The ARM architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.
  - Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.
  - Device memory has additional attributes that have the following effects:
    - They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See [Gathering on page E2-2460](#).
    - They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See [Reordering on page E2-2461](#).
    - They indicate whether a write can be acknowledged other than at the end point. See [Early Write Acknowledgement on page E2-2461](#).
  - For more information on Normal memory and Device memory, see [Memory types and attributes on page E2-2453](#).

---

**Note**

Earlier versions of the ARM architecture defined a single Device memory type and a Strongly-Ordered memory type. A Note in [Device memory on page E2-2458](#) describes how these memory types map onto the ARMv8 memory types.
E2.3 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. ARMv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Implication of caches for the application programmer on page E2-2432.
- Preloading caches on page E2-2433.

E2.3.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a tag.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. ARMv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

E2.3.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure E2-1 on page E2-2431 shows an example of such a system in an ARMv8-A system that supports virtual addressing.
In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in Figure E2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined by two conceptual points:

**Point of Unification (PoU)**

The point at which the instruction cache, data cache, and translation table walks of a particular PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged. The point of unification might coincide with the point of coherency.

**Point of Coherency (PoC)**

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

---

**Note**

The presence of system caches can affect the definition of the point of coherency as described in System level caches on page D3-1710.

See also The ARMv8 cache maintenance functionality on page G3-4029.

**The cacheability and shareability memory attributes**

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

- **Cacheability**
  
  This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer cacheability locations.

- **Shareability**
  
  This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer shareability domains.

  - For more information about cacheability and shareability see Memory types and attributes on page E2-2453.
E2.3.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  — Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  — Not enabling caches in the system.
- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory on page E2-2455 and Shareable, Inner Shareable, and Outer Shareable Normal memory on page E2-2454.

Note

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context synchronization operation on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using the ISR and DSISR memory barriers and cache maintenance instructions. These can only be accessed from an Exception level that is higher than EL0, and therefore require a system call, see Exception-generating and exception-handling instructions on page F1-2495. The following code sequence can be used for this purpose:

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCCMVAU Rn ; Clean data cache by MVA to point of unification (PoU)
DSB ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn ; Invalidate instruction cache by MVA to PoU
BPIINV Rn ; Invalidate branch predictor by MVA to PoU
DSB ; Ensure completion of the invalidations
ISB ; Synchronize the fetched instruction stream

--- Note ---
• For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.
• This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See Concurrent modification and execution of instructions on page E2-2442.

### E2.3.4 Preloading caches

The ARM architecture provides the memory system hints PLD (Preload Data), PLDW (Preload Data With Intent To Write) and PLI (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous external abort, which is taken using an asynchronous Data Abort exception. For more information, see Data Abort exception on page G1-3887.

A PLD, PLDW, or PLI instruction can only cause allocation to software-visible caching structures such as caches or TLBs for memory locations that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

• Reads.
• Writes.
• Instruction fetches.

A PLD, PLDW, or PLI instruction can access any memory location in Normal memory that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

• Reads.
• Writes.
• Instruction fetches.

--- Note ---
In each case, the entire list applies to each of PLD, PLDW, and PLI.

---

A PLD, PLDW, or PLI instruction is guaranteed not to access any type of Device memory.

A PLI instruction must not perform any access that cannot be performed by a speculative instruction fetch by the processor. Therefore in a VMSA implementation, if all associated MMUs are disabled, a PLI instruction cannot access any memory location that cannot be accessed by instruction fetches.
PrefetchHint defines the prefetch hint types:

```
enumeration PrefetchHint {Prefetch_READ, Prefetch_WRITE, Prefetch_EXEC};
```

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

```
Hint_Prefetch(bits(64) address, PrefetchHint hint, integer target, boolean stream);
```

For more information on PLD, PLI, and PLDW, see:

- `PLD, PLDW (immediate)` on page F7-2928.
- `PLD (literal)` on page F7-2930.
- `PLD, PLDW (register)` on page F7-2932.
- `PLI (immediate, literal)` on page F7-2934.
- `PLI (register)` on page F7-2937.
E2.4 Alignment support

This section describes alignment support. It contains the following subsections:

- Instruction alignment.
- Unaligned data access.
- Cases where unaligned accesses are UNPREDICTABLE on page E2-2436.
- Unaligned data access restrictions on page E2-2436.

E2.4.1 Instruction alignment

A32 instructions are word-aligned.

T32 instructions are halfword-aligned.

E2.4.2 Unaligned data access

An ARMv8 implementation must support unaligned data accesses to Normal memory by some load and store instructions, as Table E2-1 shows. Software can set SCTLR.A or HSCTLR.A to control whether a misaligned access to Normal memory by one of these instructions causes an Alignment fault Data Abort exception.

### Table E2-1 Alignment requirements of load/store instructions

<table>
<thead>
<tr>

<tr>
<td>VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :&lt;align&gt; specified a</td>
<td>As specified by :&lt;align&gt;</td>
<td>Alignment fault</td>
</tr>
</tbody>
</table>

a. Previous versions of this manual used @<align> to specify alignment. Both forms are supported, see Chapter F8 T32 and A32 Advanced SIMD and floating-point Instruction Descriptions for more information.

---

**Note**

Any unaligned access to any type of Device memory generates an Alignment fault, see Alignment faults on page G4-4158.
E2.4.3 Cases where unaligned accesses are UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in Table E2-1 on page E2-2435 and that loads the PC has UNPREDICTABLE behavior if the address it loads from is not word-aligned. This overrules any permitted Load/Store behavior shown in Table E2-1 on page E2-2435.

E2.4.4 Unaligned data access restrictions

The following points apply to unaligned data accesses in ARMv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see Atomicity in the ARM architecture on page E2-2440.
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.
E2.5 Endian support

General description of endianness in the ARM architecture describes the relationship between endianness and memory addressing in the ARM architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness.*
- *Data endianness* on page E2-2438.

E2.5.1 General description of endianness in the ARM architecture

This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure E2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in Figure E2-2 have the following definitions:

- MSByte Most-significant byte.
- LSByte Least-significant byte.

In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1*

Figure E2-2 Endianness relationships in AArch32

E2.5.2 Instruction endianness

In ARMv8-A, the mapping of instruction memory is always little-endian.
E2.5.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table E2-2 shows the element sizes of all the load/store instructions, for all instruction sets.

Table E2-2 Element size of load/store instructions

<table>

<tr>
<td>VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4</td>
<td>Element size of the Advanced SIMD access</td>
</tr>
</tbody>
</table>

CPSR.E determines the data endianness.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information see Endianness in Advanced SIMD on page E2-2439.

Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table E2-3 shows the instructions that provide this functionality in the A32 and T32 instruction sets:

Table E2-3 Byte reversal instructions

Endianness in Advanced SIMD

Advanced SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

\[
\text{VLD1.16 \{} \{D0\}, [R1] \]

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure E2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

For information about the alignment of Advanced SIMD instructions see Alignment support on page E2-2435.

The \text{BigEndian()} function determines the current endianness of the data:

\[
\text{boolean BigEndian();} \\
\]

The pseudocode function for \text{BigEndianReverse()} is as follows:

\[
// \text{BigEndianReverse() } \\
// =============== \\
\text{bits(width) BigEndianReverse (bits(width) value)} \\
\text{assert width \in \{8, 16, 32, 64, 128\};} \\
\text{integer half = width \div 2; } \\
\text{if width == 8 then return value;} \\
\text{return BigEndianReverse(value-half:1:0) : BigEndianReverse(value-width-1:half);} \\
\]

![Figure E2-3 Advanced SIMD byte order example for AArch32](image-url)
E2.6 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as atomic accesses. The ARM architecture description refers to two types of atomicity, defined in:

- Single-copy atomicity.
- Multi-copy atomicity on page E2-2441.

In the ARMv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- Memory type overview on page E2-2429.
- Requirements for single-copy atomicity.
- Requirements for multi-copy atomicity on page E2-2442.

E2.6.1 Single-copy atomicity

A read or write operation is single-copy atomic only if it meets the following conditions:

1. For a single-copy atomic store, if the store overlaps another single-copy atomic store, then all of the writes from one of the stores are inserted into the Coherence order of each overlapping byte before any of the writes of the other store are inserted into the Coherence orders of the overlapping bytes.

2. If a single-copy atomic load overlaps a single-copy atomic store and for any of the overlapping bytes the load returns the data written by the write inserted into the Coherence order of that byte by the single-copy atomic store then the load must return data from a point in the Coherence order no earlier than the writes inserted into the Coherence order by the single-copy atomic store of all of the overlapping bytes.

E2.6.2 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by LDREXD and STREXD instructions to doubleword-aligned locations.

LDM, LDC, LDC2, LDRD, STM, STC, STC2, STRD, PUSH, POP, RFE, SRS, VLDM, VLDR, VSTM, and VSTR instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

LDRD and STRD accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

**Note**

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.

- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.
Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 64 bits, or smaller.
- The elements are naturally aligned.

Accesses to 64-bit elements or structures that are 32-bit aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic. The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic by the rules described in this section, it is executed as a sequence of one or more accesses that aggregate to the size of the original access. Each of the accesses in this sequence is single-copy atomic, at least at the byte level.

--- Note

In this section, the terms before the write operation and after the write operation mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

---

If, according to these rules, an instruction is executed as a sequence of accesses, a synchronous Data Abort exception or Debug state entry can be taken during that sequence. This causes execution of the instruction to be abandoned. See Data Abort exception on page G1-3887.

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated. This also applies to an exit from Debug state.

--- Note

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

---

For implicit accesses:

- Cache line fills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.

- Instruction fetches are single-copy atomic:
  - At 32-bit granularity in A32 state.
  - At 16-bit granularity in T32 state.

- Concurrent modification and execution of instructions on page E2-2442 describes additional constraints on the behavior of instruction fetches.

- Translation table walks are performed using accesses that are single-copy atomic:
  - At 32-bit granularity when using Short-descriptor format translation tables.
  - At 64-bit granularity when using Long-descriptor format translation tables.

---

**E2.6.3 Multi-copy atomicity**

In a multiprocessing system, writes to a memory location are multi-copy atomic if the following conditions are both true:

- All writes to the same location are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.

- A read of a location does not return the value of a write until all observers observe that write.

--- Note

Writes that are not coherent are not multi-copy atomic.
E2.6.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory with the non-Gathering attribute, writes that are single-copy atomic are also multi-copy atomic.

For Device memory with the Gathering attribute, writes are not required to be multi-copy atomic.

E2.6.5 Concurrent modification and execution of instructions

The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification or the instruction after modification is a:

- B, BL, NOP, BKPT, SVC, HVC, or SMC A32 instruction
- B, BL, BLX, NOP, BKPT, or SVC 16-bit T32 instruction.

In addition, for the T32 instructions:

- The most-significant halfword of a 32-bit BL immediate instruction can be concurrently modified to the most significant halfword of another BL immediate instruction:
  - This means that the most significant bits of the immediate value can be modified.

- The most-significant halfword of a 32-bit BLX immediate instruction can be concurrently modified to the most significant halfword of another BLX immediate instruction:
  - This means that the most significant bits of the immediate value can be modified.

- The most-significant halfword of a 32-bit BL immediate or BLX immediate instruction can be concurrently modified to a T32 16-bit B, BL, BLX, BKPT, or SVC instruction. This modification also works in reverse.

- The least-significant halfword of a 32-bit BL immediate instruction can be concurrently modified to the least significant halfword of another BL instruction with a different immediate:
  - This means that the least significant bits of the immediate value can be modified.

- The least-significant halfword of a 32-bit BLX immediate instruction can be concurrently modified to the least significant halfword of another BLX immediate instruction with a different immediate:
  - This means that the least significant bits of the immediate value can be modified.

- The least-significant halfword of a 32-bit BL immediate or BLX immediate instruction with a condition field can be concurrently modified to the least significant halfword of another 32-bit BL immediate instruction with a different immediate:
  - This means that the least significant bits of the immediate value can be modified.

- The least-significant halfword of a 32-bit BL immediate instruction without a condition field can be concurrently modified to the least significant halfword of another 32-bit BL immediate instruction without a condition field:
  - This means that the least significant bits of the immediate value can be modified.

---

Note

In the T32 instruction set:

- The only encodings of BKPT and SVC are 16-bit.
- The only encoding of BL is 32-bit.

---

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.
The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

For all other instructions, to avoid UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, the PE that modified the instructions must issue the following sequence of instructions and operations:

   ; Coherency example for self-modifying code
   ; Enter this code with <Rt> containing a new 32-bit instruction,
   ; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first
   ; line instead of STR for a 16-bit instruction.
   STR <Rt>, [Rn]
   DCCMVAU Rn                 ; Clean data cache by MVA to point of unification (PoU)
   DSB                        ; Ensure visibility of the data stored
   ICIMVAU Rn                 ; Invalidate instruction cache by VA to PoU
   BPIMVA  Rn                 ; Invalidate branch predictor by MVA to PoU
   DSB                        ; Ensure completion of the invalidations

   ______ Note _______

   The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-through Cacheable.

3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

   ISB                             ; Synchronize fetched instruction stream

For more information about the required synchronization operation, see Synchronization and coherency issues between data and instruction accesses on page E2-2432.

   ______ Note _______

For information about memory accesses caused by instruction fetches, see Ordering requirements on page E2-2445.
E2.7 Memory ordering

This section describes observation ordering. It contains the following subsections:

- Observability and completion.
- Ordering requirements on page E2-2445.
- Memory barriers on page E2-2446.
- Summary of the memory ordering rules on page E2-2450.

For information on endpoint ordering of memory accesses, see Reordering on page E2-2461.

In the ARMv8 memory model, the shareability memory attribute indicates whether hardware must ensure memory coherency.

The ARMv8 memory system architecture defines additional attributes and associated behaviors, defined in the system level section of this manual. See:

- Chapter G3 The AArch32 System Level Memory Model.
- Chapter G4 The AArch32 Virtual Memory System Architecture.

See also Mismatched memory attributes on page E2-2463.

E2.7.1 Observability and completion

An observer is a master in the system that is capable of observing memory accesses. For a PE, the following mechanisms must be treated as independent observers:

- The mechanism that performs reads or writes to memory.
- A mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory. These are treated as reads.
- A mechanism that performs translation table walks. These are treated as reads.

The set of observers that can observe a memory access is defined by the system.

In the definitions in this subsection, subsequent means whichever of the following is appropriate to the context:

- After the point in time where the location is observed by that observer.
- After the point in time where the location is globally observed.

For all memory:

- A write to a location in memory is said to be observed by an observer when:
  - A subsequent read of the location by the same observer returns the value written by the observed write, or written by a write to that location by any observer that is sequenced in the Coherence order of the location after the observed write.
  - A subsequent write of the location by the same observer is sequenced in the Coherence order of the location after the observed write.

- A write to a location in memory is said to be globally observed for a shareability domain or set of observers when:
  - A subsequent read of the location by any observer in that shareability domain returns the value written by the globally observed write, or written by a write to that location by any observer that is sequenced in the Coherence order of the location after the globally observed write.
  - A subsequent write of the location by any observer in that shareability domain is sequenced in the Coherence order of the location after the globally observed write.

- A read of a location in memory is said to be observed by an observer when a subsequent write to the location by the same observer has no effect on the value returned by the read.

- A read of a location in memory is said to be globally observed for a shareability domain when a subsequent write to the location by any observer in that shareability domain has no effect on the value returned by the read.
Additionally, for Device-nGnRnE memory:

- A read or write of a memory-mapped location in a peripheral that exhibits side-effects is said to be observed, and globally observed, only when the read or write:
  - Meets the general conditions listed.
  - Can begin to affect the state of the memory-mapped peripheral.
  - Can trigger all associated side-effects, whether they affect other peripheral devices, processors, or memory.

**Note**

This definition is consistent with the memory access having reached the peripheral.

For all memory, the completion rules are defined as:

- A read or write is complete for a shareability domain when all of the following are true:
  - The read or write is globally observed for that shareability domain.
  - Any translation table walks associated with the read or write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses associated with the translation table walk are globally observed for that shareability domain, and the TLB is updated.
- A cache or TLB maintenance instruction is complete for a shareability domain when the effects of the instruction are globally observed for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

The completion of any cache or TLB maintenance instruction includes its completion on all processors that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

**Completion of side-effects of accesses to Device memory**

The completion of a memory access to Device memory is not guaranteed to be sufficient to determine that the side-effects of the memory access are visible to all observers. The mechanism that ensures the visibility of side-effects of a memory access is IMPLEMENTATION DEFINED.

### E2.7.2 Ordering requirements

ARMv8 defines restrictions for the permitted ordering of memory accesses. These restrictions depend on the memory locations that are being accessed. See *Memory types and attributes* on page E2-2453.

The following additional restrictions apply to the order in which accesses to Normal memory are observed:

- Reads and writes can be observed in any order provided the following constraints are met:
  - If an address dependency exists between two reads or between a read and a write, then those memory accesses are observed in program order by all observers within the shareability domain of the memory address being accessed.
  - Writes that would not occur in a simple sequential execution of the program cannot be observed by other observers. This implies that where a control, address or data dependency exists between a read and a write, those memory accesses are observed in program order by all observers within the shareability domain of the memory addresses being accessed.
  - Ordering can be achieved by using a DMB or DSB barrier. For more information on DMB and DSB instructions, see *Memory barriers* on page E2-2446.
- Reads and writes to the same location are coherent within the shareability domain of the memory address being accessed.
- Two reads of the same location by the same observer are observed in program order by all observers within the shareability domain of the memory address being accessed.
• Writes are not required to be multi-copy atomic. This means that in the absence of barriers, the observation of a store by one observer does not imply the observation of the store by another observer.

• Instructions that access multiple elements have no defined ordering requirements for the memory accesses relative to each other.

Memory accesses caused by instruction fetches are not required to be observed in program order, unless they are separated by an ISB or other context synchronization event.

**Address dependencies and order**

In the ARMv8 architecture, a register data dependency creates order between a load instruction and a subsequent memory transaction, that is between the data value returned from the load and the address used by the subsequent memory transaction.

A register data dependency exists between a first data value and a second data value when either:

• The register used to hold the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:
  — A conditional branch whose condition is determined by the first data value.
  — A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.

• There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

Note

A register data dependency can exist even if the value of the first data value is discarded as part of the calculation, as might be the case if it is ANDed with 0x0 or if arithmetic using the first data value cancels out its contribution.

For example, each of the following code sequences creates order between the memory transactions:

**Sequence 1**
```
LDR R1, [R2]
AND R1, R1, #0
LDR R4, [R3, R1]
```

**Sequence 2**
```
LDR R1, [R2]
ADD R3, R3, R1
SUB R3, R3, R1
STR R4, [R3]
```

**E2.7.3 Memory barriers**

The ARM architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the ARMv8 architecture provide a range of functionality, including:

• Ordering of Load/Store instructions.
• Completion of Load/Store instructions.
• Context synchronization.

The following subsections describe the ARMv8 memory barrier instructions:

• *Instruction Synchronization Barrier (ISB)* on page E2-2447.
• *Data Memory Barrier (DMB)* on page E2-2447.
• *Data Synchronization Barrier (DSB)* on page E2-2448.
• *Shareability and access limitations on the data barrier operations* on page E2-2449.
• *Load-Acquire, Store-Release* on page E2-2449.
Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

AArch32 state also supports the legacy CP15 barrier operations CP15DMB, CP15DSB, and CP15ISB. These operations are accessible from EL0. However, ARM deprecates any use of these operations, and strongly recommends that software uses the DMB, DSB, and ISB instructions described in this section instead. Supervisory software can disable use of the CP15 barrier operations, meaning the encodings for these operations are unallocated:

- If EL1 is using AArch32, by setting SCTLR.CP15BEN to 0.
- If EL1 is using AArch64, by setting SCTLR_EL1.CP15BEN to 0.

Instruction Synchronization Barrier (ISB)

An ISB instruction flushes the pipeline in the PE, so that all instructions that come after the ISB instruction in program order are fetched from the cache or memory only after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to system control registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

InstructionSynchronizationBarrier();

See also Memory barriers on page G3-4058.

Data Memory Barrier (DMB)

The DMB instruction is a data memory barrier. The PE that executes the DMB instruction is referred to as the executing PE, PEe. The DMB instruction takes the required shareability domain and required access types as arguments:

DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);

See Shareability and access limitations on the data barrier operations on page E2-2449.

If the required shareability is Full system then the operation applies to all observers within the system.

A DMB creates two groups of memory accesses, Group A and Group B:

**Group A**
- Contains:
  - All explicit memory accesses of the required access types from observers in the same required shareability domain as PEe that are observed by PEe before the DMB instruction. These accesses include any accesses of the required access types performed by PEe.
  - All loads of required access types from an observer PEx in the same required shareability domain as PEe that have been observed by any given different observer, PEy, in the same required shareability domain as PEe before PEy has performed a memory access that is a member of Group A.

**Group B**
- Contains:
  - All explicit memory accesses of the required access types by PEe that occur in program order after the DMB instruction.
• All explicit memory accesses of the required access types by any given observer PEx in the same required shareability domain as PEe that can only occur after a load by PEx has returned the result of a store that is a member of Group B.

Any observer with the same required shareability domain as PEe observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a DMB NSH is sufficient for this guarantee.

--- Note ---
- A memory access might be in neither Group A nor Group B. The DMB does not affect the order of observation of such a memory access.
- The second part of the definition of Group A is recursive. Ultimately, membership of Group A derives from the observation by PEy of a load before PEy performs an access that is a member of Group A as a result of the first part of the definition of Group A.
- The second part of the definition of Group B is recursive. Ultimately, membership of Group B derives from the observation by any observer of an access by PEe that is a member of Group B as a result of the first part of the definition of Group B.

DMB only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see Cache maintenance instructions on page D3-1700. It has no effect on the ordering of any other instructions executing on the PE. A DMB intended to ensure the completion of cache maintenance operations must have an access type of both loads and stores.

See also Memory barriers on page D3-1722.

Data Synchronization Barrier (DSB)

The DSB instruction is a special memory barrier, that synchronizes the execution stream with memory accesses.

The DSB instruction takes the required shareability domain and required access types as arguments:

DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);

See Shareability and access limitations on the data barrier operations on page E2-2449.

If the required shareability is Full system then the operation applies to all observers within the system.

A DSB behaves as a DMB with the same arguments, and also has the additional properties defined in this section. The PE that executes the DSB instruction is referred to as the executing PE, PEe.

A DSB completes when all of the following apply:

- All explicit memory accesses that are observed by PEe before the DSB is executed and are of the required access types, and are from observers in the same required shareability domain as PEe, are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, all cache and branch predictor maintenance instructions issued by PEe before the DSB are complete for the required shareability domain.
- If the required access types of the DSB is reads and writes, all TLB maintenance instructions issued by PEe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can execute until the DSB completes.

A DSB intended to ensure the completion of cache maintenance operations must have an access type of both loads and stores.
See also *Memory barriers* on page G3-4058.

**Shareability and access limitations on the data barrier operations**

The `DMB` and `DSB` instructions can each take an optional limitation argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.
- The accesses for which the instruction operates. This is one of:
  - Read and write accesses in Group A and Group B.
  - Write accesses only in Group A and Group B.
  - Read access only in Group A and read and write accesses in Group B.

**Note**

This is occasionally referred to as a Load-Load/Store barrier.

If no specifiers are used then each instruction operates for read and write accesses, over the full system. See the instruction descriptions for more information about these arguments.

**Note**

`ISB` also supports an optional limitation argument that can only contain one value that corresponds to full system operation.

**Load-Acquire, Store-Release**

ARMv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

For all memory types, these instructions have the following ordering requirements:

- A Store-Release followed by a Load-Acquire is observed in program order by each observer within the shareability domain of the memory address being accessed by the Store-Release and the memory address being accessed by the Load-Acquire.
- For a Load-Acquire, observers in the shareability domain of the address accessed by the Load-Acquire observe accesses in the following order:
  1. The read caused by the Load-Acquire.
  2. Reads and writes caused by loads and stores that appear in program order after the Load-Acquire for which the shareability of the address accessed by the load or store requires that the observer observes the access.

There are no other ordering requirements on loads or stores that appear before the Load-Acquire.

- For a Store-Release, observers in the shareability domain of the address accessed by the Store-Release observe accesses in the following order:
  1. All of the following for which the shareability of the address accessed requires that the observer observes the access:
     - Reads and writes caused by loads and stores that appear in program order before the Store-Release.
     - Writes that were observed by the PE executing the Store-Release before it executed the Store-Release.
  2. The write caused by the Store-Release.

There are no other ordering requirements on loads or stores that appear in program order after the Store-Release.
• All Store-Release instructions must be multi-copy atomic when they are observed with Load-Acquire instructions.

In addition, for Device memory, these instructions have the following requirements:

• A Load-Acquire to an address in a memory-mapped peripheral of arbitrary system defined size using Device memory types will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.

• A Store-Release to an address in a memory-mapped peripheral of arbitrary system defined size using Device memory types will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.

• A memory access to a memory-mapped peripheral of arbitrary system defined size, using Device memory types that are architecturally required to be ordered before the memory access of the Store-Release, will arrive at the memory-mapped peripheral before any memory access to the same memory-mapped peripheral using Device memory types that are architecturally required to be ordered after the memory access of a Load-Acquire to the same memory location as the Store-Release, where the Load-Acquire has observed the value stored by the Store-Release.

Load-Acquire and Store-Release, other than LDAEXD and STLEXD, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

LDAEXD and STLEXD access two data elements. The address supplied to the instructions must be doubleword aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

--- Note ---

• Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties that apply to the Load-Exclusive or Store-Exclusive instructions also apply to the Load-Acquire Exclusive or Store-Release Exclusive instructions.

• The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.

---

### E2.7.4 Summary of the memory ordering rules

The following is a concise list of the situations that are required, by the ARM architecture specification, to cause externally-visible order of memory. This ordering means that if memory transaction A has externally visible order ahead of memory transaction B, then all observers within the shareability domains of A and B will observe A before B. See Terms used in the summary of the memory ordering rules on page E2-2451 for definitions of the terms used.

--- Note ---

This list applies to both AArch32 state and AArch64 state, and is consistent with the requirements of ARMv7.

---

1. **DMB** and **DSB** barrier instructions, and load acquire/store release instructions, create externally-visible order as defined by those instructions.

2. A True or False Address dependency from a Load to a Load or from a Load to a Store creates externally-visible order.

3. A True Control dependency from a Load to an **ISB** instruction creates externally-visible order between the load and any memory accesses after the **ISB** instruction.

4. A True Register data dependency from a Load to a Store creates externally-visible order.
5. A True Control dependency from a Load to a Store creates externally-visible order.

6. Memory is coherent within the shareability domain of a memory location, which means there is a total order of all writes to that location that all observers within that shareability domain will agree on.

    **Note**
    A consequence of this is that reads to the same location by the same processor are observed in order.

7. A Dependency from a Store to a Load through memory between different PEs creates externally-visible order but stores are not multi-copy atomic except where explicitly defined to be by the definition of the store.

    **Note**
    A consequence of the lack of multi-copy atomicity is that a Store to Load dependency through memory on the same PE does not create externally-visible order.

No other effects are required to create externally visible order in the ARM architecture.

**Terms used in the summary of the memory ordering rules**

The summary uses the following terms:

**Register data dependency**
This is defined in *Address dependencies and order on page E2-2446*.

**False Register data dependency**
A False Register data dependency is a Register data dependency where no register in the system holds a variable for which a change of the first data value causes a change of the second data value.

**True Register data dependency**
A True Register data dependency is a Register data dependency that is not a false Register data dependency.

**True Address dependency**
A True Address dependency between a load and a subsequent memory transaction exists where there is a True Register data dependency between the data value returned from the load and the address used by the subsequent memory transaction.

**False Address dependency**
A False Address dependency between a load and a subsequent memory transaction exists where there is a False Register data dependency between the data value returned from the load and the address used by the subsequent memory transaction.

**True Control dependency**
A True Control dependency between a load and a subsequent instruction exists:

- Where there is a True Register data dependency between the data value returned from the load and data value used in the evaluation of a conditional branch and the subsequent instruction is only executed as a result of one of the possible outcomes of that conditional branch.
- Where there is a True Register data dependency between the data value returned from the load and the data value used in the evaluation of a subsequent instruction that is a conditional selection, move or computation for which both:
  - The condition is determined by the returned data value.
  - No input data value for the selection, move or computation has a register data dependency on the returned data value.
Dependency from a Store to a Load through memory

A Dependency from a Store to a Load through memory exists where the Store and Load are to the same physical address, and value returned by the Load is the value that was written by the Store, and could not be the value that was previously held in that memory location.
E2.8 Memory types and attributes

In ARMv8 the ordering of accesses for locations of memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory on page E2-2458.
- Memory access restrictions on page E2-2462.

E2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.

- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.

- Writes to a memory location with the Normal memory attribute that is Non-cacheable must reach the endpoint for that location in the memory system in finite time.

- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.

- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See Multi-register loads and stores that access Normal memory on page E2-2457.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.

- An instruction that generates a sequence of accesses as described in Atomicity in the ARM architecture on page E2-2440 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory on page E2-2454.
- Non-shareable Normal memory on page E2-2455.
- Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory on page E2-2455.
See also:

• Multi-register loads and stores that access Normal memory on page E2-2457.

• Atomicity in the ARM architecture on page E2-2440.

• Memory barriers on page E2-2446. For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.

• Concurrent modification and execution of instructions on page E2-2442.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is defined as one of:

• Inner Shareable.
• Outer Shareable.
• Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see Synchronization and coherency issues between data and instruction accesses on page E2-2432.

--- Note ---

• System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.

• This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

--- Shareable, Inner Shareable, and Outer Shareable Normal memory ---

The ARM architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

• Each observer is only a member of a single Inner Shareability domain.

• Each observer is only a member of a single Outer Shareability domain.

• All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

--- Note ---

• Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.

• The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.
The details of the use of the shareability attributes are system-specific. Example E2-1 shows how they might be used.

Example E2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for cacheable Normal memory regions:

- A region might be assigned a cache allocation hint.
- It is IMPLEMENTATION DEFINED whether the Write-Through Cacheable and Write-Back Cacheable attributes can have an additional attribute of Transient or Non-transient, see Transient cacheability attribute on page E2-2457.
A memory location can be marked as having different cacheability attributes, for example when using aliases in a virtual to physical address mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases see Mismatched memory attributes on page E2-2463.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

--- Note ---
Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the ARM architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the inner and the outer cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example E2-2, Example E2-3 on page E2-2457, and Example E2-4 on page E2-2457 describe the possible ways of implementing a system with three levels of cache, level 1 (L1) to level 3 (L3).

--- Note ---
- L1 cache is the level closest to the PE, see Memory hierarchy on page E2-2430.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

---

Example E2-2 Implementation with two inner and one outer cache levels
---

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.
Example E2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example E2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

• The Inner cacheability attribute applied to L1 cache.
• The Outer cacheability attribute applied to L2 and L3 cache.

Transient cacheability attribute

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient attribute is supported for cacheable Normal memory regions. If an implementation supports this attribute, the set of possible cacheability attributes for a Normal memory region becomes:

• Write-Through Cacheable, Non-transient.
• Write-Back Cacheable, Non-transient.
• Write-Through Cacheable, Transient.
• Write-Back Cacheable, Transient.
• Non-cacheable.

The cacheability attribute can be defined independently for the inner and outer levels of caching.

The transient attribute indicates that the benefit of caching is for a relatively short period. Therefore it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

Note

The architecture does not specify what is meant by a relatively short period.

The description of the MAIR0, MAIR1, HMAIR0, and HMAIR1 registers includes the assignment of the Transient attribute in an implementation that supports this option.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.
E2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for ARMv8 Device memory are:

- **Gathering** (Identified as G or nG, see Gathering on page E2-2460).
- **Reordering** (Identified as R or nR, see Reordering on page E2-2461).
- **Early Write Acknowledgement hint** (Identified as E or nE, see Early Write Acknowledgement on page E2-2461).

The ARMv8 Device memory types are:

- **Device-nGnRnE**
  - Device non-Gathering, non-Reordering, No Early write acknowledgement.
  - Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.
- **Device-nGnRE**
  - Device non-Gathering, non-Reordering, Early Write Acknowledgement.
  - Equivalent to the Device memory type in earlier versions of the architecture.
- **Device-nGRE**
  - Device non-Gathering, Reordering, Early Write Acknowledgement.
  - ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.
  - The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.
- **Device-GRE**
  - Device Gathering, Reordering, Early Write Acknowledgement.
  - ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.
  - The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Collectively these are referred to as any Device memory type. Going down the list, the memory types are described as getting weaker; conversely the going up the list the memory types are described as getting stronger.

--- Note ---

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.

- The architecture does not require an implementation to distinguish between each of these memory types and ARM recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

- Earlier versions of the ARM architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.
An exception to this applies:

— Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

Note

• An instruction that generates a sequence of accesses as described in Atomicity in the ARM architecture on page E2-2440 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, ARM strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

— Write speculation that is visible to other observers is prohibited for all memory types.

Note

• A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.

• If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed by all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.

• A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.

• Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.

• A memory location with any Device memory attribute cannot be allocated into a cache.

• Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.

• All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

Note

In the Non-secure EL1 translation regime in systems where HCR.TGE == 1 and HCR.DC == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of HSR.ISS.[24] to be 0.

Note

• Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

Note

This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

The memory types for Translation table walks cannot be defined as any Device memory type within the TCR. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR.PTW bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.
For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

**Gathering**

In the Device memory attribute:

- G Indicates that the location has the Gathering attribute.
- nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See [Multi-register loads and stores that access Device memory on page E2-2462](#).

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted. This applies if one memory access is in Group A and one memory access is in Group B. That is, gathering is not permitted between a memory access in Group A and a memory access in Group B if the two accesses are separated by a barrier that affects at least one of the accesses.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

---

**Note**

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses, for example if one access is in Group A and the other is in Group B.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.

- The ARM architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

---

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the Non-gathering attribute.

An implementation is not permitted to perform an access with the Non-gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.
Reordering

In the Device memory attribute:

R               Indicates that the location has the Reordering attribute.

nR              Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.
- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

Early Write Acknowledgement

In the Device memory attribute:

E               Indicates that the location has the Early Write Acknowledgement attribute.

nE              Indicates that the location has the No Early Write Acknowledgement attribute.

Early Write Acknowledgement is a hint to the platform memory system. Assigning the No Early Write Acknowledgement attribute to a Device memory location recommends that only the endpoint of the write access returns a write acknowledgement of the access, and that no earlier point in the memory system returns a write acknowledge. This means that a DSB barrier, executed by the PE that performed the write to the No Early Write Acknowledgement location, completes only after the write has reached its endpoint in the memory system. Typically, this endpoint is a peripheral or physical memory.

When the Early Write Acknowledgement attribute is assigned to a Device memory location, there is no such recommendation for the handling of accesses to that location.

Note

- The Early Write Acknowledgement hint has no effect on the ordering rules. The purpose of signaling no Early Write Acknowledgement is to signal to the interconnect that the peripheral requires the ability to signal the acknowledgement. The No Write Acknowledgement signal also provides an additional semantic that can be interpreted by the driver that is accessing the peripheral.
- This attribute is treated as a hint, as the exact nature of the interconnects attached to a PE is outside the scope of the ARM architecture definition, and not all interconnects provide a mechanism to ensure that a write has reached the physical endpoint of the memory system.
• ARM recommends that writes with the No Early Write Acknowledgement hint are used for PCIe configuration writes. However, the mechanisms by which PCIe configuration writes are identified are IMPLEMENTATION DEFINED.

• ARM strongly recommends that the Early Write Acknowledgement hint is not ignored by a PE, but is made available for use by the system.

Because the No Early Write Acknowledgement attribute is a hint:

• An implementation is permitted to perform an access with the Early Write Acknowledgement attribute in a manner consistent with the requirements specified by the No Early Write Acknowledgement attribute.

• An implementation is permitted to perform an access with the No Early Write Acknowledgement attribute in a manner consistent with the relaxations allowed by the Early Write Acknowledgement attribute.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load and store instructions.

For an LDRD, STRD, or LDM instruction with a register list that includes the PC, or an STM instruction with a register list that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not defined by the architecture.

For a VLDM, VSTM, LDM and STM instruction with a register list that does not include the PC, all registers are accessed in ascending address order for Device accesses with the non-Reordering attribute.

E2.8.3 Memory access restrictions

The following restrictions apply to memory accesses:

• For accesses to any two bytes, \( p \) and \( q \), that are generated by the same instruction:
  — The bytes \( p \) and \( q \) must have the same memory type and shareability attributes. otherwise the results are CONSTRUANED UNPREDICTABLE. For example, an LDC, LDM, LDRD STC, STM or STRD instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRUANED UNPREDICTABLE.
  — Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for bytes \( p \) and \( q \).

For the permitted CONSTRUANED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or shareability attributes on page J1-5371.

• The accesses of an instruction that causes multiple accesses to any type of Device memory must not cross a 4KB address boundary, otherwise the effect is CONSTRUANED UNPREDICTABLE. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.

  Note

This situation is CONSTRUANED UNPREDICTABLE even if the cause of the accesses is an unaligned access to any type of Device memory in an implementation that includes the Virtualization Extensions.

ARM expects this restriction to impose constraints on the placing of volatile memory devices in the memory map of a system, rather than expecting a compiler to be aware of the alignment of memory accesses.

For the permitted CONSTRUANED UNPREDICTABLE behavior, see Crossing a 4KB boundary with a Device access on page J1-5371.
E2.9 Mismatched memory attributes

In the ARMv8 architecture mismatched memory attributes are controlled by privileged software. For more information, see Chapter G4 The AArch32 Virtual Memory System Architecture.

Physical memory locations are accessed with mismatched attributes if all accesses to the location do not use a common definition of all of the following attributes of that location:

• Memory type, Device or Normal.
• Shareability.
• Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

--- Note ---

The terms location and memory location refer to any byte within the current coherency granule and are used interchangeably.

When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:

• Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
  — A read of the memory location by one agent might not return the value most recently written to that memory location by the same agent.
  — Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.
• There might be a loss of coherency when multiple agents attempt to access a memory location.
• There might be a loss of properties derived from the memory type, as described in later bullets in this section.
• If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
• Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

• Prohibition of speculative read accesses.
• Prohibition on Gathering.
• Prohibition on Re-ordering.

For the following situations, when a physical memory location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. If the only memory type mismatch associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.

2. Any agent that reads that memory location using the same common definition of the shareability and cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all of the following conditions are met:

   • All aliases to the memory location with write permission both use a common definition of the shareability and cacheability attributes for the memory location, and either:
     — Have the inner cacheability attribute the same as the outer cacheability attribute.
     — In the Non-secure EL1 translation regime, have HCR2.MIOCNCE set to 0.
   • All aliases to a memory location use a definition of the shareability attributes that encompasses all the agents with permission to access the location.
3. The possible software-visible effects caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
   • Any Device memory type.
   • Normal Inner Non-cacheable, Outer Non-cacheable memory.
In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   • Possible loss of properties derived from the memory type when multiple agents attempt to access the memory location.
   • Possible reordering of memory transactions to the same memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to the location, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable locations between agents in different shareability domains. This means:
   • Before writing to a location not using the Write-Back attribute, software must invalidate, or clean, a location from the caches if any agent might have written to the location with the Write-Back attribute. This avoids the possibility of overwriting the location with stale data.
   • After writing to a location with the Write-Back attribute, software must clean the location from the caches, to make the write visible to external memory.
   • Before reading the location with a cacheable attribute, software must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.

   ——— Note ———

   Cache maintenance instructions can only be accessed from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see Exception-generating and exception-handling instructions on page F1-2495. For information on cache maintenance instructions, see Cache support on page G3-4024.

   In all cases:
   • Location refers to any byte within the current coherency granule.
   • A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   • In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering of cache and branch predictor maintenance instructions on page G3-4040.

   ——— Note ———

   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different shareability attributes, then ordering and coherency are guaranteed only if:
   • Each PE that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.
• A DMB barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory location that use different attributes.

--- Note ---

The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.
E2.10 Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using synchronization primitives. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note
Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table E2-4 shows the synchronization primitives and the associated CLREX instruction.

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address \( x \) is:

- The Load-Exclusive instruction reads a value from memory address \( x \).
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address \( x \) only if no other observer, process, or thread has performed a more recent store to address \( x \). The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block on page E2-2471. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note
In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.
E2.10.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the Shareability attribute is Non-shareable, the exclusive access instructions rely on a local monitor that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:
- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state
- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  — If the store took place the status value is 0.
  — Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If the local monitor is in the Open Access state
- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:
- If the write is to a physical address that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

Figure E2-4 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

![Figure E2-4 Local monitor state machine diagram](image-url)
For more information about marking see *Marking and the size of the marked memory block on page E2-2471.*

Note
---

For the local monitor state machine, as shown in Figure E2-4 on page E2-2467:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

**Changes to the local monitor state resulting from speculative execution**

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure E2-4 on page E2-2467.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure E2-4 on page E2-2467.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure E2-4 on page E2-2467 must not indefinitely delay forward progress of execution.

**E2.10.2 Exclusive access instructions and Shareable memory locations**

For memory locations that have the Shareable attribute, exclusive access instructions rely on:

- A local monitor for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations on page E2-2467*, except that for Shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

  The local monitor can ignore accesses from other PEs in the system.

- A global monitor that marks a physical address as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

Note
---

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2472.*
--- Note ---
The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

--- Note ---
For Shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:
- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

--- Note ---
To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.

- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.

The set of memory types that support atomic instructions must include all of the memory types for which a global monitor is implemented.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an external abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault Status code of:
  - DFSR.STATUS = 0b110101 when using the Long-descriptor translation table format. The fault can also be reported in the HSR.ISS[5:0] field for exceptions to Hyp mode.
  - DFSR.FS = 0b10101 when using the Short-descriptor translation table format.
  The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an ARM PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
• Some memory types.

**Operation of the global monitor**

A Load-Exclusive instruction from Shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

--- **Note** ---

The global monitor only supports a single outstanding exclusive access to Shareable memory for each PE.

---

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

• The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  — A status value of 0 is returned to a register to acknowledge the successful store.
  — The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  — If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.

• If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  — A status value of 1 is returned to a register to indicate that the store failed.
  — The global monitor is not affected and remains in Open Access state for the requesting PE.

• If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  — If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  — If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to Shareable memory by PE(n) can respond to all the Shareable memory accesses visible to it. This means it responds to:

• Accesses generated by PE(n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

**Clear global monitor event**

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see **Wait For Event and Send Event on page G1-3906**.

**Figure E2-5 on page E2-2471** shows the state machine for PE(n) in a global monitor.
Note

For the global monitor state machine, as shown in Figure E2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.

- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked Shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure E2-5 only shows how the operations by (\( n \)) cause state transitions of the state machine for PE(n).

- A Load-Exclusive instruction can only update the marked Shareable memory address for the PE issuing the Load-Exclusive instruction.

- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

---

### E2.10.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size \( 2^a \) is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. For example, in an implementation where \( a = 4 \), a successful LDRXB of address \( 0x341B4 \) defines a marked block using bits[47:4] of the address. This means that the four words of memory from \( 0x341B0 \) to \( 0x341BF \) are marked for exclusive access.
The size of the marked memory block is called the **Exclusives Reservation Granule**. The Exclusives Reservation Granule is **IMPLEMENTATION DEFINED** in the range 2 - 512 words:

- 3 words in an implementation where \( a = 4 \).
- 512 words in an implementation where \( a = 11 \).

In some implementations the CTR identifies the Exclusives Reservation Granule, see CTR. Otherwise, software must assume that the maximum Exclusives Reservation Granule, 512 words, is implemented.

### E2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a **CLREX** instruction as part of a context switch is not required in most situations.

---

**Note**

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

---

### E2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a **LDREX/STREX** pair or a **LDREXB/STREXB** pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

The following notes describe use of a Load-Exclusive/Store-Exclusive pair, `LoadExcl/StoreExcl`, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in **Table E2-4 on page E2-2466**:

- The exclusives support a single outstanding exclusive access for each software thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target virtual address of a `StoreExcl` is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be **UNPREDICTABLE**. As a result, a `LoadExcl/StoreExcl` pair can only be relied upon to eventually succeed if the `LoadExcl` and the `StoreExcl` are executed with the same virtual address.

- If two `StoreExcl` instructions are executed without an intervening `LoadExcl` instruction the second `StoreExcl` instruction returns a status value of 1. This means that:
  - ARM recommends that, in a given thread of execution, every `StoreExcl` instruction has a preceding `LoadExcl` instruction associated with it.

  It is not necessary for every `LoadExcl` instruction to have a subsequent `StoreExcl` instruction.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a Store-Exclusive instruction is the same as the transaction size of the preceding Load-Exclusive instruction executed in that thread. If the transaction size of a Store-Exclusive instruction is different from the preceding Load-Exclusive instruction in the same thread of execution, behavior can be **UNPREDICTABLE**. As a result, software can rely on a `LoadExcl/StoreExcl` pair to eventually succeed only if they have the same size.

- An implementation might clear an exclusive monitor between the `LoadExcl` instruction and the `StoreExcl`, instruction without any application-related cause. For example, this might happen because of cache evictions. Software must, in any single thread of execution, avoid having any explicit memory accesses, system control register updates, or cache maintenance instructions between the `LoadExcl` instruction and the associated `StoreExcl` instruction.

- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.
• The architecture sets an upper limit of 2048 bytes on the exclusive reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule. This is a performance guideline rather than a functional requirement.

• After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN.

• For the memory location accessed by a LoadExcl/StoreExcl pair, if the memory attributes for the LoadExcl instruction differ from the memory attributes for the StoreExcl instruction, behavior is UNPREDICTABLE. This can occur either:
  — Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  — As a result of using different virtual addresses, with different attributes, that point to the same physical address. This case is covered by another bullet point in this list.

• The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is UNPREDICTABLE. The instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

  — **Note**
  
  ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

• If the mapping of the virtual to physical address is changed between the LDREX instruction and the STREX instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when updating translation table entries on page G4-4136, if the STREX is performed after another write to the same physical address as the STREX, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the STREX will not pass its monitor check.

  — **Note**
  
  ARM expects that, in many implementations, either:
  — The TLB invalidation will clear either the local or global monitor.
  — The physical address will be checked between the LDREX and STREX.

  — **Note**
  
  In the event of repeatedly-contending Load-Exclusive/Store-Exclusive instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

### E2.10.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in Wait For Event and Send Event on page G1-3906. However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

  — **Note**
  
  This is equivalent to issuing an SEV instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.
E2 The AArch32 Application Level Memory Model
E2.10 Synchronization and semaphores
Part F
The AArch32 Instruction Sets
Chapter F1
The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- Support for instructions in different versions of the ARM architecture on page F1-2478.
- Unified Assembler Language on page F1-2479.
- Branch instructions on page F1-2481.
- Data-processing instructions on page F1-2482.
- PSTATE and banked register access instructions on page F1-2490.
- Load/store instructions on page F1-2491.
- Load/store multiple instructions on page F1-2493.
- Miscellaneous instructions on page F1-2494.
- Exception-generating and exception-handling instructions on page F1-2495.
- Coprocessor instructions on page F1-2496.
- Advanced SIMD and floating-point load/store instructions on page F1-2497.
- Advanced SIMD and floating-point register transfer instructions on page F1-2499.
- Advanced SIMD data-processing instructions on page F1-2500.
- Floating-point data-processing instructions on page F1-2508.
F1.1 Support for instructions in different versions of the ARM architecture

This manual describes the ARM AArch32 instruction sets, T32 and A32, for the ARMv8 architecture. Therefore, it indicates how any options or extensions in the ARMv8 architecture affect the available instructions. Also, Chapter F6 ARMv8 Changes to the T32 and A32 Instruction Sets provides information for those migrating from earlier versions of the architecture.

This manual does not provide any information about which T32 and A32 instructions were supported in specific earlier versions of the architecture. For this information, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.
F1.2 Unified Assembler Language

This manual uses the ARM Unified Assembler Language (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier ARM assembly language mnemonics are still supported as synonyms, as described in the instruction details.

--- Note ---

Most earlier T32 assembly language mnemonics are not supported.

---

UAL includes instruction selection rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an ADD R0, R1, R2 instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F1.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, ARM recommends that:

- IT instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any IT instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an IT instruction must be written with a condition. These conditions must match the conditions imposed by the IT instruction. For example, an IT TTEE EQ instruction imposes the EQ condition on the first two following instructions, and the NE condition on the next two. Those four instructions must be written with EQ, EQ, NE and NE conditions respectively.

Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a condition code field cannot be made conditional by an IT instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a condition code field.

F1.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the PC or Align(PC, 4) value of the instruction. The PC value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The Align(PC, 4) value of an instruction is its PC value ANDed with 0xFFFFFFFC to force it to be word-aligned. There is no difference between the PC and Align(PC, 4) values for an A32 instruction, but there can be for a T32 instruction.
2. Calculate the offset from the PC or Align(PC, 4) value of the instruction to the address of the labeled instruction or literal data item.
3. Assemble a PC-relative encoding of the instruction, that is, one that reads its PC or Align(PC, 4) value and adds the calculated offset to form the required address.
For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- B, BL, and BLX (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch.

- CBNZ and CBZ. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch. They do not support backward branches.

- LDC, LDC2, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

  When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the Align(PC, 4) value of the instruction. Encodings that subtract 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

  There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by [PC, #<imm>], where:

  - +/- Is + or omitted to specify that the immediate offset is to be added to the Align(PC, 4) value, or - if it is to be subtracted.
  - <imm> Is the immediate offset.

  This alternative syntax makes it possible to assemble the encodings that subtract 0 from the Align(PC, 4) value, and to disassemble them to a syntax that can be re-assembled correctly.

- ADR. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

  When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the Align(PC, 4) value of the instruction. The encoding that subtracts 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

  There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions ADD <Rd>, PC, #<imm> or subtractions SUB <Rd>, PC, #<imm>. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the Align(PC, 4) value, and to disassemble it to a syntax that can be re-assembled correctly.

**Note**

ARM recommends that where possible, software avoids using:

- The alternative syntax for the ADR, LDC, LDC2, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR instructions.

- The encodings of these instructions that subtract 0 from the Align(PC, 4) value.
F1.3 Branch instructions

Table F1-1 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

<table>
<thead>
<tr>
<th>Instruction</th>

</tr>
</tbody>
</table>

a. These instructions do not exist in the A32 instruction set.
b. The range is determined by the instruction set of the $BLX$ instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by $LDR$, $LDM$ and data-processing instructions. For details see $Load/store instructions$ on page F1-2491, $Load/store multiple instructions$ on page F1-2493, $Standard data-processing instructions$ on page F1-2482, and $Shift instructions$ on page F1-2484.

In addition to the branch instructions shown in Table F1-1:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see $Data-processing instructions$ on page F1-2482.
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see $Load/store instructions$ on page F1-2491.
F1.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- **Standard data-processing instructions.**
  These instructions perform basic data-processing operations, and share a common format with some variations.
- **Shift instructions** on page F1-2484.
- **Multiply instructions** on page F1-2484.
- **Saturating instructions** on page F1-2486.
- **Saturating addition and subtraction instructions** on page F1-2486.
- **Packing and unpacking instructions** on page F1-2487.
- **Parallel addition and subtraction instructions** on page F1-2488.
- **Divide instructions** on page F1-2489.
- **Miscellaneous data-processing instructions** on page F1-2489.

For related Advanced SIMD and floating-point instructions see *Advanced SIMD data-processing instructions* on page F1-2500 and *Floating-point data-processing instructions* on page F1-2508.

F1.4.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- **A modified immediate constant** that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see *Modified immediate constants in T32 instructions* on page F3-2540 and *Modified immediate constants in A32 instructions* on page F4-2569.

If the second operand is another register, it can optionally be shifted in any of the following ways:

- **LSL** Logical Shift Left by 1-31 bits.
- **LSR** Logical Shift Right by 1-32 bits.
- **ASR** Arithmetic Shift Right by 1-32 bits.
- **ROR** Rotate Right by 1-31 bits.
- **RRX** Rotate Right with Extend. For details see *Shift and rotate operations* on page E1-2380.

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than **CMN**, **CMP**, **TEQ**, and **TST**, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the **ADD** and **MOV** instructions.

These instructions can optionally set the condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table F1-2 on page F1-2483 summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in Chapter F2 About the T32 and A32 Instruction Descriptions, one section for each of the following:

- **INSTRUCTION (immediate)** where the second operand is a modified immediate constant.
- **INSTRUCTION (register)** where the second operand is a register, or a register shifted by a constant.
- **INSTRUCTION (register-shifted register)** where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

F1.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- Table F1-4 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.
  The least significant 32 bits of the result are used. More significant bits are discarded.

- Table F1-5 on page F1-2485 summarizes the signed multiply instructions.

- Table F1-6 on page F1-2485 summarizes the unsigned multiply instructions.

## F1.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

- **S** Signed arithmetic modulo 2^8 or 2^16.
- **Q** Signed saturating arithmetic.
- **SH** Signed arithmetic, halving the results.
- **U** Unsigned arithmetic modulo 2^8 or 2^16.
- **UQ** Unsigned saturating arithmetic.
- **UH** Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

- **ADD16** Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.
- **ASX** Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.
- **SAX** Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.
- **SUB16** Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.
- **ADD8** Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.
- **SUB8** Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table F1-10 shows.

See also Advanced SIMD parallel addition and subtraction on page F1-2501.

F1.4.8 Divide instructions

In ARMv8, signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set. For more information about their implementation in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

For descriptions of the instructions see:
- *SDIV* on page F7-3019.
- *UDIV* on page F7-3202.

For the SDIV and UDIV instructions, divide-by-zero always returns a zero result.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of 0b0010 indicates they are implemented in both the T32 and A32 instruction sets.

F1.4.9 Miscellaneous data-processing instructions

Table F1-11 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

**Table F1-11 Miscellaneous data-processing instructions**

F1.5 PSTATE and banked register access instructions

These instructions transfer PE state information to or from a general-purpose register.

F1.5.1 PSTATE access instructions

PSTATE holds process state information, see Process state, PSTATE on page E1-2387. In AArch32 state:

- At EL1 or higher, PSTATE is accessible using the Current Program Status Register (CPSR).
- At EL0, a subset of the CPSR is accessible as the Application Program Status Register (APSR).
- On taking an exception, the contents of the CPSR are copied to the Saved Program Status Register (SPSR) of the mode from which the exception is taken.

The MRS and MSR instructions move the contents of the CPSR, APSR, or the SPSR of the current mode to or from a general-purpose register, see:

- MRS on page F7-2892.
- MSR (immediate) on page F7-2900.
- MSR (register) on page F7-2902.

When executed at EL0, MRS and MSR instructions can only access the APSR.

The PSTATE condition flags, PSTATE.{N, Z, C, V} are set by the execution of data-processing instructions, and can control the execution of conditional instructions. However, software can set the condition flags explicitly using the MSR instruction, and can read the current state of the condition flags explicitly using the MRS instruction.

In addition, at EL1 or higher, software can use the CPS instruction to change the PSTATE.M field and the PSTATE.{A, I, F} interrupt mask bits, see CPS, CPSID, CPSIE on page F7-2720.

F1.5.2 Banked register access instructions

At EL1 or higher, the MRS (Banked register) and MSR (Banked register) instructions move the contents of a Banked general-purpose register, the SPSR, or the ELR_hyp, to or from a general-purpose register. See:

- MRS (Banked register) on page F7-2894.
- MSR (Banked register) on page F7-2897.
F1.6 Load/store instructions

Table F1-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:
• Load/store multiple instructions on page F1-2493.
• Advanced SIMD and floating-point load/store instructions on page F1-2497.

Load/store instructions have several options for addressing memory. For more information, see Addressing modes on page F1-2492.

F1.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

F1.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

F1.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an LDRT instruction executes in exactly the way that the equivalent LDR instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

Note

As described in Execution privilege, Exception levels, and AArch32 Privilege levels on page G4-4060, execution at PL1 describes all of the following:
• Execution at Non-secure EL1 using AArch32.
F1 The AArch32 Instruction Sets Overview
F1.6 Load/store instructions

- Execution at Secure EL1 using AArch32 when EL3 is not implemented.
- Execution at Secure EL1 using AArch32 when EL3 is implemented and is using AArch64.
- Execution at Secure EL3 when EL3 is implemented and is using AArch32.

The Load unprivileged and Store unprivileged instructions are UNPREDICTABLE if executed at EL2.

For more information, see Access permissions on page G4-4111.

F1.6.4 Load-Exclusives and Store-Exclusives

Load-Exclusive and Store-Exclusives provide shared memory synchronization. For more information, see Synchronization and semaphores on page E2-2466.

F1.6.5 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code. Instructions marked (literal) in their title in Chapter F2 About the T32 and A32 Instruction Descriptions are PC-relative loads.

The offset takes one of three formats:

- **Immediate**
  The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers.

- **Register**
  The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

- **Scaled register**
  The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

- **Offset**
  The offset is added to or subtracted from the base register to form the memory address.

- **Pre-indexed**
  The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.

- **Post-indexed**
  The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

--- Note ---

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter F2 About the T32 and A32 Instruction Descriptions for full details for each instruction.
F1.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC. Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F1-13 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

When executing at EL1, variants of the LDM and STM instructions load and store User mode registers. Another system level variant of the LDM instruction performs an exception return.

F1.7.1 Loads to the PC

The LDM, LDMDA, LDMDB, LDME, and POP instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

</tr>
<tr>
<td>Yield</td>
<td>YIELD on page F7-3264</td>
</tr>
</tbody>
</table>

F1.8.1    The Yield instruction

In a Symmetric Multi-Threaded (SMT) design, a thread can use the YIELD instruction to give a hint to the PE that it is running on. The YIELD hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

AArch32 state defines a YIELD instruction as a specific NOP (No Operation) hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.
F1.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see Supervisor Call (SVC) exception on page G1-3879.

- The Breakpoint instruction BKPT provides software breakpoints. For more information, see Software Breakpoint Instruction exceptions on page G2-3967.

- In an implementation that includes EL3, when executing at EL1 or higher, the SMC instruction generates a Secure Monitor Call exception. For more information, see Secure Monitor Call (SMC) exception on page G1-3882.

- In an implementation that includes EL2, in software executing in a Non-secure EL1 mode, the HVC instruction generates a Hypervisor Call exception. For more information, see Hypervisor Call (HVC) exception on page G1-3883.

For an exception taken to an EL1 mode:

- The system level variants of the SUB and LDM instructions can perform a return from an exception.

  Note
  The variants of SUB include MOVS. See the references to SUB PC, LR in Table F1-15 for more information.

- The SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see Exception return to an Exception level using AArch32 on page G1-3860.

Table F1-15 summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

<table>

</tr>
</tbody>
</table>

\(^a\) The A32 instruction set includes other instruction forms that can be used for an exception return, that have previously been described as variants of SUB PC, LR. ARM deprecates any use of these instruction forms.
F1.10 Coprocessor instructions

There are three types of instruction for communicating with conceptual coprocessors. These permit the PE to:

- Initiate a coprocessor data-processing operation. For details see *CDP, CDP2* on page F7-2705.

- Transfer general-purpose registers to and from coprocessor registers. For details, see:
  - *MCR, MCR2* on page F7-2864.
  - *MCRR, MCRR2* on page F7-2866.
  - *MRC, MRC2* on page F7-2887.
  - *MRRC, MRRC2* on page F7-2890.

- Load or store the values of coprocessor registers. For details, see:
  - *LDC, LDC2 (immediate)* on page F7-2764.
  - *LDC, LDC2 (literal)* on page F7-2768.
  - *STC, STC2* on page F7-3087.

The instruction set encodings provide support for up to 16 coprocessors, CP0 to CP15, with a 4-bit field in each coprocessor instruction to identify the coprocessor number. In ARMv8 the only supported coprocessors are CP10, CP11, CP14, and CP15, and these are supported only in AArch32 state.

--- Note ---

Multiple coprocessors can be used together to provide a larger block of coprocessor instructions. CP10 and CP11 are used in this way.

---

CP10 and CP11 are used, together, for floating-point and some Advanced SIMD functionality. There are different instructions for accessing these coprocessors, of similar types to the instructions for CP14 and CP15, that is to:

- Initiate a coprocessor data-processing operation, see *Floating-point data-processing instructions* on page F1-2508.

- Transfer general-purpose registers to and from coprocessor registers, see *Advanced SIMD and floating-point register transfer instructions* on page F1-2499.

- Load or store the values of coprocessor registers, see *Advanced SIMD and floating-point load/store instructions* on page F1-2497.

Coprocessor instructions are part of the instruction stream executed by the PE. Any coprocessor instruction that cannot be executed by the implemented conceptual coprocessors causes an Undefined Instruction exception. This means that, in ARMv8 AArch32 state, all coprocessor access instruction encodings for coprocessors other than CP10, CP11, CP14, and CP15 are unallocated.
F1.11 Advanced SIMD and floating-point load/store instructions

Table F1-16 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see Element and structure load/store instructions.

Table F1-16 SIMD and floating-point register file load/store instructions

F1.11.1 Element and structure load/store instructions

Table F1-17 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see Figure F1-1 on page F1-2498 for an example of de-interleaving. Interleaving is the inverse process.

</table>

\textbf{Figure F1-1} shows the de-interleaving of a \textit{VLD3.16} (multiple 3-element structures) instruction:

\textbf{Figure F1-1} De-interleaving an array of 3-element structures

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, \textit{VLD4} and \textit{VST4} instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.
## F1.12 Advanced SIMD and floating-point register transfer instructions

Table F1-18 summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details see The SIMD and floating-point register file on page E1-2393.

F1.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure F1-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

--- Note ---

Figure F1-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with one, two, eight, or sixteen operations performed in parallel instead of four.

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure F1-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure F1-4 on page F1-2501 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.
Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the ARM standard floating-point arithmetic defined in "Floating-point and Advanced SIMD support on page A1-48."

### F1.13.1 Advanced SIMD parallel addition and subtraction

Table F1-19 shows the Advanced SIMD parallel add and subtract instructions.

</table>

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over \{0, 1\}. \textbf{VMUL} and \textbf{VMULL} are the only instructions that operate on polynomials. \textbf{VMULL} produces a 16-bit polynomial over \{0, 1\}.
- Single-precision (32-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

F1 The AArch32 Instruction Sets Overview
F1.14 Floating-point data-processing instructions
Chapter F2
About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• *Format of instruction descriptions* on page F2-2512.
• *Standard assembler syntax fields* on page F2-2516.
• *Conditional execution* on page F2-2517.
• *Shifts applied to a register* on page F2-2520.
• *Memory accesses* on page F2-2523.
• *Encoding of lists of general-purpose registers and the PC* on page F2-2524.
• *Additional pseudocode support for instruction descriptions* on page F2-2525.
F2.1 Format of instruction descriptions

The instruction descriptions in Chapter F7 T32 and A32 Base Instruction Set Instruction Descriptions and Chapter F8 T32 and A32 Advanced SIMD and floating-point Instruction Descriptions normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- A description of each encoding of the instruction.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Notes, if applicable.

Each of these items is described in more detail in the following subsections.

F2.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

F2.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F2.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labelled as:

- A1, A2, A3 … for the first, second, third and any additional A32 encodings.
- T1, T2, T3 … for the first, second, third and any additional T32 encodings.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. In some cases, multiple syntax variants are given. These are written in a typewriter font using the conventions described in Assembler syntax prototype line conventions on page F2-2514. The correct one to use can be indicated by:
  - A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading Flag setting, rotate right with extend variant in the description of the A1 encoding of the ADC, ADCS (register) instructions in A1 on page F7-2637.
  - An annotation to the syntax, such as Inside IT block or Outside IT block. See, for example, the syntax descriptions of the T1 encoding of the ADC, ADCS (register) instructions in T1 on page F7-2638.

In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax AND R0, R0, R8 ensures selection of a 32-bit encoding but AND R0, R0, R1 selects a 16-bit encoding.
For each instruction encoding belonging to a target instruction set, an assembler can use this information to
determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple
encodings can encode the instruction then:

— If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture prefers the
16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit
encoding.

Software can use the .W and .N qualifiers to specify the required encoding width, see Standard
assembler syntax fields on page F2-2516.

— If multiple encodings of the same length can encode the instruction, the Assembler syntax subsection
says which encoding is preferred, and how software can, instead, select the other encodings.

Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally
the assembler generates an error saying that the instruction is not available in that instruction set.

Note

In some cases, an instruction is available in one instruction set but not in another. The Assembler syntax
subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == 0b1111
described in Unconditional instructions on page F4-2585 cannot have a condition code, but the equivalent
T32 instructions often can, and this usually appears in the Assembler syntax subsection as a statement that
the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether
an instruction is available in a given instruction set is whether there is an available encoding for it in that
instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that
encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the
operand combination, in order to produce more readable disassembled code.

• An encoding diagram. This is half-width for 16-bit T32 encodings and full-width for 32-bit T32 and A32
encodings. The 32-bit A32 encoding diagrams number the bits from 31 to 0, while the 32-bit T32 encoding
diagrams number the bits from 15 to 0 for each halfword, to distinguish them from A32 encodings and to act
as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.

In particular, if instructions are stored using the standard little-endian instruction endianness, the encoding
diagram for an A32 instruction at address A shows the bytes at addresses A+3, A+2, A+1, A from left to right,
but the encoding diagram for a 32-bit T32 instruction shows them in the order A+1, A for the first halfword,
followed by A+3, A+2 for the second halfword.

• Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields
into inputs to the encoding-independent pseudocode in the Operation subsection, and that picks out any
special cases in the encoding. For a detailed description of the pseudocode used and of the relationship
between the encoding diagram, the encoding-specific pseudocode and the encoding-independent
pseudocode, see Appendix J9 ARM Pseudocode Definition.

F2.1.4 Assembler symbols

The Assembly symbols describes the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

• Descriptions of all of the variable or optional fields of the syntax.

Some syntax fields are standardized across all or most instructions. Standard assembler syntax fields on
page F2-2516 describes these fields.
By default, syntax fields that specify registers, such as <Rd>, <Rn>, or <Rt>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as d, n, or t) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

— Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.
— In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is only available if <Rd> and <Rn> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

* Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. ARM recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

**Assembler syntax prototype line conventions**

The following conventions are used in assembler syntax prototype lines and their subfields:

< > Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as add = TdUE. The assembler must only use encodings that produce that output.

{ } Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

# In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

- Must treat the # as optional where an instruction syntax description shows it as optional.
- Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

--- Note ---

ARM recommends that UAL assemblers treat all uses of # shown in this manual as optional.

spaces Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

+/- This indicates an optional + or - sign. If neither is coded, + is assumed.
All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

F2.1.5 Pseudocode describing how the instruction operates

The Operation for all classes subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix J9 ARM Pseudocode Definition.
F2.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

<

Is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F2-2517 for the range of available conditions and their encoding. If < is omitted, it defaults to always (AL).

>

Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

.N Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

.W Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description. The assembler syntax includes a mandatory .W qualifier, along with a note describing the cases in which it applies, where this qualifier is required to select a particular encoding for an instruction. Additional assembler syntax will describe the syntax when the conditions are not met.

Note

When assembling to the A32 instruction set, the .N qualifier produces an assembler error and the .W qualifier has no effect.
F2.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR condition flags. Table F2-1 lists the available conditions.

Table F2-1 Condition codes

<table>
<thead>
<tr>
<th>cond</th>
<th>Mnemonic extension</th>
<th>Meaning (integer)</th>
<th>Meaning (floating-point) a</th>
<th>Condition flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>

<td>Signed less than or equal</td>
<td>Less than, equal, or unordered</td>
<td>Z == 1 or N != V</td>
</tr>
<tr>
<td>1110</td>
<td>None (AL) d</td>
<td>Always (unconditional)</td>
<td>Always (unconditional)</td>
<td>Any</td>
</tr>
</tbody>
</table>

a. Unordered means at least one NaN operand.
b. HS (unsigned higher or same) is a synonym for CS.
c. LO (unsigned lower) is a synonym for CC.
d. AL is an optional mnemonic extension for always, except in IT instructions. For details see IT on page F7-2750.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information see Conditional instructions on page F1-2479 and IT on page F7-2750. Some conditional branch instructions do not require a preceding IT instruction, because they include a condition code in their encoding.

In A32 instructions, bits[31:28] of the instruction contain the condition code, or contain 0b1111 for some A32 instructions that can only be executed unconditionally.

ARM deprecates the conditional execution of any instruction encoding provided by Advanced SIMD that is not also provided by floating-point, and strongly recommends that:

* For A32 instructions, any such Advanced SIMD instruction that can be conditionally executed is executed with the <c> field omitted or set to AL.

** Note **

This applies only to VDUP, see VDUP (general-purpose register) on page F8-3432. The other A32 instructions do not permit conditional execution.
• For T32 instructions, such Advanced SIMD instructions are never included in an IT block. This means they must be specified with the `<c>` field omitted or set to AL.

This deprecation does not apply to Advanced SIMD instruction encodings that are also available as floating-point instruction encodings. That is, it does not apply to the Advanced SIMD encodings of the instructions described in the following sections:

• $VLD M, VLD M D B, VLD M I A$ on page F8-3492.
• $VLDR$ on page F8-3496.
• $VMOV$ (general-purpose register to scalar) on page F8-3546.
• $VMOV$ (between two general-purpose registers and a doubleword floating-point register) on page F8-3537.
• $VMRS$ on page F8-3558.
• $VMSR$ on page F8-3560.
• $VPOP$ on page F8-3612.
• $VPUSH$ on page F8-3614.
• $VSTM, VSTM DB, VSTM IA$ on page F8-3771.
• $VSTR$ on page F8-3775.

See also Conditional execution of undefined instructions on page G1-3877.

F2.3.1 Pseudocode description of conditional execution

The $CurrentCond()$ pseudocode function has prototype:

```
bids(4) AArch32.CurrentCond();
```

This function returns a 4-bit condition specifier as follows:

• For A32 instructions, it returns bits[31:28] of the instruction.
• For the T1 and T3 encodings of the Branch instruction (see $B$ on page F7-2681), it returns the 4-bit cond field of the encoding.
• For all other T32 instructions:
  — If $PSTATE.IT<3:0> != '0000'$ it returns $PSTATE.IT<7:4>$.
  — If $PSTATE.IT<7:0> == '00000000'$ it returns '1110'.
  — Otherwise, execution of the instruction is UNPREDICTABLE.

For more information, see Process state, $PSTATE$ on page E1-2387.

The $ConditionPassed()$ function uses this condition specifier and the condition flags to determine whether the instruction must be executed:

```
// ConditionPassed()
// =============
boolean ConditionPassed()
return ConditionHolds(AArch32.CurrentCond());
```

```
// ConditionHolds()
// ================
// Return TRUE iff COND currently holds

boolean ConditionHolds(bits(4) cond)
// Evaluate base condition.
  case cond<3:1> of
  when '000' result = (PSTATE.Z == '1'); // EQ or NE
  when '001' result = (PSTATE.C == '1'); // CS or CC
  when '010' result = (PSTATE.N == '1'); // MI or PL
  when '011' result = (PSTATE.V == '1'); // VS or VC
  when '100' result = (PSTATE.C == '1' && PSTATE.Z == '0'); // HI or LS
  when '101' result = (PSTATE.N == PSTATE.V); // GE or LT
when '110' result = (PSTATE.N == PSTATE.V && PSTATE.Z == '0');  // GT or LE
when '111' result = TRUE;                                       // AL

// Condition flag values in the set '111x' indicate always true
// Otherwise, invert condition if necessary.
if cond<0> == '1' && cond != '1111' then
  result = !result;

return result;

Undefined Instruction exception on page G1-3875 describes the handling of conditional instructions that are UNDEFINED or UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see Limitations of the instruction pseudocode on page J9-5760.
F2.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details see Constant shifts.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F2.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

<shift> is an optional shift to be applied to <Rm>. It can be any one of:

- (omitted) No shift.
- LSL #<n> Logical shift left <n> bits. 1 <= <n> <= 31.
- LSR #<n> Logical shift right <n> bits. 1 <= <n> <= 32.
- ASR #<n> Arithmetic shift right <n> bits. 1 <= <n> <= 32.
- ROR #<n> Rotate right <n> bits. 1 <= <n> <= 31.
- RRX Rotate right one bit, with extend. Bit[0] is written to shifter_carry_out, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

--- Note ---

Assemblers can permit the use of some or all of ASR #0, LSL #0, LSR #0, and ROR #0 to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of #0 in the immediate forms of ASR, LSL, LSR, and ROR instructions to specify that no shift is to be performed, that is, that a MOV (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the MOV (register) syntax when the instruction specifies no shift.

--- Encoding ---

The assembler encodes <shift> into two type bits and five immediate bits, as follows:

- (omitted) type = 0b00, immediate = 0.
- LSL #<n> type = 0b00, immediate = <n>.
- LSR #<n> type = 0b01.  
  If <n> < 32, immediate = <n>.  
  If <n> == 32, immediate = 0.
- ASR #<n> type = 0b10.  
  If <n> < 32, immediate = <n>.  
  If <n> == 32, immediate = 0.
- ROR #<n> type = 0b11, immediate = <n>.
- RRX type = 0b11, immediate = 0.
F2.4.2 Register controlled shifts

These are only available in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

**ASR**  Arithmetic shift right, encoded as type = 0b10.
**LSL**  Logical shift left, encoded as type = 0b00.
**LSR**  Logical shift right, encoded as type = 0b01.
**ROR**  Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

F2.4.3 Pseudocode description of instruction-specified shifts and rotates

```plaintext
enum SRTyp {SRTyp_LSL, SRTyp_LSR, SRTyp_ASR, SRTyp_ROR, SRTyp_RRX};

// DecodeImmShift()
// ================
(SRTyp, integer) DecodeImmShift(bits(2) type, bits(5) imm5)

  case type of
    when '00' shift_t = SRTyp_LSL; shift_n = UInt(imm5);
    when '01' shift_t = SRTyp_LSR; shift_n = if imm5 == '00000' then 32 else UInt(imm5);
    when '10' shift_t = SRTyp_ASR; shift_n = if imm5 == '00000' then 32 else UInt(imm5);
    when '11' if imm5 == '00000' then
        shift_t = SRTyp_RRX; shift_n = 1;
      else
        shift_t = SRTyp_ROR; shift_n = UInt(imm5);
  return (shift_t, shift_n);

// DecodeRegShift()
// ================
SRTyp DecodeRegShift(bits(2) type)

  case type of
    when '00' shift_t = SRTyp_LSL;
    when '01' shift_t = SRTyp_LSR;
    when '10' shift_t = SRTyp_ASR;
    when '11' shift_t = SRTyp_ROR;
  return shift_t;

// Shift()
// =======
bits(N) Shift(bits(N) value, SRTyp type, integer amount, bit carry_in)
  (result, -) = Shift_C(value, type, amount, carry_in);
  return result;

// Shift_C()
// ========
(bits(N), bit) Shift_C(bits(N) value, SRTyp type, integer amount, bit carry_in)
  assert !(type == SRTyp_RRX && amount != 1);
  if amount == 0 then
    (result, carry_out) = (value, carry_in);
  else
    case type of
      when SRTyp_LSL
        (result, carry_out) = LSL_C(value, amount);
```
when SRTypen_LSR
  (result, carry_out) = LSR_C(value, amount);
when SRTypen_ASR
  (result, carry_out) = ASR_C(value, amount);
when SRTypen_ROR
  (result, carry_out) = ROR_C(value, amount);
when SRTypen_RRX
  (result, carry_out) = RRX_C(value, carry_in);

return (result, carry_out);
F2.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing
The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>] \]

Pre-indexed addressing
The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

\[ [<Rn>, <offset>]! \]

Post-indexed addressing
The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register.

The assembly language syntax for this mode is:

\[ [<Rn>], <offset> \]

In each case, \(<Rn>\) is the base register. \(<offset>\) can be:

- An immediate constant, such as \(<\text{imm}8>\) or \(<\text{imm}12>\).
- An index register, \(<Rm>\).
- A shifted index register, such as \(<Rm>\, \text{LSL} \#<\text{shift}>\).

For information about unaligned access, endianness, and exclusive access, see:

- Alignment support on page E2-2435.
- Endian support on page E2-2437.
- Synchronization and semaphores on page E2-2466.
F2.6 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a `<registers>` field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit `register_list` field. This section gives more information about these and other possible register list encodings.

In a `register_list` field, each bit corresponds to a single register, and if the `<registers>` field of the assembler instruction includes Rt then `register_list<t>` is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.
  - The exceptions to this rule are:
    - The T1 encoding of `POP` uses an 8-bit register list, and an additional bit, `P`, that corresponds to the PC. This means it can access any of R0-R7 and the PC.
    - The T1 encoding of `PUSH` uses an 8-bit register list, and an additional bit, `M`, that corresponds to the LR. This means it can access any of R0-R7 and the LR.
- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, `M`, corresponding to the LR, and `P`, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.
- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, `M`, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.
- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.
  - The exception to this rule is:
    - The system instructions `LDM` (exception return) and `LDM` (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.
- The T3 and A2 encodings of `POP`, and the T3 and A2 encodings of `PUSH`, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the `Rt` field.

--- Note ---

`POP` is a load operation, and `PUSH` is a store operation.

--- Note ---

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, `registers`, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

--- Note ---

Some floating-point and Advanced SIMD instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a `<list>` field that specifies the registers to be operated on, and the description of the instruction in *Alphabetical list of T32 and A32 base instruction set instructions on page F7-2634* defines the use and encoding of this field.
F2.7 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- Pseudocode description of conditional execution on page F2-2518.
- Pseudocode description of instruction-specified shifts and rotates on page F2-2521.

The following subsection gives additional pseudocode support functions for some of the instructions described in Alphabetical list of T32 and A32 base instruction set instructions on page F7-2634. See also Pseudocode support for the Banked register transfer instructions on page F7-3269.

F2.7.1 Pseudocode description of coprocessor operations

The Coproc_CheckInstr() pseudocode function determines whether a coprocessor instruction is accepted for execution, see Pseudocode description of checking accesses to the conceptual coprocessors CP14 and CP15 on page G1-3912.

TheCoproc.DoneLoading() pseudocode function determines, for an LDC instruction, whether enough words have been loaded:

boolean Coproc.DoneLoading(integer cp_num, bits(32) instr);

The Coproc.DoneStoring() function determines for an STC instruction whether enough words have been stored:

boolean Coproc.DoneStoring(integer cp_num, bits(32) instr);

The Coproc.GetOneWord() function obtains the word for an MRC instruction from the coprocessor:

bits(32) Coproc.GetOneWord(integer cp_num, bits(32) instr);

The Coproc.GetTwoWords() function obtains the two words for an MRRC instruction from the coprocessor:

(bits(32), bits(32)) Coproc.GetTwoWords(integer cp_num, bits(32) instr);

Note The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The Coproc.GetWordToStore() function obtains the next word to store for an STC instruction from the coprocessor:

bits(32) Coproc.GetWordToStore(integer cp_num, bits(32) instr);

The Coproc.InternalOperation() procedure instructs a coprocessor to perform the internal operation requested by a CDP instruction:

Coproc.InternalOperation(integer cp_num, bits(32) instr);

The Coproc.SendLoadedWord() procedure sends a loaded word for an LDC instruction to the coprocessor:

Coproc.SendLoadedWord(bits(32) word, integer cp_num, bits(32) instr);

The Coproc.SendOneWord() procedure sends the word for an MCR instruction to the coprocessor:

Coproc.SendOneWord(bits(32) word, integer cp_num, bits(32) instr);

The Coproc.SendTwoWords() procedure sends the two words for an MCRR instruction to the coprocessor:

Coproc.SendTwoWords(bits(32) word2, bits(32) word1, integer cp_num, bits(32) instr);

Note The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.
The CP14DebugInstrDecode() pseudocode function decodes an accepted access to a CP14 debug register:

```java
boolean CP14InstrDecode(bits(32) instr);
```

The CP14JazelleInstrDecode() pseudocode function decodes an accepted access to a CP14 Jazelle register:

```java
boolean CP14JazelleInstrDecode(bits(32) instr);
```

The CP14TraceInstrDecode() pseudocode function decodes an accepted access to a CP14 Trace register:

```java
boolean CP14TraceInstrDecode(bits(32) instr);
```

The CP15InstrDecode() pseudocode function decodes an accepted access to a CP15 register:

```java
boolean CP15InstrDecode(bits(32) instr);
```

### F2.7.2 Pseudocode details of system calls

The CallSupervisor() pseudocode function generates a Supervisor Call exception. Valid execution of the SVC instruction calls this function.

```java
// AArch32.CallSupervisor()
// ========================
// Calls the Supervisor
AArch32.CallSupervisor(bits(16) immediate)
    if AArch32.CurrentCond() != '1110' then
        immediate = bits(16) UNKNOWN;
    if AArch32.GeneralExceptionsToAArch64() then
        AArch64.CallSupervisor(immediate);
    else
        AArch32.TakeSVCException(immediate);
```

The CallHypervisor() pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.

```java
// AArch32.CallHypervisor()
// ========================
// Performs a HVC call
AArch32.CallHypervisor(bits(16) immediate)
    assert HaveEL(EL2);
    if !ELUsingAArch32(EL2) then
        AArch64.CallHypervisor(immediate);
    else
        AArch32.TakeHVCEXception(immediate);
```
Chapter F3
T32 Base Instruction Set Encoding

This chapter introduces the T32 instruction set and describes how it uses the ARM programmers’ model. It contains the following sections:

• T32 instruction set encoding on page F3-2528.
• 16-bit T32 instruction encoding on page F3-2531.
• 32-bit T32 instruction encoding on page F3-2538.

Note
In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
F3.1 T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- 0b11101.
- 0b11110.
- 0b11111.

Otherwise, the halfword is a 16-bit instruction.

For details of the encoding of 16-bit T32 instructions see 16-bit T32 instruction encoding on page F3-2531.

For details of the encoding of 32-bit T32 instructions see 32-bit T32 instruction encoding on page F3-2538.

F3.1.1 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.
  ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:
    - CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
    - Fully predictable.
  For more information see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
  The AArch32 parts of this manual might sometimes describe as UNPREDICTABLE behavior that ARMv8-A makes CONSTRAINED UNPREDICTABLE.
- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- A bit marked (0) in the encoding diagram of an instruction is not 0, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 0.
- A bit marked (1) in the encoding diagram of an instruction is not 1, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 1.
- It is declared as UNPREDICTABLE in an instruction description or in this chapter.

Unless otherwise specified, T32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

Note
Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The system instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see Undefined Instruction exception on page G1-3875.

For more information about the behavior of T32 instructions in earlier versions of the architecture see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.
F3.1.2 Use of the PC, and use of \( 0b1111 \) as a register specifier

The use of \( 0b1111 \) as a register specifier is not normally permitted in T32 instructions. When a value of \( 0b1111 \) is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This means branch tables can be placed in memory immediately after the instruction.

--- Note ---

ARM deprecates use of the PC as the base register in the STC instruction.

---

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be \( 0b1111 \) for the same purpose.

- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as \( 0b1111 \). The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.

- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - Implicitly, for example, branch instructions.
  - Explicitly by a register specifier of \( 0b1111 \), for example 16-bit MOV (register) instructions.
  - Explicitly by using a register mask, for example LDM instructions.

The address to branch to can be:

- A loaded value, for example, RFE.
- A register value, for example, BX.
- The result of a calculation, for example, TBB or TBH.

The method of choosing the instruction set used after the branch can be:

- Similar to the LDR case, for example, LDM or BX.
- A fixed instruction set other than the one currently being used, for example, the immediate form of BLX.
- Unchanged, for example, branch instructions or 16-bit MOV (register) instructions.
- Set from the SPSR.T bit, for RFE and SUBS PC, LR, #imm8.

- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is \( 0b1111 \), the instruction is a memory hint instead of a load operation.

- If the destination register specifier of an MRC instruction is \( 0b1111 \), bits[31:28] of the value transferred from the coprocessor are written to the N, Z, C, and V condition flags in the APSR, and bits[27:0] are discarded.
F3.1.3 Use of the SP, and use of 0b1101 as a register specifier

In T32 instructions, ARM recommends that the use of 0b1101 as a register specifier specifies the SP.

--- Note ---

- The recommendation that register specifier 0b1101 is used only to specify the SP applies to both the T32 and the A32 instruction sets.

- Despite this recommendation, in ARMv8, most T32 uses of R13 as a general-purpose register behave predictably. This differs from ARMv7, where many uses of R13 are UNPREDICTABLE. For more information, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.
F3.2 16-bit T32 instruction encoding

The encoding of a 16-bit T32 instruction is:

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction or instruction class</th>
</tr>
</thead>
<tbody>
<tr>
<td>00xxxx</td>
<td><em>Shift (immediate), add, subtract, move, and compare</em> on page F3-2532</td>
</tr>
<tr>
<td>010000</td>
<td><em>Data-processing</em> on page F3-2533</td>
</tr>
<tr>
<td>010001</td>
<td><em>Special data instructions and branch and exchange</em> on page F3-2534</td>
</tr>
<tr>
<td>01001x</td>
<td>Load from Literal Pool, see <em>LDR (literal)</em> on page F7-2788</td>
</tr>
<tr>
<td>0101xx</td>
<td><em>Load/store single data item</em> on page F3-2535</td>
</tr>
<tr>
<td>011xxx</td>
<td></td>
</tr>
<tr>
<td>100xxx</td>
<td></td>
</tr>
<tr>
<td>10100x</td>
<td>Generate PC-relative address, see <em>ADR</em> on page F7-2662</td>

</tr>
<tr>
<td>1101xx</td>
<td><em>Conditional branch, and Supervisor Call</em> on page F3-2537</td>
</tr>
<tr>
<td>11100x</td>
<td>Unconditional Branch, see <em>B</em> on page F7-2681</td>
</tr>
</tbody>
</table>

Table F3-1 shows the allocation of 16-bit instruction encodings.
F3.2.1 Shift (immediate), add, subtract, move, and compare

The encoding of 16-bit T32 shift (immediate), add, subtract, move, and compare instructions is:

Table F3-2 shows the allocation of encodings in this space.

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>00xxx</td>
<td>Move&lt;sup&gt;a&lt;/sup&gt;</td>
<td>MOV, MOVS (register) on page F7-2876&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>010xx</td>
<td></td>
<td></td>
</tr>
<tr>
<td>01100</td>
<td>Add register</td>
<td>ADD, ADDS (register) on page F7-2647</td>
</tr>
<tr>
<td>01101</td>
<td>Subtract register</td>
<td>SUB, SUBS (register) on page F7-3156</td>
</tr>
<tr>
<td>01110</td>
<td>Add 3-bit immediate</td>
<td>ADD, ADDS (immediate) on page F7-2643</td>
</tr>
<tr>
<td>01111</td>
<td>Subtract 3-bit immediate</td>
<td>SUB, SUBS (immediate) on page F7-3152</td>
</tr>
<tr>
<td>100xx</td>
<td>Move</td>
<td>MOV, MOVS (immediate) on page F7-2873</td>
</tr>
<tr>
<td>101xx</td>
<td>Compare</td>
<td>CMP (immediate) on page F7-2714</td>
</tr>
<tr>
<td>110xx</td>
<td>Add 8-bit immediate</td>
<td>ADD, ADDS (immediate) on page F7-2643</td>
</tr>
<tr>
<td>111xx</td>
<td>Subtract 8-bit immediate</td>
<td>SUB, SUBS (immediate) on page F7-3152</td>
</tr>
</tbody>
</table>

<sup>a</sup> Previous descriptions of the 16-bit T32 encodings have included the immediate forms of ASR<S>), LSL<S>, and LSR<S>. These are aliases of MOV<S> (register) and their encoding is now described in MOV, MOVS (register) on page F7-2876.
Data-processing

The encoding of 16-bit T32 data-processing instructions is:

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Bitwise AND</td>
<td>AND, ANDS (register) on page F7-2667</td>

<td>ORR, ORRS (register) on page F7-2920</td>
</tr>
<tr>
<td>1101</td>
<td>Multiply</td>
<td>MUL, MULS on page F7-2904</td>
</tr>
<tr>
<td>1110</td>
<td>Bitwise Bit Clear</td>
<td>BIC, BICS (register) on page F7-2690</td>
</tr>
<tr>
<td>1111</td>
<td>Bitwise NOT</td>
<td>MVN, MVNS (register) on page F7-2908</td>
</tr>
</tbody>
</table>

Table F3-3 shows the allocation of encodings in this space.

a. Previous descriptions of the 16-bit T32 encodings have included the register forms of ASR{S}, LSL{S}, LSR{S}, and ROR{S}. These are aliases of MOV{S} (register-shifted register) and their encoding is now described in MOV, MOVS (register-shifted register) on page F7-2881.
### Special data instructions and branch and exchange

The encoding of 16-bit T32 special data instructions and branch and exchange instructions is:

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>00xx</td>
<td>Add registers</td>
<td>Add registers</td>
</tr>
<tr>
<td>01xx</td>
<td>Compare High Registers</td>
<td>CMP (register) on page F7-2716</td>
</tr>
<tr>
<td>1000</td>
<td>Move Low Registers</td>
<td>MOV, MOVS (register) on page F7-2876</td>
</tr>
<tr>
<td>1001</td>
<td>Move High Registers</td>
<td>MOV, MOVS (register) on page F7-2876</td>

<td>ADD, ADDS (register) on page F7-2647</td>
</tr>
</tbody>
</table>
F3.2.4 Load/store single data item

The encoding of 16-bit T32 instructions that load or store a single data item is:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>opA</th>
<th>opB</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
</tr>
<tr>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

These instructions have one of the following values of \( opA \):

- \( 0b0101 \)
- \( 0b011x \)
- \( 0b100x \)

Table F3-6 shows the allocation of encodings in this space.

<table>
<thead>
<tr>
<th>Table F3-6 16-bit T32 Load/store single data item instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>opA</strong></td>
</tr>
<tr>

F3.3.1 Data-processing (modified immediate)

The encoding of the 32-bit T32 data-processing (modified immediate) instructions is:

```
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 1 1 1 1 0 | op | S | Rn | 0 | Rd |
```

Table F3-11 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

**Table F3-11 32-bit modified immediate data-processing instructions**

</tr>
</tbody>
</table>

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see Modified immediate constants in T32 instructions on page F3-2540.
F3.3.2 Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>i:imm3:a</th>
<th>&lt;const&gt; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000x</td>
<td>00000000 00000000 00000000 abcdefgh</td>
<td></td>
</tr>
<tr>
<td>0001x</td>
<td>00000000 abcdefgh 00000000 abcdefgh b</td>
<td></td>
</tr>
<tr>
<td>0010x</td>
<td>abcdefgh 00000000 abcdefgh 00000000 b</td>
<td></td>
</tr>
<tr>
<td>0011x</td>
<td>abcdefgh abcdefgh abcdefgh abcdefgh b</td>
<td></td>
</tr>
<tr>
<td>01000</td>
<td>1bcdefgh 00000000 00000000 00000000</td>
<td></td>
</tr>
<tr>
<td>01001</td>
<td>01bcdefgh 00000000 00000000 00000000 c</td>
<td></td>
</tr>
<tr>
<td>01010</td>
<td>001bcdefgh 00000000 00000000 00000000</td>
<td></td>
</tr>
<tr>
<td>01011</td>
<td>0001bcdefgh 00000000 00000000 00000000 c</td>
<td></td>
</tr>
</tbody>
</table>

a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

Table F3-12 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>i:imm3:a</th>
<th>&lt;const&gt; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>01011</td>
<td>0001bcdefgh 00000000 00000000 00000000 c</td>
<td></td>
</tr>
</tbody>
</table>

b. ARM deprecates using a modified immediate with abcdefgh == 00000000.

c. Not available in A32 instructions if h == 1.

--- Note ---

As the footnotes to Table F3-12 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See Modified immediate constants in A32 instructions on page F4-2569 for the A32 values.

--- Carry out ---

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.
Operation of modified immediate constants, T32 instructions

// T32ExpandImm()
// ===============

bits(32) T32ExpandImm(bits(12) imm12)

  // PSTATE.C argument to following function call does not affect the imm32 result.
  (imm32, -) = T32ExpandImm_C(imm12, PSTATE.C);

  return imm32;

// T32ExpandImm_C()
// ==============

(bits(32), bit) T32ExpandImm_C(bits(12) imm12, bit carry_in)

  if imm12<11:10> == '00' then
    case imm12<9:8> of
      when '00'
        imm32 = ZeroExtend(imm12<7:0>, 32);
      when '01'
        imm32 = '00000000' : imm12<7:0> : '00000000' : imm12<7:0>;
      when '10'
        imm32 = imm12<7:0> : '00000000' : imm12<7:0> : '00000000';
      when '11'
        imm32 = imm12<7:0> : imm12<7:0> : imm12<7:0> : imm12<7:0>;
      else
        unrotated_value = ZeroExtend('1':imm12<6:0>, 32);
        (imm32, carry_out) = ROR_C(unrotated_value, UInt(imm12<11:7>));
    end case;
  else
  end if;

  return (imm32, carry_out);
F3.3.3 Data-processing (plain binary immediate)

The encoding of the 32-bit T32 data-processing (plain binary immediate) instructions is:

```
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 1 1 1 1 1 0 | 1 | op | Rn | 0 |
```

Table F3-13 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

Change PE State, and hints

The encoding of 32-bit T32 Change PE State and hint instructions is:

Table F3-15 shows the allocation of encodings in this space. Encodings with op1 set to 0b000 and a value of op2 that is not shown in the table are unallocated hints, and behave as if op2 is set to 0b00000000. These unallocated hint encodings are reserved and software must not use them.

</tbody>
</table>

### Table F3-23 Data-processing (shifted register)

- Previous descriptions of the 32-bit T32 encodings have included RRX{S} and the immediate forms of ASR{S}, LSL{S}, LSR{S}, and ROR{S}. These are aliases of MOV{S} (register) and their encoding is now described in MOV, MOVS (register) on page F7-2876.
F3.3.12 Data-processing (register)

The encoding of 32-bit T32 data-processing (register) instructions is:

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 1 1 1 1 1 0 1 0 | op1 | 1 1 1 1 | Rn | 0 1 1 0 | op2 |

If, in the second halfword of the instruction, bits [15:12] != 0b1111, the instruction is UNDEFINED.

Table F3-24 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

Miscellaneous operations

The encoding of some 32-bit T32 miscellaneous instructions is:

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 1 1 1 1 1 0 1 0 1 | op1 | 1 1 1 1 | op2 | 1 0 |

If, in the second halfword of the instruction, bits[15:12] ≠ 0b1111, the instruction is UNDEFINED.

Table F3-27 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

Chapter F4
A32 Base Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- A32 instruction set encoding on page F4-2562.
- Data-processing and miscellaneous instructions on page F4-2565.
- Load/store word and unsigned byte on page F4-2577.
- Media instructions on page F4-2578.
- Branch, branch with link, and block data transfer on page F4-2583.
- Coprocessor instructions, and Supervisor Call on page F4-2584.
- Unconditional instructions on page F4-2585.

______ Note ________
In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

_________
F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is a single 32-bit word in that stream. The encoding of an A32 instruction is:

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
</tr>
<tr>
<td>28</td>
<td>27</td>
<td>26</td>
</tr>
<tr>
<td>25</td>
<td>24</td>
<td>23</td>
</tr>
<tr>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>19</td>
<td>18</td>
<td>17</td>
</tr>
<tr>
<td>16</td>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>13</td>
<td>12</td>
<td>11</td>
</tr>
<tr>
<td>10</td>
<td>9</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Table F4-1 shows the major subdivisions of the A32 instruction set, determined by bits [31:25, 4].

Most A32 instructions can be conditional, with a condition determined by bits [31:28] of the instruction, the cond field. For more information see The condition code field. This applies to all instructions except those with the cond field equal to 0b1111.

Table F4-1 A32 instruction encoding

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op</th>
<th>Instruction classes</th>
</tr>
</thead>
<tbody>
<tr>
<td>not 1111</td>
<td>00x</td>

</tr>
<tr>
<td>011 0</td>
<td>Load/store word and unsigned byte on page F4-2577.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>Media instructions on page F4-2578.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>10x</td>
<td>-</td>
<td>Branch, branch with link, and block data transfer on page F4-2583.</td>
<td></td>
</tr>
<tr>
<td>11x</td>
<td>-</td>
<td>Coprocessor instructions, and Supervisor Call on page F4-2584. Includes floating-point instructions and Advanced SIMD data transfers, see Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings.</td>
<td></td>
</tr>
<tr>
<td>1111</td>
<td>-</td>
<td>If the cond field is 0b1111, the instruction can only be executed unconditionally, see Unconditional instructions on page F4-2585. Includes Advanced SIMD instructions, see Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings.</td>
<td></td>
</tr>
</tbody>
</table>

F4.1.1 The condition code field

Every conditional instruction contains a 4-bit condition code field, the cond field, in bits 31 to 28:

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
</tr>
<tr>
<td>28</td>
<td>27</td>
<td>26</td>
</tr>
<tr>
<td>25</td>
<td>24</td>
<td>23</td>
</tr>
<tr>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>19</td>
<td>18</td>
<td>17</td>
</tr>
<tr>
<td>16</td>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>13</td>
<td>12</td>
<td>11</td>
</tr>
<tr>
<td>10</td>
<td>9</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

This field contains one of the values 0b0000-0b1111, as shown in Table F2-1 on page F2-2517. Most instruction mnemonics can be extended with the letters defined in the mnemonic extension column of this table.

If the always (AL) condition is specified, the instruction is executed irrespective of the value of the condition flags. The absence of a condition code on an instruction mnemonic implies the AL condition code.
F4.1.2 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.
  ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:
  - CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
  - Fully predictable.
  For more information see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- It is declared as UNPREDICTABLE in an instruction description or in this chapter.
- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively.

Unless otherwise specified, A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

Note
Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The system instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see Undefined Instruction exception on page G1-3875.

For more information about the behavior of A32 instructions in earlier versions of the architecture see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

F4.1.3 The PC and the use of 0b1111 as a register specifier

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are UNPREDICTABLE if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. ARMv8-A constrains the resulting UNPREDICTABLE behavior, see Using R15 on page J1-5363.

Note
ARM deprecates use of the PC as the base register in any store instruction.
F4.1.4 The SP and the use of 0b1101 as a register specifier

In A32 instructions, the use of 0b1101 as a register specifier specifies the SP.

This applies to both A32 and T32 in AArch32 state. ARM deprecates using SP for any purpose other than as a stack pointer.
F4.2 Data-processing and miscellaneous instructions

The encoding of A32 data-processing instructions, and some miscellaneous, instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>0</th>
<th>op</th>
<th>op1</th>
<th>op2</th>
</tr>
</thead>
</table>
|0xx0| 0xx0| Data-processing (register) on page F4-2566
|0xx1| 0xx1| Data-processing (register-shifted register) on page F4-2567
|1xx0| 0xx0| Miscellaneous instructions on page F4-2576
|0xxxx| 1001| Halfword multiply and multiply accumulate on page F4-2572
|1xxxx| 1001| Multiply and multiply accumulate on page F4-2571
|not 0xx1x| 1011| Extra load/store instructions on page F4-2572
|11x1| 11x1| Extra load/store instructions on page F4-2572
|0xx10| 11x1| Extra load/store instructions on page F4-2572
|0xx1x| 1011| Extra load/store instructions, unprivileged on page F4-2573
|0xx11| 11x1| Extra load/store instructions, unprivileged on page F4-2573

For encodings where cond == 1111, see Unconditional instructions on page F4-2585. Table F4-2 shows the allocation of encodings in this space.

</tbody>
</table>

For encodings where cond == 1111, see *Unconditional instructions* on page F4-2585.

Table F4-3 shows the allocation of encodings in this space. These encodings are in all architecture variants.

#### Table F4-3 Data-processing (register) instructions

- Previous descriptions of the A32 encodings have included \( \text{RRX}\{S\} \) and the immediate forms of \( \text{ASR}\{S\}, \text{LSL}\{S\}, \text{LSR}\{S\}, \text{and} \ \text{ROR}\{S\}. \) These are aliases of \( \text{MOV}\{S\} \) (register) and their encoding is now described in *MOV, MOVs (register)* on page F7-2876.
F4.2 Data-processing and miscellaneous instructions

The encoding of A32 data-processing (register-shifted register) instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>0</th>
<th>1</th>
</tr>
</thead>
</table>

For encodings where $\text{cond} == 1111$, see Unconditional instructions on page F4-2585.

Table F4-4 shows the allocation of encodings in this space.

<table>
<thead>
<tr>

</table>

* Previous descriptions of the A32 encodings have included the register forms of ASR(S), LSL(S), LSR(S), and ROR(S). These are aliases of MOV(S) (register-shifted register) and their encoding is now described in MOV, MOVS (register-shifted register) on page F7-2881.*
F4.2.3 Data-processing (immediate)

The encoding of A32 data-processing (immediate) instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>op</th>
<th>Rn</th>
</tr>
</thead>
</table>

For encodings where $\text{cond} == 1111$, see Unconditional instructions on page F4-2585.

Table F4-5 shows the allocation of encodings in this space.

<table>
<thead>
<tr>

<tr>
<td>1111x</td>
<td>-</td>
<td>Bitwise NOT</td>
<td>MVN, MVNS (immediate) on page F7-2906</td>
</tr>
</tbody>
</table>

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see Modified immediate constants in A32 instructions on page F4-2569.
F4.2.4 Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

```
 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

Table F4-6 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

Table F4-6 Encoding of modified immediates in A32 processing instructions

<td>00000000 00000000 00000000 00000000</td>
</tr>
</tbody>
</table>

a. This table shows the immediate constant value in binary form, to relate abedefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

--- Note ---

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See Modified immediate constants in T32 instructions on page F3-2540.

--- Carry out ---

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

--- Constants with multiple encodings ---

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F4-6. For example, the constant #3 must be encoded with (rotation, abedefgh) == (0b0000, 0b00000011), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).
In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte> Is the numeric value of abcd, in the range 0-255.
<rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and ARM deprecates their use.

Operation of modified immediate constants, A32 instructions

// A32ExpandImm()
// ===============
bits(32) A32ExpandImm(bits(12) imm12)

  // PSTATE.C argument to following function call does not affect the imm32 result.
  (imm32, -) = A32ExpandImm_C(imm12, PSTATE.C);

  return imm32;

// A32ExpandImm_C()
// ================
(bits(32), bit) A32ExpandImm_C(bits(12) imm12, bit carry_in)

  unrotated_value = ZeroExtend(imm12<7:0>, 32);
  (imm32, carry_out) = Shift_C(unrotated_value, SRTYPE_ROR, 2*UInt(imm12<11:8>), carry_in);

  return (imm32, carry_out);
F4.2.5  Multiply and multiply accumulate

The encoding of A32 multiply and multiply accumulate instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>op</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>000x</td>
<td></td>
<td>Multiply</td>
<td>MUL, MULS on page F7-2904</td>

</tr>
<tr>
<td>111x</td>
<td></td>
<td>Signed Multiply Accumulate Long</td>
<td>SMLAL, SMLALS on page F7-3046</td>
</tr>
</tbody>
</table>

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

Table F4-7 shows the allocation of encodings in this space.

F4.2.6  Saturating addition and subtraction

The encoding of A32 saturating addition and subtraction instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>op</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>000x</td>
<td>0</td>
<td>Saturating Add</td>
<td>QADD on page F7-2949</td>
</tr>
<tr>
<td>01</td>

<td>QSUB on page F7-2962</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>Saturating Double and Add</td>
<td>QDADD on page F7-2956</td>
</tr>
<tr>
<td>11</td>
<td></td>
<td>Saturating Double and Subtract</td>
<td>QDSUB on page F7-2958</td>
</tr>
</tbody>
</table>

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

Table F4-8 shows the allocation of encodings in this space.
F4.2.7  Halfword multiply and multiply accumulate

The encoding of A32 halfword multiply and multiply accumulate instructions is:

```
cond  0  0  0  1  0  op1  0  op  0
```

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

Table F4-9 shows the allocation of encodings in this space.

These encodings are signed multiply (SMUL) and signed multiply accumulate (SMLA) instructions, operating on 16-bit values, or mixed 16-bit and 32-bit values. The results and accumulators are 32-bit or 64-bit.

<table>
<thead>
<tr>

</tbody>
</table>

F4.2.8  Extra load/store instructions

The encoding of extra A32 load/store instructions is:

```
cond  0  0  0  1  Rn  1  op2  1
```

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

If (op2 == 0b00) then see Data-processing and miscellaneous instructions on page F4-2565.

If ((op1 == 0b00xx10) & (op2 == 0b01)) or ((op1 == 0b0xx11) & (op2 != 0b00)) then see Extra load/store instructions, unprivileged on page F4-2573.

Otherwise, Table F4-10 shows the allocation of encodings in this space.

<table>
<thead>

</tr>
</tbody>
</table>

For encodings where cond = 1111, see Unconditional instructions on page F4-2585.

Table F4-12 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED.
F4.2.11 MSR (immediate), and hints

The encoding of A32 MSR (immediate) and hint instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>op</th>
<th>1</th>
<th>0</th>
<th>op1</th>
<th>op2</th>
</tr>
</thead>
</table>

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

Table F4-13 shows the allocation of encodings in this space. Encodings with op set to 0, op1 set to 0b0000, and a value of op2 that is not shown in the table, are unallocated hints and behave as if op2 is set to 0b00000000. These unallocated hint encodings are reserved and software must not use them.

<table>
<thead>
<tr>
<th>op</th>
<th>op1</th>
<th>op2</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0000</td>
<td>0000000</td>
<td>No Operation hint</td>
<td>NOP on page F7-2913</td>
</tr>
<tr>

F4.3 Load/store word and unsigned byte

The encoding of A32 load/store word and unsigned byte instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>1</th>
<th>A</th>
<th>op1</th>
<th>Rn</th>
<th>B</th>
</tr>
</thead>
</table>

For encodings where `cond == 1111`, see *Unconditional instructions* on page F4-2585.

These instructions have either `A == 0` or `B == 0`. For instructions with `A == 1` and `B == 1`, see *Media instructions* on page F4-2578.

Otherwise, Table F4-15 shows the allocation of encodings in this space.

</table>

^ The mnemonic applies only to the unconditional encoding, with cond set to 0b1110.

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

Table F4-16 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED.
F4.4.1 Parallel addition and subtraction, signed

The encoding of A32 signed parallel addition and subtraction instructions is:

|cond| 0| 1| 1| 0| 0| op1| | op2| 1|
|-----|-----|-----|-----|-----|-----|-----|-----|-----|

For encodings where cond == 1111, see Unconditional instructions on page F4-2585.

Table F4-17 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED.

b. See Table F4-16 on page F4-2578 for the full range of encodings in this permanently UNDEFINED group.
F4 A32 Base Instruction Set Encoding
F4.7 Unconditional instructions
Chapter F5
T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings

This chapter gives an overview of the Advanced SIMD and floating-point instruction sets. It contains the following sections:

• Overview on page F5-2590.
• Advanced SIMD and floating-point instruction syntax on page F5-2591.
• Register encoding on page F5-2595.
• Advanced SIMD data-processing instructions on page F5-2597.
• Floating-point data-processing instructions on page F5-2609.
• Advanced SIMD and floating-point register load/store instructions on page F5-2612.
• Advanced SIMD element or structure load/store instructions on page F5-2613.
• 8, 16, and 32-bit transfers accessing the SIMD and floating-point register file on page F5-2616.
• 64-bit transfers accessing the SIMD and floating-point register file on page F5-2617.

Note

• The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.
• In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
F5.1 Overview

All Advanced SIMD and floating-point instructions are available in both A32 and T32 instruction sets.

F5.1.1 Advanced SIMD

The following sections describe the classes of Advanced SIMD instructions:
- Advanced SIMD data-processing instructions on page F5-2597.
- Advanced SIMD element or structure load/store instructions on page F5-2613.
- Advanced SIMD and floating-point register load/store instructions on page F5-2612.
- 8, 16, and 32-bit transfers accessing the SIMD and floating-point register file on page F5-2616.
- 64-bit transfers accessing the SIMD and floating-point register file on page F5-2617.

F5.1.2 Floating-point

The following sections describe the classes of floating-point instructions:
- Advanced SIMD and floating-point register load/store instructions on page F5-2612.
- 8, 16, and 32-bit transfers accessing the SIMD and floating-point register file on page F5-2616.
- 64-bit transfers accessing the SIMD and floating-point register file on page F5-2617.
- Floating-point data-processing instructions on page F5-2609.
F5.2 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets. Advanced SIMD and floating-point data-processing instructions use the following general format:

\[ V\{\text{modifier}\}\{\text{operation}\}\{\text{shape}\}\{\text{<c>}\}\{\text{<q>}\}\{\text{.dt}\}\{\text{dest}\},\text{src1},\text{src2}\} \]

All Advanced SIMD and floating-point instructions begin with a \( V \). This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the \( \text{operation} \) field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The \( \text{<c>} \) and \( \text{<q>} \) fields are standard assembler syntax fields. For details see Standard assembler syntax fields on page F2-2516.

F5.2.1 Advanced SIMD instruction modifiers

The \( \text{<modifier>} \) field provides additional variants of some instructions. Table F5-1 provides definitions of the modifiers. Modifiers are not available for every instruction.

<table>
<thead>
<tr>
<th>( \text{&lt;modifier&gt;} )</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q</td>
<td>The operation uses saturating arithmetic.</td>
</tr>
<tr>
<td>R</td>
<td>The operation performs rounding.</td>
</tr>
<tr>
<td>D</td>
<td>The operation doubles the result (before accumulation, if any).</td>
</tr>
<tr>
<td>H</td>
<td>The operation halves the result.</td>
</tr>
</tbody>
</table>

F5.2.2 Advanced SIMD operand shapes

The \( \text{<shape>} \) field provides additional variants of some instructions. Table F5-2 provides definitions of the shapes. Operand shapes are not available for every instruction.

<table>
<thead>
<tr>
<th>( \text{&lt;shape&gt;} )</th>
<th>Meaning</th>
<th>Typical register shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>(none)</td>
<td>The operands and result are all the same width.</td>
<td>Dd, Dn, Dm</td>
</tr>
<tr>
<td>L</td>
<td>Long operation - result is twice the width of both operands</td>
<td>Qd, Dn, Dm</td>
</tr>
<tr>
<td>N</td>
<td>Narrow operation - result is half the width of both operands</td>
<td>Dd, Qn, Qm</td>
</tr>
<tr>
<td>W</td>
<td>Wide operation - result and first operand are twice the width of the second operand</td>
<td>Qd, Qn, Dm</td>
</tr>
</tbody>
</table>

--- Note ---

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is \( \text{VADDQ.S32 q0, q1, q2} \). This is not standard UAL, and ARM recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in Table F5-2.
F5.2.3 Data type specifiers

The `<dt>` field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the `<dt>` field combined with the instruction shape. For information about data type formats see *Data types supported by the Advanced SIMD implementation* on page E1-2396.

In the instruction syntax descriptions in *Chapter F2 About the T32 and A32 Instruction Descriptions*, the `<dt>` field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, `<type><size>`.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:
  
  ```
  VSUBW.I16.I16.S8 Q3, Q5, D0
  ```
  instead of
  
  ```
  VSUBW.S8 Q3, Q5, D0
  ```

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:
  
  ```
  VSUBW.I16.S8 Q3, Q5, D0
  ```
  instead of
  
  ```
  VSUBW.S8 Q3, Q5, D0
  ```

- Software can specify two data types, specifying the data types of the single operand and the result. For example:
  
  ```
  VMOVN.I16.I32 D0, Q1
  ```
  instead of
  
  ```
  VMOVN.I32 D0, Q1
  ```

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in Table F5-3.

- Where an instruction does not require a data type, software can provide one.

- The F32 data type can be abbreviated to F.

- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

Table F5-3 Data type specification flexibility

<table>
<thead>
<tr>
<th>Specified data type</th>
<th>Permitted more specific data types</th>
</tr>
</thead>

</tr>
<tr>
<td><code>.64</code></td>
<td><code>.I64</code> <code>.S64</code> <code>.U64</code> - <code>.F64</code> or <code>.D</code></td>
</tr>
</tbody>
</table>
F5.2.4 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F5-4 shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

Table F5-4 Advanced SIMD and floating-point register specifier formats

</tr>
<tr>
<td>&lt;Rm&gt;</td>
<td>A general-purpose register, used as a post-indexed address source.</td>
<td>Both</td>
</tr>
</tbody>
</table>

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, <Dn[x]> is used only in VMOV (scalar to general-purpose register), see VMOV (scalar to general-purpose register) on page F8-3550.
F5.2.5 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F5-5 shows some register list formats, with examples of actual register lists corresponding to those formats.

——— Note ————
Register lists must not wrap around the end of the register bank.

Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example \{D0-D3\} instead of \{D0, D1, D2, D3\}.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example \{Q1, Q2\} instead of \{D2-D5\}.
- Where a register list contains only one register, the enclosing braces can be omitted, for example VLD1.8 D0, [R0] instead of VLD1.8 \{D0\}, [R0].

<table>

<td>(D3, D4, D5)</td>
<td>(D3-D5)</td>
</tr>
<tr>
<td>{&lt;Dd[x]&gt;,&lt;Dd+2[x]&gt;}</td>
<td>(D0[3], D2[3])</td>
<td>-</td>
</tr>
<tr>
<td>{&lt;Dd[]&gt;}</td>
<td>(D7[])</td>
<td>D7[]</td>
</tr>
</tbody>
</table>
F5.3 Register encoding

An Advanced SIMD register is either:

- **Quadword**, meaning it is 128 bits wide.
- **Doubleword**, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

- **Double-precision**, meaning it is 64 bits wide.
- **Single-precision**, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

```
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------|--------|--------|--------|--------|
| D | Vn | Vd | sz | N | Q | M | Vm |
```

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------|--------|--------|--------|--------|
| D | Vn | Vd | sz | N | Q | M | Vm |
```

Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F5-6 shows the encodings for the registers.

### Table F5-6 Encoding of register numbers

<td>Vm, M (bits[3:0, 5])</td>
<td>-</td>
<td>Floating-point</td>
</tr>
</tbody>
</table>

\(^{a}\) Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.

\(^{b}\) If this bit is 1, the instruction is UNDEFINED.
F5.3.1 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F5-7 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, $D_m[x]$ in a 32-bit context ($0 \leq m \leq 15$, $0 \leq x \leq 1$) is equivalent to $S[2m+x]$.

</tr>
</tbody>
</table>
F5.4 **Advanced SIMD data-processing instructions**

The T32 encoding of Advanced SIMD data processing instructions is:

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 U 1 1 1 A B C
```

The A32 encoding of Advanced SIMD data processing instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 0 0 1 U A B C
```

Table F5-8 shows the encoding for Advanced SIMD data-processing instructions. Other encodings in this space are UNDEFINED.

In these instructions, the U bit is in a different location in A32 and T32 instructions. This is bit[12] of the first halfword in the T32 encoding, and bit[24] in the A32 encoding. Other variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the IT instruction. For details see IT on page F7-2750.

<sup>a</sup> Previous descriptions of the A32/T32 Advanced SIMD encodings have included VMOV (register, SIMD). This is an alias of an encoding of VORR (register), and its encoding is now described in VORR (register) on page F8-3594.

<sup>b</sup> Vector Compare Less Than or Equal, VCLE, is an alias of VCGE and is described in the same section.

<sup>c</sup> Vector Compare Less Than, VCLT, is an alias of VCGT and is described in the same section.

<sup>d</sup> Vector Absolute Compare Less Than or Equal, VACLE, is an alias of VACGE and is described in the same section.

<sup>e</sup> Vector Absolute Compare Less Than, VACLT, is an alias of VACGT and is described in the same section.
F5.4.2 Three registers of different lengths

The T32 encoding of these instructions is:

```
| 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0 |
| 1 1 1 U 1 1 1 1 | B | A | 0 | 0 |
```

The A32 encoding of these instructions is:

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0 |
| 1 1 1 1 0 0 1 | U 1 | B | A | 0 | 0 |
```

If B == 0b11, see Advanced SIMD data-processing instructions on page F5-2597.

Otherwise, Table F5-10 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

</table>

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.

b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, VMOV.I64 D0, #0x8000000080000000 does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as VMOV.I32 D0, #0x80000000.

c. This constant is available for the VBIC, VMOV, VMVN, and VORR instructions.

d. UNPREDICTABLE if abcdefgh == 00000000.

e. This constant is available for the VMOV and VMVN instructions only.

f. This constant is available for the VMOV instruction only.

g. In this entry, B = NOT(b). The bit pattern represents the floating-point number \((-1)^S \times 2^{\text{exp}} \times \text{mantissa}\), where \(S = \text{UInt}(a)\), \(\text{exp} = \text{UInt}(\text{NOT}(b):c:d) - 3\) and \(\text{mantissa} = (16 + \text{UInt}(e:f:g:h))/16\).
Advanced SIMD expand immediate pseudocode

**F5.5 Floating-point data-processing instructions**

The T32 encoding of floating-point data processing instructions is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 1 0 opc1 opc2 1 0 1 opc3 0 opc4</td>
</tr>
</tbody>
</table>

The A32 encoding of floating-point data processing instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>cond 1 1 1 0 opc1 opc2 1 0 1 opc3 0 opc4</td>
</tr>
</tbody>
</table>

Table F5-16 shows the decode of these instructions. Other encodings in this space are UNDEFINED.

Table F5-16 shows the full decode of encodings for three-register floating-point data-processing instructions. *Other floating-point data processing instructions on page F5-2610* shows the additional decoding of the other floating-point data-processing instructions.

These instructions are CDP instructions for coprocessors 10 and 11.

</tbody>
</table>

a. In this column, B = NOT(b). The bit pattern represents the floating-point number \((-1)^S \times 2^\text{exp} \times \text{mantissa}\), where \(S = \text{UInt}(a)\), \(\text{exp} = \text{UInt}(\text{NOT}(b):c:d)-3\) and mantissa \(= (16+\text{UInt}(e:f:g:h))/16\).

F5.5.2 Operation of modified immediate constants, floating-point

The VFPEXpandImm() pseudocode function describes the operation of an immediate constant in a floating-point instruction.

// VFPEXpandImm()
// ============

bits(N) VFPEXpandImm(bits(8) imm8)
assert N IN {32,64};
constant integer E = (if N == 32 then 8 else 11);
constant integer F = N - E - 1;
sign = imm8<7>;
exp = NOT(imm8<6>);Replicate(imm8<6>,E-3):imm8<5:4>;
frac = imm8<3:0>:Zeros(F-4);
return sign : exp : frac;
F5.6 Advanced SIMD and floating-point register load/store instructions

These are instructions that transfer data to or from the registers in the SIMD and floating-point register file.

The T32 encoding of Advanced SIMD and floating-point register load or store instructions is:

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>0010x</td>
<td>-</td>
<td>64-bit transfers accessing the SIMD and floating-point register file on page F5-2617</td>

</tr>
<tr>
<td>10x11</td>
<td>Vector Load Multiple ( ^b )</td>
<td>VLDM, VLMDB, VLDMIA on page F8-3492 ( ^b )</td>
</tr>
<tr>
<td>1xx01</td>
<td>Vector Load Register</td>
<td>VLDR on page F8-3496</td>
</tr>
</tbody>
</table>

If \( T == 1 \) in the T32 encoding or \( \text{cond} == 0b1111 \) in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-20. Other encodings in this space are UNDEFINED.

These instructions are LDC and STC instructions for coprocessors 10 and 11.

### Table F5-20 Advanced SIMD and floating-point register load/store instructions

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>

<td>Vector Load Register</td>
<td>VLDR on page F8-3496</td>
</tr>
</tbody>
</table>

\( ^a \) Previous descriptions of the T32/A32 Advanced SIMD and floating-point encodings have included \( \text{VPUSH} \). This is an alias of an encoding of \( \text{VSTM} \), and its encoding is now described in \( \text{VSTM}, \text{VSTMDB}, \text{VSTMIA} \) on page F8-3771.

\( ^b \) Previous descriptions of the T32/A32 Advanced SIMD and floating-point encodings have included \( \text{VPOP} \). This is an alias of an encoding of \( \text{VLDM} \), and its encoding is now described in \( \text{VLDM}, \text{VLDMDB}, \text{VLDMIA} \) on page F8-3492.
F5.7 Advanced SIMD element or structure load/store instructions

These are instructions that transfer data to or from Advanced SIMD elements or structures in the SIMD and floating-point register file.

The T32 encoding of Advanced SIMD element load or store instructions is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>A</th>
<th>L</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 1 1 1 0 0 1</td>
<td>A</td>
<td>L</td>
<td>0</td>
</tr>
</tbody>
</table>

The A32 encoding of Advanced SIMD element load or store instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>A</th>
<th>L</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 1 1 0 1 0 0</td>
<td>A</td>
<td>L</td>
<td>0</td>
</tr>
</tbody>
</table>

The allocation of encodings in this space is shown in:

- Table F5-21 if \( L = 0 \). These are the encodings for store instructions.
- Table F5-22 on page F5-2614 if \( L = 1 \). These are the encodings for load instructions.

Other encodings in this space are UNDEFINED.

The variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the IT instruction. For details see IT on page F7-2750.

</tbody>
</table>
F5.7.1 Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

```
[Rn]:<align>
```

The address is contained in general-purpose register Rn. Rn is not updated by this instruction.

- Encoded as Rm = 0b1111.
- If Rn is encoded as 0b1111, the instruction is UNPREDICTABLE.

```
[Rn]:<align>!
```

The address is contained in general-purpose register Rn. Rn is updated by this instruction:

```
Rn = Rn + transfer_size
```

Encoded as Rm = 0b1101. transfer_size is the number of bytes transferred by the instruction. This means that, after the instruction is executed, Rn points to the address in memory immediately following the last address loaded from or stored to.

- If Rn is encoded as 0b1111, the instruction is UNPREDICTABLE.

This addressing mode can also be written as:

```
[Rn]:<align>, #<transfer_size>
```

However, disassembly produces the [Rn]:<align>! form.

```
[Rn]:<align>, <Rm>
```

The address is contained in general-purpose register <Rn>. Rn is updated by this instruction:

```
Rn = Rn + Rm
```

Encoded as Rm = Rm. Rm must not be encoded as 0b1111 or 0b1101, the PC or the SP.

- If Rn is encoded as 0b1111, the instruction is UNPREDICTABLE.

In all cases, <align> specifies an alignment. Details are given in the individual instruction descriptions.

Previous versions of the manual used the @ character for alignment. So, for example, the first format in this section was shown as [Rn](@<align>). Both @ and : are supported. However, to ensure portability of code to assemblers that treat @ as a comment character, : is preferred.
F5.8 8, 16, and 32-bit transfers accessing the SIMD and floating-point register file

These are instructions that transfer data to or from registers in the SIMD and floating-point register file.

The T32 encoding of an Advanced SIMD and floating-point 8-bit, 16-bit, or 32-bit register data transfer instructions is:

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 T 1 1 1 0 A L 1 0 1 C B 1
```

The A32 encoding of an Advanced SIMD and floating-point 8-bit, 16-bit, or 32-bit register data transfer instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond 1 1 1 0 A L 1 0 1 C B 1
```

If \( T = 1 \) in the T32 encoding or \( \text{cond} == 0b1111 \) in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-23. Other encodings in this space are UNDEFINED.

These instructions are MRC and MCR instructions for coprocessors 10 and 11.

F5.9 **64-bit transfers accessing the SIMD and floating-point register file**

These are instructions that transfer data to or from the registers in the SIMD and floating-point register file.

The T32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:

```
   15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
   1  1  1 | T | 1  0  0 | 0 | D | 0
```

The A32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
   cond  1  1  0  0 | 0 | D | 0
```

If $T == 1$ in the T32 encoding or $cond == \text{0b1111}$ in the A32 encoding, the instruction is **UNDEFINED**.

Otherwise, the allocation of encodings in this space is shown in Table F5-24. Other encodings in this space are **UNDEFINED**.

These instructions are `MRRC` and `MCRR` instructions for coprocessors 10 and 11.

F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings
F5.9 64-bit transfers accessing the SIMD and floating-point register file
Chapter F6
ARMv8 Changes to the T32 and A32 Instruction Sets

This chapter summarizes the changes that ARMv8 makes to the T32 and A32 instruction sets. It contains the following section:

- The A32 and T32 instruction sets on page F6-2620.
- Partial deprecation of IT on page F6-2621.
- New A32 and T32 Load-Acquire/Store-Release instructions on page F6-2622.
- New A32 and T32 scalar floating-point instructions on page F6-2623.
- New A32 and T32 Advanced SIMD floating-point instructions on page F6-2626.
- New A32 and T32 instructions provided by the Cryptographic Extension on page F6-2628.
- New A32 and T32 System instructions on page F6-2629.
- CRC32 instructions on page F6-2631.
F6.1 The A32 and T32 instruction sets

This chapter describes the changes that ARMv8-A makes to the T32 and A32 instruction sets, compared to an ARMv7-A implementation that includes all of the following extensions:

- Multiprocessing Extensions.
- Large Physical Address Extension.
- Virtualization Extensions.
- Security Extensions.
- VFPv4.
- Advanced SIMDv2.

The implemented instructions are not affected by whether the ARMv8-A implementation includes either or both of EL2 and EL3.

ARMv8-A obsoletes the A32 SWP and SWPB instructions.

ARM deprecates any use of the following instructions. In ARMv8-A, privileged software can disable these instructions:

- A32 and T32 CP15 barriers CP15DSB, CP15ISB, and CP15DMB.
- A32 and T32 SETEND instruction.
- A subset of T32 IT instruction functionality, as described in Partial deprecation of IT on page F6-2621.

ARMv8-A adds new A32 and T32 instructions to align with some of the features introduced in the A64 instruction set. These are described in:

- Partial deprecation of IT on page F6-2621.
- New A32 and T32 Load-Acquire/Store-Release instructions on page F6-2622.
- New A32 and T32 scalar floating-point instructions on page F6-2623.
- New A32 and T32 Advanced SIMD floating-point instructions on page F6-2626.
- New A32 and T32 instructions provided by the Cryptographic Extension on page F6-2628.
- New A32 and T32 System instructions on page F6-2629.

Note

The existing A32 and T32 assembler syntax is unchanged from ARMv7 UAL. Where the syntax term <c> is used in this chapter, it represents a standard ARM condition code. Mnemonics that do not include <c> can not be conditionally executed.
F6.2 Partial deprecation of IT

ARMv8-A deprecates some uses of the T32 IT instruction. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. Table F6-1 shows the restricted set of 16-bit instructions that are not deprecated when used in conjunction with IT.

Table F6-1  Non-deprecated IT 16-bit conditional instructions

<table>
<thead>
<tr>
<th>Permitted 16-bit instructions</th>
<th>Class</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV, MVN</td>
<td>Move</td>
<td>Deprecated when Rm or Rd is the PC.</td>

<td>Logical</td>
<td>-</td>
</tr>
<tr>
<td>BX, BLX</td>
<td>Branch to register</td>
<td>Deprecated when Rm is the PC</td>
</tr>
</tbody>
</table>

**Note**

The ARMv7 IT instruction functionality remains available in order to execute ARMv7 T32 code. However, to verify conformance with the deprecation, a new control bit permits privileged software to disable the deprecated forms of the IT instruction, so that their use generates an Undefined Instruction exception. See HSCTRL.ITD.
F6.3 New A32 and T32 Load-Acquire/Store-Release instructions

The new Load-Acquire/Store-Release instructions must be naturally aligned. LDAEXD and STLEXD must be aligned to 8 bytes. An unaligned address causes an alignment fault. For more information about the ordering of Load-Acquire/Store-Release, see Load-Acquire, Store-Release on page E2-2449.

F6.3.1 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

Table F6-2 shows the new A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions.

</tbody>
</table>
F6.4 New A32 and T32 scalar floating-point instructions

This section describes the new A32 and T32 scalar floating-point instructions. It contains the following subsections:

- A32 and T32 floating-point conditional select.
- A32 and T32 floating-point minimum and maximum numeric.
- A32 and T32 floating-point to integer conversion.
- A32 and T32 floating-point conversion between half-precision and double-precision on page F6-2624.
- A32 and T32 floating-point round to integer on page F6-2624.

F6.4.1 A32 and T32 floating-point conditional select

The new VSEL instruction conditionally copies one of its two source registers to the destination register. For A32 it provides an alternative to a pair of conditional VMOV instructions, while for T32 it compensates for the partial deprecation of IT instruction described in Partial deprecation of IT on page F6-2621, since it does not require an IT prefix.

Table F6-4 shows the A32 and T32 floating-point conditional select instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSEL</td>
<td>Conditional select</td>
<td>VSELEQ, VSELGE, VSELGT, VSELVS on page F8-3721</td>
</tr>
</tbody>
</table>

F6.4.2 A32 and T32 floating-point minimum and maximum numeric

The new VMAXNM and VMINNM instructions implement the minNum(x, y) and maxNum(x, y) operations defined by the IEEE754-2008 standard. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to VFP VMAX and VMIN. These instructions cannot be conditionally executed.

Table F6-5 shows the A32 and T32 floating-point minNum and maxNum instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMAXNM</td>
<td>Single-precision maxNum (scalar)</td>
<td>VMAXNM on page F8-3503</td>
</tr>
<tr>
<td>VMINNM</td>
<td>Double-precision minNum (scalar)</td>
<td>VMINNM on page F8-3510</td>
</tr>
</tbody>
</table>

F6.4.3 A32 and T32 floating-point to integer conversion

These new instructions extend the ARMv7 VFP VCVT instructions by providing four additional explicit rounding modes. The instruction syntax is VCVTr, where r selects the rounding mode as follows:

- N: Round to Nearest.
- A: Round to Nearest with Ties to Away.
- P: Round towards Plus Infinity.
- M: Round towards Minus Infinity.

The rounding modes are defined by the IEEE 754 standards, see Floating-point standards, and terminology on page A1-50.

These instructions cannot be conditionally executed.
F6.4 New A32 and T32 scalar floating-point instructions

Table F6-6 shows the A32 and T32 FP to integer conversion instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>VCVTA</td>
<td>Convert floating-point to integer with Round to Nearest with Ties to Away</td>
<td>VCVTA (floating-point) on page F8-3407</td>
</tr>
<tr>
<td>VCVTM</td>

</tr>
<tr>
<td>VCVTP</td>
<td>Convert floating-point to integer with Round towards Plus Infinity</td>
<td>VCVTP (floating-point) on page F8-3422</td>
</tr>
</tbody>
</table>

**F6.4.4 A32 and T32 floating-point conversion between half-precision and double-precision**

The VFP VCVTT and VCVTB instructions are extended to permit direct conversion between half-precision and double-precision floating-point as a single operation, preventing double rounding errors. The syntax term <y> in Table F6-7 is either T, top half, and ṛ, bottom half.

Table F6-7 shows the A32 and T32 instructions to convert between half-precision and double-precision floating-point values.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>

</tr>
<tr>
<td>VCVTT</td>
<td>Floating-point convert double-precision to single-precision</td>
<td>VCVTT on page F8-3427</td>
</tr>
</tbody>
</table>

**F6.4.5 A32 and T32 floating-point round to integer**

The new round to integer instructions round a floating-point value to the nearest integer floating-point value of the same size. The floating-point exceptions that can be raised by these instructions are the Invalid operation, for a signaling NaN input, or Input Denormal, for a denormal input when flush-to-zero mode is enabled. For VRINTX only an Inexact exception can be raised if the result is numeric and does not have the same numerical value as the source. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal floating-point arithmetic.

The instruction syntax is VRINT<e>, where <e> selects the rounding mode as follows:

- N  Round to Nearest.
- A  Round to Nearest with Ties to Away.
- P  Round towards Plus Infinity.
- M  Round towards Minus Infinity.
- Z  Round towards Zero.
- R  FPSCR rounding mode.
- X  FPSCR rounding mode, signaling inexactness.

When <e> is R, X, or Z, the round to integer l instruction can be conditionally executed. The remaining round to integer instructions must be unconditional.

Table F6-8 on page F6-2625 shows the A32 and T32 round to integer instructions.

F6.5 **New A32 and T32 Advanced SIMD floating-point instructions**

The AArch32 Advanced SIMD instructions support only single-precision, 32-bit, floating-point data types, with fixed operating modes of Round to Nearest, Default NaN, and Flush-to-Zero. However, they are extended by the addition of the instructions described in the following subsections:

- **A32 and T32 floating-point minimum and maximum numeric.**
- **A32 and T32 floating-point conversion.**
- **A32 and T32 floating-point round to integral on page F6-2627.**

F6.5.1 **A32 and T32 floating-point minimum and maximum numeric**

Vector forms of the new \texttt{VMAXNM} and \texttt{VMINNM} instructions are described in \textit{A32 and T32 floating-point minimum and maximum numeric} on page F6-2623.

Table F6-9 shows the A32 and T32 floating-point minNum/maxNum instructions.

<td>\texttt{VMINNM} on page F6-3510</td>
</tr>
</tbody>
</table>

F6.5.2 **A32 and T32 floating-point conversion**

Vector forms of the floating-point to integer conversion instructions are described in \textit{A32 and T32 floating-point to integer conversion} on page F6-2623. The instruction syntax is \texttt{VCVTr}, where \texttt{r} selects the rounding mode as follows:

- \texttt{N}  Round to Nearest.
- \texttt{A}  Round to Nearest with Ties to Away.
- \texttt{P}  Round towards Plus Infinity.
- \texttt{M}  Round towards Minus Infinity.

The rounding modes are defined by the IEEE 754 standards, see \textit{Floating-point standards, and terminology} on page A1-50.

F6.5.3 A32 and T32 floating-point round to integral

Vector forms of the floating-point rounding instructions are described in A32 and T32 floating-point round to integer on page F6-2624. The instruction syntax is VRINT\(r\), where \(r\) selects the rounding mode as follows:

- **N**: Round to Nearest.
- **A**: Round Nearest with Ties to Away.
- **P**: Round towards Plus Infinity.
- **M**: Round towards Minus Infinity.
- **Z**: Round towards Zero.
- **X**: Round to Nearest, signaling inexactness.

The rounding modes are defined by the IEEE 754 standards, see Floating-point standards, and terminology on page A1-50.

Table F6-11 shows the A32 and T32 floating-point round to integral instructions.

F6.7.3  TLB Maintenance

TLB maintenance instructions that are only required to apply to the last level translation table walk of the first stage of translation are added to A32 and T32 as shown in Table F6-15. For more information see Translation Lookaside Buffers (TLBs) on page G4-4132 and TLB maintenance requirements on page G4-4135.

</table>
A32 and T32 include TLB maintenance instructions that must apply to individual entries from stage 2 TLB structures, that hold IPA to PA translations. These are consistent with the A64 TLBI system instructions described in New A32 and T32 System instructions on page F6-2629. The relation between the A32 and T32 instructions and the A64 instructions is shown in Table F6-16.

F6 ARMv8 Changes to the T32 and A32 Instruction Sets
F6.8 CRC32 instructions
Chapter F7
T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Alphabetical list of T32 and A32 base instruction set instructions on page F7-2634.*
- *Encoding and use of Banked register transfer instructions on page F7-3266.*
F7.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see Format of instruction descriptions on page F2-2512.

This section is formatted so that each instruction description starts on a new page.
F7.1.1 ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

if \(d == 15\) || \(n == 15\) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<Rd>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<Rn>\). ARM deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<Rn>\).

\(<Rn>\) For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

\(<\text{const}>\) For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

For encoding T1: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

**Operation for all encodings**

if ConditionPassed() then

EncodingSpecificOperations();

\((\text{result, nzcv}) = \text{AddWithCarry}(R[n], \text{imm32}, \text{PSTATE}.C)\);

if \(d == 15\) then

if setflags then

ALUExceptionReturn(result);
else

ALUWritePC(result);
else

\(R[d] = \text{result};\)

if setflags then

PSTATE.<N,Z,C,V> = nzcv;
F7.1.2 ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2386.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<\text{current\_mode}>\).
  - The PE checks SPSR_\(<\text{current\_mode}>\) for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

• ADC, rotate right with extend variant

Applies when \(S = 0 \&\& \text{imm5} = 00000 \&\& \text{type} = 11\).

\(ADC\{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm>, RRX\)

• ADC, shift or rotate by value variant

Applies when \(S = 1 \&\& \text{imm5} = 00000 \&\& \text{type} = 11\).

\(ADC\{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm> \{<shift> \#<amount>\}\)

• ADCS, rotate right with extend variant

Applies when \(S = 0 \&\& \text{imm5} = 00000 \&\& \text{type} = 11\).

\(ADCS\{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm>, RRX\)

• ADCS, shift or rotate by value variant

Applies when \(S = 1 \&\& \text{imm5} = 00000 \&\& \text{type} = 11\).

\(ADCS\{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm> \{<shift> \#<amount>\}\)

• Decode for all variants of this encoding

Decode for all variants of this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<
See Standard assembler syntax fields on page F2-2516.

>
See Standard assembler syntax fields on page F2-2516.

<Rdn>
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount>
Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<cc> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<cc> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        ALUWritePC(result);
else
R[d] = result;
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
F7.1.3 ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

```
| 31 | 28|27 26 25 24|23 22 21 20|19 16|15 | 12|11 | 8 | 7 6 5 4 3 0 |
|----|----|-----------|----------|-----|----|----|----|----|----|----|----|----|----|----|
| !=1111 | 0 0 0 0 | 1 0 1 | S | Rn | Rd | Rs | 0 | type | 1 | Rm |

Flag setting variant

Applies when $S = 1$.

$\text{ADCS}^{<c>}{<q>}{<Rd>,} <Rn>, <Rm>, <\text{type}> <Rs>$

Not flag setting variant

Applies when $S = 0$.

$\text{ADC}^{<c>}{<q>}{<Rd>,} <Rn>, <Rm>, <\text{type}> <Rs>$

Decode for all variants of this encoding

```
d = \text{UInt}(Rd); n = \text{UInt}(Rn); m = \text{UInt}(Rm); s = \text{UInt}(Rs);
setflags = (S == '1'); shift_t = \text{DecodeRegShift}(\text{type});
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F2-2516.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<\text{type}>` Is the type of shift to be applied to the second source register, encoded in the "\text{type}" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11
- `<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
  R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
F7.1.4 ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The ADDS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<\text{current\_mode}>\).
  - The PE checks SPSR_\(<\text{current\_mode} >\) for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if d == 15 then UNPREDICTABLE;   // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRANDED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<c> See Standard assembler syntax fields on page F2-2516.

<q> See Standard assembler syntax fields on page F2-2516.

<Rdn> Is the general-purpose source and destination register, encoded in the "Rdn" field.

<imm8> Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

• For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

• For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of this instruction.

For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate). If the PC is used, see ADR.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate).

<imm3> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the ADDW syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

Operation for all encodings

if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    if d == 15 then          // Can only occur for A32 encoding
      if setflags then
        ALUExceptionReturn(result);
      else
        // ARMv8-A removes UNPREDICTABLE for R13
      
    else
      // ARMv8-A removes UNPREDICTABLE for R13
  
end
ALUWritePC(result);
else
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
F7.1.5 ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386*.

- The ADDS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state on page G1-3861*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

```

\[
\text{if (d == 15 \&\& !setflags) || n == 15 || m == 15 \text{ then UNPREDICTABLE};}
\]

// ARMv8-A removes UNPREDICTABLE for R13

**Notes for all encodings**

For information about the constrained UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- \(\langle c\rangle\): See Standard assembler syntax fields on page F2-2516.
- \(\langle p\rangle\): See Standard assembler syntax fields on page F2-2516.
- \(\langle Rdn\rangle\): Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386. The assembler language allows \(\langle Rdn\rangle\) to be specified once or twice in the assembler syntax. When used inside an IT block, and \(\langle Rdn\rangle\) and \(\langle Rm\rangle\) are in the range R0 to R7, \(\langle Rdn\rangle\) must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when \(\langle Rdn\rangle\) is specified once or twice.

- \(\langle Rd\rangle\): For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(\langle Rn\rangle\). If the PC is used:
  - For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_\(\langle current\_mode\rangle\). ARM deprecates use of this instruction.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. When used inside an IT block, \(\langle Rd\rangle\) must be specified. When used outside an IT block, \(\langle Rd\rangle\) is optional, and:

- If omitted, this register is the same as \(\langle Rn\rangle\).
- If present, encoding T1 is preferred to encoding T2.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(\langle Rn\rangle\).

- \(\langle Rn\rangle\): For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see ADD, ADDS (SP plus register).

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus register).

- \(\langle Rm\rangle\): For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have
the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> =
LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Inside an IT block, if ADD<cr> <Rs>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using
encoding T2 as though ADD<cr> <Rs>, <Rn> had been written. To prevent this happening, use the .W qualifier.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F7.1.6   ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the
destination register, and can optionally update the condition flags based on the result.

\]

\[
\text{if } d == 15 || n == 15 || m == 15 || s == 15 \text{ then UNPREDICTABLE;}
\]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on
UNPREDICTABLE behaviors.

Assembler symbols

\(<c>\)   See Standard assembler syntax fields on page F2-2516.
\(<q>\)   See Standard assembler syntax fields on page F2-2516.
\(<Rd>\)   Is the general-purpose destination register, encoded in the "Rd" field.
\(<Rn>\)   Is the first general-purpose source register, encoded in the "Rn" field.
\(<Rm>\)   Is the second general-purpose source register, encoded in the "Rm" field.
\(<type>\)  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have
the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>type = 00</td>
</tr>
<tr>
<td>LSR</td>
<td>type = 01</td>
</tr>
<tr>
<td>ASR</td>
<td>type = 10</td>
</tr>
<tr>
<td>ROR</td>
<td>type = 11</td>
</tr>
</tbody>
</table>

\(<Rs>\)   Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in
the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
F7.1.7 ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2386.
- The ADDS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

#### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<c>  See Standard assembler syntax fields on page F2-2516.

<q>  See Standard assembler syntax fields on page F2-2516.

<imm7>  Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

<Rd>  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:
  •  For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  •  For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm8>  Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

<imm12>  Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const>  For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  (result, nzcv) = AddWithCarry(SP, imm32, '0');
  if d == 15 then          // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.<N,Z,C,V> = nzcv;
F7.1.8   ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

• The ADD variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

• The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
  — The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  — The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  — The instruction is UNDEFINED in Hyp mode.
  — The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

```
<c>       See Standard assembler syntax fields on page F2-2516.
<q>       See Standard assembler syntax fields on page F2-2516.
<Rdm>     Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
<Rd>      For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:
            • For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
            • For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.
<Rm>      For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.
<shift>   Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
            LSL       when type = 00
            LSR       when type = 01
            ASR       when type = 10
            ROR       when type = 11
<amount>  Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
```
(result, nzcv) = AddWithCarry(SP, shifted, '0');
if d == 15 then
  if setflags then
    ALUExceptionReturn(result);
  else
    ALUWritePC(result);
else
  R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
### F7.1.9 ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias.

This instruction is an alias of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The description of ADR gives the operational pseudocode for this instruction.

**T3 variant**

ADDW{<c>}{<q>} <Rd>, PC, #<imm12> can be represented in T1

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

ADD{<c>}{<q>} <Rd>, PC, #<imm12>
is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`: See *Standard assembler syntax fields* on page F2-2516.
- `<q>`: See *Standard assembler syntax fields* on page F2-2516.
- `<Rd>`: For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2386.
  
  For encoding T1 and T3: is the general-purpose destination register, encoded in the "Rd" field.

- `<label>`: For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(\text{PC}, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset. If the offset is negative, encoding A2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions* on page F4-2569.
  
  For encoding T1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(\text{PC}, 4)` value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.
  
  For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(\text{PC}, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset. If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are 0-4095.

- `<imm8>`: Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as `<imm8>/4`.

- `<imm12>`: Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

- `<const>`: An immediate value. See *Modified immediate constants in A32 instructions* on page F4-2569 for the range of values.

**Operation for all encodings**

The description of ADR gives the operational pseudocode for this instruction.
F7.1.10   ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the aliases ADD (immediate, to PC) and SUB (immediate, from PC). See the Alias conditions on page F7-2663 table for details of when each alias is preferred.

<td>A2</td>
</tr>
</tbody>
</table>

**Assembler symbols**

- `<c>`
  - See Standard assembler syntax fields on page F2-2516.
- `<q>`
  - See Standard assembler syntax fields on page F2-2516.
- `<Rd>`
  - For encoding A1 and A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For encoding T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.
- `<label>`
  - For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(\text{PC}, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with \text{imm32} equal to the offset. If the offset is negative, encoding A2 is used, with \text{imm32} equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of \text{imm32}. Permitted values of the size of the offset are any of the constants described in Modified immediate constants in A32 instructions on page F4-2569.
For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the \texttt{Align(PC, 4)} value of the \texttt{ADR} instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the \texttt{Align(PC, 4)} value of the \texttt{ADR} instruction to this label. If the offset is zero or positive, encoding T3 is used, with \texttt{imm32} equal to the offset. If the offset is negative, encoding T2 is used, with \texttt{imm32} equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of \texttt{imm32}. Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see \textit{Use of labels in UAL instruction syntax} on page F1-2479.

**Operation for all encodings**

```c
if \texttt{ConditionPassed()} then
    EncodingSpecificOperations();
    result = if add then \texttt{(Align(PC,4) + imm32)} else \texttt{(Align(PC,4) - imm32)};
    if \texttt{d == 15} then // Can only occur for A32 encodings
        \texttt{ALUWritePC(result)};
    else
        \texttt{R[d] = result;}
```
F7.1.11 AND, ANDS (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2516.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. ARM deprecates using the PC as the destination register, but if the PC is used:
  - For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR._<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

- `<Rn>` For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used.
  For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

- `<const>` For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.
  For encoding T1: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        else
            R[d] = result;
            if setflags then
                PSTATE.N = result<31>;
                PSTATE.Z = IsZeroBit(result);
                PSTATE.C = carry;
                // PSTATE.V unchanged
F7.1.12 AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<\text{current\_mode}>\).
  - The PE checks SPSR_\(<\text{current\_mode}>\) for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if (d == 15 \& \& !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<\text{Rdn}>\) Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

\(<\text{Rd}>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<\text{Rn}>\). ARM deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<\text{Rn}>\).

\(<\text{Rn}>\) For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

\(<\text{Rm}>\) For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

\(<\text{shift}>\) Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

\(<\text{amount}>\) Is the shift amount, in the range 1 to 31 (when \(<\text{shift}>\) = LSL or ROR) or 1 to 32 (when \(<\text{shift}>\) = LSR or ASR) encoded in the "imm5" field as \(<\text{amount}>\) modulo 32.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.
- Inside an IT block, if AND<-> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<-> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] AND shifted;
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
  if setflags then
```

PSTATE.N = result<31>;
PSTATE.Z = IsZeroBit(result);
PSTATE.C = carry;
// PSTATE.V unchanged
F7.1.13   AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

|     |     |     |     |     | 10 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

Not flag setting variant

Applies when \( S = 0 \).

\text{AND}\{<c>\}{<q>} \{<Rd>,} <Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

\( d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ m = \text{UInt}(Rm); \ s = \text{UInt}(Rs); \)

\( \text{setflags} = (S == '1'); \ \text{shift}_t = \text{DecodeRegShift}(\text{type}); \)

\( \text{if} \ d == 15 || n == 15 || m == 15 || s == 15 \ \text{then} \ \text{UNPREDICTABLE;} \)

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\) Is the first general-purpose source register, encoded in the "Rn" field.

\(<Rm>\) Is the second general-purpose source register, encoded in the "Rm" field.

\(<\text{type}>\) Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

\(<Rs>\) Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
F7.1.14 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F7.1.16 ASRS (immediate)

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Related encodings: Brances and miscellaneous control on page F3-2543.

Assembler symbols

<c> For encoding A1, T2 and T4: see Standard assembler syntax fields on page F2-2516.
For encoding T1: see Standard assembler syntax fields on page F2-2516. Must not be AL or omitted.
For encoding T3: see Standard assembler syntax fields on page F2-2516. c must not be AL or omitted.

<q> See Standard assembler syntax fields on page F2-2516.

<label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –256 to 254.
For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –2048 to 2046.
For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –1048576 to 1048574.
For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets \texttt{imm32} to that offset. Permitted offsets are even numbers in the range \(-16777216\) to \(16777214\).

        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
F7.1.21 BIC, BICS (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<current\_mode>\).
  - The PE checks SPSR_\(<current\_mode>\) for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if d == 15 || n == 15 then UNPREDICTABLE;  // ARMv8-A removes UNPREDICTABLE for R13
```

**Notes for all encodings**

For information about the CONstrained UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2516.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. ARM deprecates using the PC as the destination register, but if the PC is used:
  - For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

- `<Rn>` For encoding A1: is the general-purpose source register, encoded in the "Rn" field. For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

- `<const>` For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.
  
  For encoding T1: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```
F7.1.22 BIC, BICS (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<c>
See Standard assembler syntax fields on page F2-2516.

<q>
See Standard assembler syntax fields on page F2-2516.

<Rdn>
Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

- For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount>
Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] AND NOT(shifted);
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged
### F7.1.23  BIC, BICS (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

#### A1

![Register encoding](image)

**Flag setting variant**

Applies when $S = 1$.

```assembly
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <type> <Rs>
```

**Not flag setting variant**

Applies when $S = 0$.

```assembly
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <type> <Rs>
```

**Decode for all variants of this encoding**

```c
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

**Notes for all encodings**

For information about the CONstrained UNPredicable behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<q>`: See Standard assembler syntax fields on page F2-2516.
- `<Rd>`: Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>`: Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>`: Is the second general-purpose source register, encoded in the "Rm" field.
- `<type>`: Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11
- `<Rs>`: Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
F7.1.24   BKPT

Breakpoint causes a Software Breakpoint Instruction exception.

Breakpoint is always unconditional, even when inside an IT block.

<c>
For encoding A1, T1 and T2: see Standard assembler syntax fields on page F2-2516.
For encoding A2: see Standard assembler syntax fields on page F2-2516. <c> must be AL or omitted.

<q>
See Standard assembler syntax fields on page F2-2516.

<label>
For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
For encoding A2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –33554432 to 33554430.
For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.
For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

**Operation for all encodings**

if ConditionPassed() then

See Standard assembler syntax fields on page F2-2516.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<Rm>
For encoding A1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T1: is the general-purpose source register, encoded in the "Rm" field. Its number must be encoded twice.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
F7.1.33 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

**A1**

\[
\begin{array}{cccccccccccccccccccc}
| 31 & 28|27 & 26 & 25 & 24|23 & 22 & 21 & 20|19 & 16|15 & 14 & 13 & 12|11 | 0 | 0 | 0 | 0 |
\end{array}
\]

\[
\text{cond} = 1111, \quad \text{Rn}, \quad \text{imm12}
\]

**A1 variant**

CMN{<c>}{<q>} <Rn>, #<const>

**Decode for this encoding**

**Assembler symbols**

<

See Standard assembler syntax fields on page F2-2516.

>

See Standard assembler syntax fields on page F2-2516.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T1, T2 and T3: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1, T2 and T3: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift</th>
<th>When Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>type = 00</td>
</tr>
<tr>
<td>LSR</td>
<td>type = 01</td>
</tr>
<tr>
<td>ASR</td>
<td>type = 10</td>
</tr>
<tr>
<td>ROR</td>
<td>type = 11</td>
</tr>
</tbody>
</table>

<amount>
Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    PSTATE.<N,Z,C,V> = nzcv;
F7.1.38  CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

\end{align*}
\]
Notes for all encodings

Hint instructions: In encoding T2, if the imod field is 00 and the M bit is 0, a hint instruction is encoded. To determine which hint instruction, see Change PE State, and hints on page F3-2544.

For information about the CONstrained UNPREDICTable behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTable behaviors, and particularly CPS (T32) on page J1-5418 and CPS (A32) on page J1-5417.

Assembler symbols

<q>
See Standard assembler syntax fields on page F2-2516.

<iflags>
Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

a Sets the A bit in the instruction, causing the specified effect on PSTATE.A, the asynchronous abort mask bit.

i Sets the I bit in the instruction, causing the specified effect on PSTATE.I, the IRQ interrupt mask bit.

f Sets the F bit in the instruction, causing the specified effect on PSTATE.F, the FIQ interrupt mask bit.

<mode>
Is the number of the mode to change to, in the range 0 to 31, encoded in the "mode" field.

Operation for all encodings

```plaintext
if CurrentInstrSet() == InstrSet_A32 then
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then
            if affectA then PSTATE.A = '0';
            if affectI then PSTATE.I = '0';
            if affectF then PSTATE.F = '0';
        if disable then
            if affectA then PSTATE.A = '1';
            if affectI then PSTATE.I = '1';
            if affectF then PSTATE.F = '1';
        if changemode then
            // WriteMode will set PSTATE.IL if 'mode' is not legal.
            AArch32.WriteMode(mode);
    else
        EncodingSpecificOperations();
        if PSTATE.EL != EL0 then
            if enable then
                if affectA then PSTATE.A = '0';
                if affectI then PSTATE.I = '0';
                if affectF then PSTATE.F = '0';
            if disable then
                if affectA then PSTATE.A = '1';
                if affectI then PSTATE.I = '1';
                if affectF then PSTATE.F = '1';
            if changemode then
                // WriteMode will set PSTATE.IL if 'mode' is not legal.
                AArch32.WriteMode(mode);
```
F7.1.40  **CRC32**

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It is an optional instruction. It takes an input CRC value in the first source operand, and performs a CRC on an input value in the second source operand that can be 8, 16, or 32 bits, and returns the output CRC value. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

--- **Note** ---

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

#### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

#### Assembler symbols

- `<c>`  See Standard assembler syntax fields on page F2-2516.
- `<q>`  See Standard assembler syntax fields on page F2-2516.
- `<option>` Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "option" field.

#### Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Debug(option);
F7.1.43   DCPS1, DCPS2, DCPS3

Debug Change PE State allows the debugger to move the PE into a higher Exception Level or to a specific mode at the current Exception Level.

These instructions are always UNDEFINED in Non-debug state.

DCPS1 targets EL1 and:

- If EL1 is using AArch32, the PE enters SVC mode. If EL3 is using AArch32, Secure SVC is an EL3 mode. This means DCPS1 causes the PE to enter EL3.
- If EL1 is using AArch64, the PE enters EL1h, and executes future instructions as A64 instructions.

DCPS2 targets EL2 and:

- If EL2 is using AArch32, the PE enters Hyp mode.
- If EL2 is using AArch64, the PE enters EL2h, and executes future instructions as A64 instructions.

DCPS3 targets EL3 and:

- If EL3 is using AArch32, the PE enters Monitor mode.
- If EL3 is using AArch64, the PE enters EL3h, and executes future instructions as A64 instructions.

For more information on the operation of these instructions, see *DCPS on page H2-5003*.

**Decode for this encoding**

// No additional decoding required

#### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

#### Assembler symbols

- `<c>` For encoding A1: see Standard assembler syntax fields on page F2-2516. Must be AL or omitted.
- `<q>` For encoding T1: see Standard assembler syntax fields on page F2-2516.
- `<option>` See Standard assembler syntax fields on page F2-2516.

**<option>** Specifies an optional limitation on the barrier operation. Values are:

- **SY** Full system is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Can be omitted. This option is referred to as the full system DMB. Encoded as option = 0b1111.

- **ST** Full system is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. SYST is a synonym for ST. Encoded as option = 0b1110.

- **LD** Full system is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b1101.
ISH Inner Shareable is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b1011.

ISHST Inner Shareable is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b1010.

ISHLD Inner Shareable is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b1001.

NSH Non-shareable is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0111.

NSHST Non-shareable is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0110.

NSHLD Non-shareable is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b0101.

OSH Outer Shareable is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior.

--- Note ---

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

--- Operation for all encodings ---

```

T1 variant

DSB{<c>}{<q>} {<option>}

**Decode for this encoding**

// No additional decoding required

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>`  For encoding A1: see Standard assembler syntax fields on page F2-2516. Must be `AL` or omitted.
  
  For encoding T1: see Standard assembler syntax fields on page F2-2516.

- `<q>`  See Standard assembler syntax fields on page F2-2516.

- `<option>`  Specifies an optional limitation on the barrier operation. Values are:
  
  - **SY**  Full system is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Can be omitted. This option is referred to as the full system DMB. Encoded as option = `0b1111`.
  
  - **ST**  Full system is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. SYST is a synonym for ST. Encoded as option = `0b1110`.
  
  - **LD**  Full system is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = `0b1101`.  

ISH  Inner Shareable is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b1011.

ISHST Inner Shareable is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b1010.

ISHLD Inner Shareable is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b1001.

NSH Non-shareable is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0111.

NSHST Non-shareable is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0110.

NSHLD Non-shareable is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b0101.

OSH Outer Shareable is the required shareability domain, reads and writes are the required access types in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type in both Group A on page E2-2447 and Group B on page E2-2447. Encoded as option = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type in Group A on page E2-2447, and reads and writes are the required access types in Group B on page E2-2447. Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior.

Note
The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

Operation for all encodings

    domain = MBRqDomain_InnerShareable;
  DataSynchronizationBarrier(domain, types);
F7.1.46   EOR, EORS (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<c>  See Standard assembler syntax fields on page F2-2516.

<r>  See Standard assembler syntax fields on page F2-2516.

<Rdn>  Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd>  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:
  • For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  • For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>  For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm>  For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11

<amount>  Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

In T32 assembly:
  • Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written.
  • Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_CCR[m], shift_t, shift_n, PSTATE.C);
  result = R[n] EOR shifted;
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
  if setflags then
PSTATE.N = result<31>;
PSTATE.Z = IsZeroBit(result);
PSTATE.C = carry;
// PSTATE.V unchanged
F7.1.48 EOR, EORS (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a
register-shifted register value. It writes the result to the destination register, and can optionally update the condition
flags based on the result.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix J1 Architectural Constraints on
UNPREDICTABLE behaviors.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\) Is the first general-purpose source register, encoded in the "Rn" field.

\(<Rm>\) Is the second general-purpose source register, encoded in the "Rm" field.

\(<\text{type}>\) Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have
the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

\(<Rs>\) Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in
the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
F7.1.49 ERET

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores PSTATE from SPSR_<current_mode>.

The register holding the preferred return address is:

- ELR_hyp, when executing in Hyp mode.
- LR, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.

Exception Return is CONSTRAINED UNPREDICTABLE in User mode and System mode.

In Debug state, the T1 encoding of ERET is decoded as DRPS.

// imm6 is for assembly/disassembly only and ignored by hardware

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors, and particularly \text{HLT} on page J1-5374.

Assembler symbols

\(<q>\) See \textit{Standard assembler syntax fields} on page F2-2516. An HLT instruction must be unconditional.

\(<\text{imm}>\) For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

For encoding T1: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the "imm6" field. This value is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation for all encodings

EncodingSpecificOperations();
Halt(DebugHalt_HaltInstruction);
F7.1.51   HVC

Hypervisor Call causes a Hypervisor Call exception. For more information see Hypervisor Call (HVC) exception on page G1-3883. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is:

- UNDEFINED in Secure state, and in User mode in Non-secure state.
- When SCR.HCE is set to 0, UNDEFINED in Non-secure EL1 modes and CONSTRAINED UNPREDICTABLE in Hyp mode.

On executing an HVC instruction, the HSR reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see Use of the HSR on page G4-4177.

if hvc_enable == '0' then
    UNDEFINED;
else
    AArch32.CallHypervisor(imm16);
```
F7.1.52   ISB

Instruction Synchronization Barrier flushes the pipeline in the PE, so that all instructions following the ISB are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the ISB instruction are visible to the instructions fetched after the ISB. Context changing operations include changing the Address Space Identifier (ASID), TLB maintenance instructions, branch predictor maintenance operations, and all changes to the System registers.

In addition, any branches that appear in program order after the ISB instruction are written into the branch prediction logic with the context that is visible after the ISB instruction. This is needed to ensure correct execution of the instruction stream.

For more information, see Instruction Synchronization Barrier (ISB) on page E2-2447.

Assembler symbols

<|>        For encoding A1: see Standard assembler syntax fields on page F2-2516. Must be AL or omitted.
For encoding T1: see Standard assembler syntax fields on page F2-2516.

<|>        See Standard assembler syntax fields on page F2-2516.

<|>        Specifies an optional limitation on the barrier operation. Values are:
SY        Full system barrier operation, encoded as option = 0b1111. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
F7.1.53   IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than CMP, CMN and TST, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores ITSTATE to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

See also Conditional instructions on page F1-2479 and Conditional execution on page F2-2517.

T1

```
15 14 13 12|11 10 9 8 |7 4 |3 0 |
  1 0 1 1 1 1 1 1 | firstcond | l=0000 | mask
```

T1 variant

IT{<x>{<y>{<z>}}}{<q>} <cond>

Decode for this encoding

- if mask == '0000' then SEE "Related encodings";
- if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
- if InITBlock() then UNPREDICTABLE;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly IT on page J1-5374.

Related encodings: If-Then, and hints on page F3-2537.

Assembler symbols

- <x> The condition for the second instruction in the IT block. If omitted, the "mask" field is set to 0b1000.
  If present it is encoded in the "mask[3]" field:
    T   firstcond[0]
    E   NOT firstcond[0]

- <y> The condition for the third instruction in the IT block. If omitted and <x> is present, the "mask[2:0]"
  field is set to 0b10. If <y> is present it is encoded in the "mask[2]" field:
    T   firstcond[0]
    E   NOT firstcond[0]

- <z> The condition for the fourth instruction in the IT block. If omitted and <y> is present, the "mask[1:0]"
  field is set to 0b10. If <z> is present, the "mask[0]" field is set to 1, and it is encoded in the "mask[1]"
  field:
    T   firstcond[0]
\( \text{E} \quad \text{NOT firstcond[0]} \)

\(<\text{cond}>\) See Standard assembler syntax fields on page F2-2516.

\(<\text{cond}>\) The condition for the first instruction in the IT block, encoded in the "firstcond" field. See Table F2-1 on page F2-2517 for the range of conditions available, and the encodings.

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See Conditional instructions on page F1-2479.

**Operation**

```c
EncodingSpecificOperations();
AArch32.CheckITEnabled(mask);
PSTATE.IT<7:0> = firstcond:mask;
```

F7.1.61 LDC, LDC2 (immediate)

Load Coprocessor (immediate) loads data from consecutive memory addresses to a conceptual coprocessor.

This is a generic coprocessor instruction. The coproc field identifies the target conceptual coprocessor. This must be one of CP10, CP11, CP14, or CP15, and for these CP values, this manual defines the imm8, CRd, and D field values that are valid LDC and LDC2 instructions. Other encodings are UNDEFINED. For more information see Conceptual coprocessor support on page E1-2422 and General behavior of System registers on page G4-4190.

In an implementation that includes EL2, the permitted LDC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general CP14 accesses to debug registers on page G1-3942.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

Advanced SIMD and floating-point: Advanced SIMD and floating-point register load/store instructions on page F5-2612.

Assembler symbols

If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.

For encoding A1, T1 and T2: see Standard assembler syntax fields on page F2-2516.
For encoding A2: see Standard assembler syntax fields on page F2-2516. <c> must be AL or omitted.

See Standard assembler syntax fields on page F2-2516.
<coproc>  Is the name of the coprocessor, encoded in the "coproc" field. The valid coprocessor names are p10, p11, p14, and p15.

<CRd>  Is the coprocessor register to be transferred, encoded in the "CRd" field.

<Rn>  Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see LDC, LDC2 (literal).

<option>  Is a coprocessor option, in the range 0 to 255 enclosed in {}, encoded in the "imm8" field.

+/-  Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
-  when U = 0
+  when U = 1

<imm>  Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

**Operation for all encodings**

```cpp
if ConditionPassed() then
    EncodingSpecificOperations();
    Coproc_CheckInstr(cp, ThisInstr());
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    repeat
        Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
        address = address + 4;
    until Coproc_DoneLoading(cp, ThisInstr());
    if wback then R[n] = offset_addr;
```
F7.1.62   LDC, LDC2 (literal)

Load Coprocessor (literal) loads data from consecutive memory addresses to a conceptual coprocessor.

This is a generic coprocessor instruction. The coproc field identifies the target conceptual coprocessor. This must be one of CP10, CP11, CP14, or CP15, and for these CP values, this manual defines the imm8, Crd, and D field values that are valid LDC and LDC2 instructions. Other encodings are UNDEFINED. For more information see Conceptual coprocessor support on page E1-2422 and General behavior of System registers on page G4-4190.

In an implementation that includes EL2, the permitted LDC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general CP14 accesses to debug registers on page G1-3942.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDC/LDC2 (literal) on page J1-5374.

Advanced SIMD and floating-point: Advanced SIMD and floating-point register load/store instructions on page F5-2612.

Assembler symbols

L
If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.

<e>
For encoding A1, T1 and T2: see Standard assembler syntax fields on page F2-2516.
For encoding A2: see Standard assembler syntax fields on page F2-2516. <e> must be AL or omitted.

<q>
See Standard assembler syntax fields on page F2-2516.
<coproc> Is the name of the coprocessor, encoded in the "coproc" field. The valid coprocessor names are p10, p11, p14, and p15.

<CRd> Is the coprocessor register to be transferred, encoded in the "CRd" field.

<option> Is a coprocessor option, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1). If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    Coproc_CheckInstr(cp, ThisInstr());
    offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    address = if index then offset_addr else Align(PC,4);
    repeat
        Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
        address = address + 4;
    until Coproc_DoneLoading(cp, ThisInstr());
```
F7.1.63  LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

Related system instructions are LDM (User registers) and LDM (exception return).

This instruction is used by the alias POP (multiple registers). See the Alias conditions on page F7-2772 table for details of when each alias is preferred.

Assembler symbols

IA  
Is an optional suffix for the Increment After form.

<c>  
See Standard assembler syntax fields on page F2-2516.

<q>  
See Standard assembler syntax fields on page F2-2516.

<Rn>  
Is the general-purpose base register, encoded in the "Rn" field.

!  
For encoding A1 and T2: the address adjusted by the size of the data loaded is written back to the
base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
For encoding T1: the address adjusted by the size of the data loaded is written back to the base
register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

<registers>  
For encoding A1: is a list of one or more registers to be loaded, separated by commas and
surrounded by { and }. The PC can be in the list. ARM deprecates using these instructions with both
the LR and the PC in the list.
For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.
The registers in the list must be in the range R0-R7, encoded in the "register_list" field.
For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.
The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain
one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.
If the PC is in the list:
• The LR must not be in the list.
• The instruction must be either outside any IT block, or the last instruction in an IT block.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
        if registers<15> == '1' then
            LoadWritePC(MemA[address,4]);
        if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
F7.1.64  LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The SPSR of the current mode is copied to the CPSR. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

Load Multiple (exception return) is:

• UNDEFINED in Hyp mode.
• UNPREDICTABLE in debug state, and in User mode and System mode.

wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDM (exception return) on page J1-5419.

Assembler symbols

<amode> is one of:

DA  Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
FA  Full Ascending. For this instruction, a synonym for DA.
DB  Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
EA  Empty Ascending. For this instruction, a synonym for DB.
IA  Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
FD  Full Descending. For this instruction, a synonym for IA.
IB  Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
ED  Empty Descending. For this instruction, a synonym for IB.

See Standard assembler syntax fields on page F2-2516.

See Standard assembler syntax fields on page F2-2516.
<Rn> Is the general-purpose base register, encoded in the "Rn" field.

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers_with_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

Instructions with similar syntax but without the PC included in the registers list are described in LDM (User registers).

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;                        // UNDEFINED or NOP
    else
        length = 4*BitCount(registers) + 4;
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;

        for i = 0 to 14
            if registers<i> == '1' then
                R[i] = MemA[address,4]; address = address + 4;
                new_pc_value = MemA[address,4];

            if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
            if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

            AArch32.ExceptionReturn(new_pc_value, SPSR[]);
F7.1.65    LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC.

The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Assembler symbols

<><> See Standard assembler syntax fields on page F2-2516.
<#> See Standard assembler syntax fields on page F2-2516.
<%> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field.
For encoding T3: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

<%> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The SP can be used. For PC use see LDR (literal).
For encoding T1: is the general-purpose base register, encoded in the "Rn" field.
For encoding T3 and T4: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDR (literal).

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1
+ Specifies the offset is added to the base register.
For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.

For the post-indexed or pre-indexed variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For encoding T1 or T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the same 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.

For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T4: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDR (literal) on page J1-5384.

Assembler symbols

- <c> See Standard assembler syntax fields on page F2-2516.
- <q> See Standard assembler syntax fields on page F2-2516.
- <Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.
  For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- <label> For encoding A1 and T2: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.
  For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  - when U = 1
- <imm> For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
  For encoding T2: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  base = Align(PC, 4);
  address = if add then (base + imm32) else (base - imm32);
  data = MemU[address, 4];
  if t == 15 then
    if address<1:0> == '00' then
      LoadWritePC(data);
    else
      UNPREDICTABLE;
  else
    R[t] = data;
F7.1.71  LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see Memory accesses on page F2-2523.

The T32 form of LDR (register) does not support register writeback.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDR (register, A32) on page J1-5378.

Assembler symbols

`<c>`

See Standard assembler syntax fields on page F2-2516.

`<p>`

See Standard assembler syntax fields on page F2-2516.

`<Rt>`

For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For the offset or post-indexed variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field. For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

`<Rn>`

For encoding A1, T1 or T2: is the general-purpose base register, encoded in the "Rn" field. For the offset or post-indexed variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be used.

`+/-`

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

\[
\begin{align*}
- & \quad \text{when } U = 0 \\
+ & \quad \text{when } U = 1
\end{align*}
\]

`<Rm>`

Is the general-purpose index register, encoded in the "Rm" field.

`<shift>`

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F2-2520.
<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Assembler symbols

See Standard assembler syntax fields on page F2-2516.

<

See Standard assembler syntax fields on page F2-2516.

<Rt>

Is the general-purpose register to be transferred, encoded in the "Rt" field.
For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The SP can be used. For PC use see LDRB (literal).

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

For encoding T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRB (literal).

+/−

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

+ Specifies the offset is added to the base register.

<imm>

For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.

For the post-indexed or pre-indexed variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the same 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

**Operation for all encodings**

```plaintext
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);

Assembler symbols

<c>  See Standard assembler syntax fields on page F2-2516.
<q>  See Standard assembler syntax fields on page F2-2516.
<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC
can be used, but this is deprecated.
   For encoding A1, T1, T2: is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn> For encoding A1, T1 or T2: is the general-purpose base register, encoded in the "Rn" field.
   For the offset or post-indexed variant: is the general-purpose base register, encoded in the "Rn"
   field. The PC can be used.
+/−  Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted
   and encoded in the "U" field. It can have the following values:
   - when U = 0
   + when U = 1
+    Specifies the index register is added to the base register.
<Rm> Is the general-purpose index register, encoded in the "Rm" field.
<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts
   applied to a register on page F2-2520.
<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded
   in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
   offset_addr = if add then (R[n] + offset) else (R[n] - offset);
address = if index then offset_addr else R[n];
R[t] = ZeroExtend(MemU[address,1],32);
if wbback then R[n] = offset_addr;
F7.1.75  LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2523.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Assembler symbols

<

See Standard assembler syntax fields on page F2-2516.

>

See Standard assembler syntax fields on page F2-2516.

<

For encoding A1: is the first general-purpose register to be transferred, encoded in the “Rt” field. This register must be even-numbered and not R14.
For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<Rt2>\)

For encoding A1: is the second general-purpose register to be transferred. This register must be \(<R(t+1)>\).

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<\text{label}>\)

For encoding A1: the label of the literal data item that is to be loaded into \(<Rt>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into \(<Rt>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

\(\pm\)

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \(U = 0\)
- + when \(U = 1\)

\(<\text{imm}>\)

For encoding A1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.

**Operation for all encodings**

Decode for this encoding

if Rt == '1111' then SEE PLD (literal);

\[ t = \text{UInt}(Rt); \ imm32 = \text{ZeroExtend}(\text{imm12}, 32); \ add = (U == '1'); \]

// ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRH (literal) on page J1-5385.

Assembler symbols

- `<c>`  See Standard assembler syntax fields on page F2-2516.
- `<q>`  See Standard assembler syntax fields on page F2-2516.
- `<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.
<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<imm> For encoding A1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = ZeroExtend(data, 32);
F7.1.85   LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F2-2523.

A1

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRH (register) on page J1-5380.

Assembler symbols

- \(<c>\) See Standard assembler syntax fields on page F2-2516.
- \(<q>\) See Standard assembler syntax fields on page F2-2516.
- \(<Rt>\) Is the general-purpose register to be transferred, encoded in the "Rt" field.
- \(<Rn>\) For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used.
  For the offset, post-indexed, pre-indexed or register-offset variant: is the general-purpose base register, encoded in the "Rn" field.
- \(+/-\) Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  + when U = 1

Selects the index register is added to the base register.
- \(<Rm>\) Is the general-purpose index register, encoded in the "Rm" field.
- \(<imm>\) If present, the size of the left shift to apply to the value from \(<Rm>\), in the range 1-3. \(<imm>\) is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if index then offset_addr else R[n];
  data = MemU[address,2];
  if wback then R[n] = offset_addr;
  R[t] = ZeroExtend(data, 32);
F7.1.86   LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2523.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

  R[t] = SignExtend(MemU[address,1], 32);
  if wback then R[n] = offset_addr;

---
F7.1.90   LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2523.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Assembler symbols

- **<c>:** See Standard assembler syntax fields on page F2-2516.
- **<p>:** See Standard assembler syntax fields on page F2-2516.
- **<Rt>:** Is the general-purpose register to be transferred, encoded in the "Rt" field.
<label>
For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/-
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

<imm>
For encoding A1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.

  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  data = MemU_unpriv[address,2];
  if postindex then R[n] = offset_addr;
  R[t] = SignExtend(data, 32);
F7.1.95   LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2523.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Assembler symbols

<c> See Standard assembler syntax fields on page F2-2516.

<q> See Standard assembler syntax fields on page F2-2516.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The SP can be used.
For encoding A2 and T1: is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1
For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<Rm> Is the general-purpose index register, encoded in the "Rn" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F2-2520.

+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE; // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,4];
    if postindex then R[n] = offset_addr;
    R[t] = data;
### F7.1.96 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

#### A1

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F2-2516.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<Rdm>` Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the first general-purpose source register, encoded in the "Rm" field.
- `<Rs>` Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F7.1.98   LSLS (immediate)

Logical Shift Left, setting flags (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

| 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 0 | imm3 | Rd | imm2 | 0 | 1 | Rm |

**MOV, shift or rotate by value variant**

\[
\text{LSR} (<c> \cdot W \{<Rd>,\} <Rm>, #<imm> // Inside IT block, and <Rd>, <Rm>, <imm> can be represented in T2
\]

is equivalent to

\[
\text{MOV} (<c>)\{<q>\} <Rd>, <Rm>, \text{LSR} #<imm>
\]

and is always the preferred disassembly.

\[
\text{LSR} (<c>)\{<q>\} \{<Rd>,\} <Rm>, #<imm>
\]
is equivalent to

\texttt{MOV\{<c>\}{<q>} <Rd>, <Rm>, LSR \#<imm>}

and is always the preferred disassembly.

**Assembler symbols**

- **<c>** See *Standard assembler syntax fields* on page F2-2516.
- **<q>** See *Standard assembler syntax fields* on page F2-2516.
- **<Rd>** For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2386. For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.
- **<Rm>** For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used. For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.
- **<imm>** For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as \(<\text{imm}>\) modulo 32. For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as \(<\text{imm}>\) modulo 32.

**Operation for all encodings**

The description of MOV, MOVs (register) gives the operational pseudocode for this instruction.
F7.1.101   LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

```

- `<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>` Is the first general-purpose source register, encoded in the "Rm" field.
- `<Rs>` Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F7.1.102   LSRS (immediate)

Logical Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for \(<Rd>\) identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_\(<current\_mode>\).
- The PE checks SPSR_\(<current\_mode>\) for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

MOVS, shift or rotate by value variant

LSRS.W {<Rd>,} <Rm>, #<imm> // Outside IT block, and <Rd>, <Rm>, <imm> can be represented in T2

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>

and is always the preferred disassembly.

LSRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>

and is always the preferred disassembly.

Assembler symbols

<c> See Standard assembler syntax fields on page F2-2516.

<q> See Standard assembler syntax fields on page F2-2516.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM
deprecates using the PC as the destination register, but if the PC is used, the instruction performs an
exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be
used.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

<imm> For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as
<imm> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as
<imm> modulo 32.

Operation for all encodings

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
F7.1.103 LSRS (register)

Logical Shift Right, setting flags (register) shifts a register value right by an immediate number of bits, shifting in zeros, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- `<Rs>`  Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

### Operation for all encodings

The description of \texttt{MOV, MOVS (register-shifted register)} gives the operational pseudocode for this instruction.
F7.1.104 MCR, MCR2

Move to Coprocessor from general-purpose register passes the value of a general-purpose register to a conceptual coprocessor.

This is a generic coprocessor instruction. The coproc field identifies the target conceptual coprocessor. This must be one of CP10, CP11, CP14, or CP15, and for these CP values, this manual defines the opc1, opc2, CRn, and CRd field values that are valid MCR and MCR2 instructions. Other encodings are UNDEFINED. For more information see Conceptual coprocessor support on page E1-2422 and General behavior of System registers on page G4-4190.

In an implementation that includes EL2, MCR accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see EL2 configurable controls on page G1-3927.

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Advanced SIMD and floating-point: 64-bit transfers accessing the SIMD and floating-point register file on page F5-2617.

**Assembler symbols**

- `<c>`
  - For encoding A1, T1 and T2: see Standard assembler syntax fields on page F2-2516.
  - For encoding A2: see Standard assembler syntax fields on page F2-2516. `<c>` must be AL or omitted.
  - See Standard assembler syntax fields on page F2-2516.
- `<coproc>`
  - Is the name of the coprocessor, encoded in the "coproc" field. The valid coprocessor names are p10, p11, p14, and p15.
- `<opc1>`
  - Is a coprocessor-specific opcode in the range 0 to 15, encoded in the "opc1" field.
- `<Rt>`
  - Is the first general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rt2>`
  - Is the second general-purpose register to be transferred, encoded in the "Rt2" field.
- `<CRm>`
  - Is a coprocessor register, encoded in the "CRm" field.

The relative significance of `<Rt2>` and `<Rt>` is IMPLEMENTATION DEFINED for IMPLEMENTATION DEFINED uses of the MCRR and MRRC instructions. For the architected uses, as described in this manual, `<Rt2>` transfers bits[63:32] of the selected coprocessor register, while `<Rt>` transfers bits[31:0].
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    Coproc_CheckInstr(cp, ThisInstr());
    Coproc_SendTwoWords(R[t2], R[t], cp, ThisInstr());
F7.1.106 MLA, MLAS

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of
the result are written to the destination register. These 32 bits do not depend on whether the source register values
are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely
affects performance on many implementations.

\]
\[
\text{if } d == 15 || n == 15 || m == 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13}
\]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- <c> See Standard assembler syntax fields on page F2-2516.
- <q> See Standard assembler syntax fields on page F2-2516.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
<Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Ra> Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
    addend = SInt(R[a]);   // addend = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
### F7.1.107 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

#### A1 variant

**MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>**

*Decode for this encoding*

\[
d = \text{UInt}(\text{Rd}); \ n = \text{UInt}(\text{Rn}); \ m = \text{UInt}(\text{Rm}); \ a = \text{UInt}(\text{Ra});
\]

if \( d = 15 \) \( n = 15 \) \( m = 15 \) \( a = 15 \) then UNPREDICTABLE;

#### T1 variant

**MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>**

*Decode for this encoding*

\[
d = \text{UInt}(\text{Rd}); \ n = \text{UInt}(\text{Rn}); \ m = \text{UInt}(\text{Rm}); \ a = \text{UInt}(\text{Ra});
\]

if \( d = 15 \) \( n = 15 \) \( m = 15 \) \( a = 15 \) then UNPREDICTABLE;

// ARMv8-A removes UNPREDICTABLE for R13

#### Notes for all encodings

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

#### Assembler symbols

- **<c>** See Standard assembler syntax fields on page F2-2516.
- **<q>** See Standard assembler syntax fields on page F2-2516.
- **<Rd>** Is the general-purpose destination register, encoded in the "Rd" field.
- **<Rn>** Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- **<Rm>** Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- **<Ra>** Is the third general-purpose source register holding the minuend, encoded in the "Ra" field.
Operation for all encodings

if ConditionPassed() then

    EncodingSpecificOperations();
    operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
    addend  = SInt(R[a]);  // addend  = UInt(R[a]) produces the same final results
    result = addend - operand1 * operand2;
    R[d] = result<31:0>;
F7.1.108   MOV, MOVS (immediate)

Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2386.
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

\[

if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```
Notes for all encodings

For information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<\> See Standard assembler syntax fields on page F2-2516.

<\> See Standard assembler syntax fields on page F2-2516.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used:
   ▪ For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
   ▪ For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding A2, T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<imm8> Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<imm16> For encoding A2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T3: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

For encoding T2: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then          // Can only occur for encoding A1
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
F7.1.109 MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases ASRS (immediate), ASR (immediate), LSLS (immediate), LSL (immediate), LSR (immediate), LSRS (immediate), RRXS, and RRX. See the Alias conditions on page F7-2878 table for details of when each alias is preferred.

### Assembler symbols

- **<c>**
  See Standard assembler syntax fields on page F2-2516.

- **<q>**
  See Standard assembler syntax fields on page F2-2516.

- **<Rd>**
  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:
  - For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of the instruction if <Rn> is not the LR, or if the optional shift or RRX argument is specified.

  For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:
  - The instruction causes a branch to the address moved to the PC. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - The instruction must either be outside an IT block or the last instruction of an IT block.

  For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

- **<Rm>**
  For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used.

  For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

- **<shift>**
  For encoding A1 and T3: is the type of shift to be applied to the source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11

  For encoding T2: is the type of shift to be applied to the source register, encoded in the "op" field. It can have the following values:
  - LSL when op = 00
  - LSR when op = 01
  - ASR when op = 10

- **<amount>**
  Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

### Operation for all encodings

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = shifted;
```

        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
F7.1.110 MOV, MOVS (register-shifted register)

Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases ASRS (register), ASR (register), LSLS (register), LSL (register), LSRS (register), LSR (register), RORS (register), and ROR (register). See the Alias conditions on page F7-2883 table for details of when each alias is preferred.

Assembler symbols

<\> See Standard assembler syntax fields on page F2-2516.

<\p> See Standard assembler syntax fields on page F2-2516.

<\Rdm> Is the general-purpose source register and the destination register, encoded in the "Rdm" field.

<\Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<\Rm> Is the general-purpose source register, encoded in the "Rm" field.
<type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (result, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```
F7.1.111  MOVT

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

<Rd>

Is the general-purpose destination register, encoded in the "Rd" field.

<imm16>

For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
F7.1.112  MRC, MRC2

Move to general-purpose register from Coprocessor causes a conceptual coprocessor to transfer a value to a
general-purpose register or to the condition flags.

This is a generic coprocessor instruction. The coproc field identifies the target conceptual coprocessor. This must be
one of CP10, CP11, CP14, or CP15, and for these CP values, this manual defines the opc1, opc2, CRn, and CRd field
values that are valid MRC and MRC2 instructions. Other encodings are UNDEFINED. For more information see
Conceptual coprocessor support on page E1-2422 and General behavior of System registers on page G4-4190.

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode,
meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be
permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see EL2
configurable controls on page G1-3927.

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

   EncodingSpecificOperations();
   Coproc_CheckInstr(cp, ThisInstr());
   \( (R[t2], R[t]) = \texttt{Coproc\_GetTwoWords}(cp, ThisInstr()); \)
\end{verbatim}
F7.1.114 MRS

Move Special register to general-purpose register moves the value of the APSR, CPSR, or SPSR_<current_mode> into a general-purpose register.

ARM recommends the APSR form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register, APSR on page E1-2390.

An MRS that accesses the SPSR is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the CPSR returns an UNKNOWN value for the CPSR. {E, A, I, F, M} fields.

    if PSTATE.EL == EL0 then
        // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
        // and for the M field, bits<4:0>
        psr_val<9:6> = bits(4) UNKNOWN;
        psr_val<4:0> = bits(5) UNKNOWN;
        R[d] = psr_val;
MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or SPSR of the specified mode, or the value of ELR_hyp on page G1-3831, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see Usage restrictions on the Banked register transfer instructions on page F7-3267.

F7.1.117 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the APSR, CPSR, or SPSR_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of MSR is normally only useful at the Application level for writing to APSR_nzcvq (CPSR_f).

If an MSR (immediate) moves selected bits of an immediate value to the CPSR, the PE checks whether the value being written to PSTATE.M is legal. See Illegal changes to PSTATE.M on page G1-3838.

An MSR (immediate) executed in User mode:

• Is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.
• Otherwise, does not update any CPSR field that is accessible only at EL1 or higher.

An MSR (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.

The CPSR.E bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value.

**A1**

\[
\begin{array}{ccccccccccccc}
| & | & | & | & | & | & | & | & | & |
\end{array}
\]

**A1 variant**

Applies when !(R == 0 && mask == 0000).

if mask == '0000' && R == '0' then SEE "Related encodings";
imm32 = A32ExpandImm(imm12); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly MSR (immediate) on page J1-5420.

Related encodings: MSR (immediate), and hints on page F4-2575.

**Assembler symbols**

- **<c>** See Standard assembler syntax fields on page F2-2516.
- **<q>** See Standard assembler syntax fields on page F2-2516.
- **<spec_reg>** Is one of:
  - APSR<bits>.
  - CPSR<fields>.
  - SPSR<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

- **c** mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
- **x** mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
- **s** mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvq, g, or nzcvqg. These map to the following CPSR_<fields> values:

- APSR_nzcvq is the same as CPSR_f (mask == '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

ARM recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register, APSR on page E1-2390.

<imm> Is an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

**Operation**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User, M32_System} then
            UNPREDICTABLE;
        else
            SPSRWriteByInstr(imm32, mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
        CPSRWriteByInstr(imm32, mask);
```
F7.1.118  MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the APSR, CPSR or SPSR_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the MSR instruction is being used at Application level and its destination is not APSR_nzcvq (CPSR_f).

If an MSR (register) moves selected bits of an immediate value to the CPSR, the PE checks whether the value being written to PSTATE.M is legal. See Illegal changes to PSTATE.M on page G1-3836.

An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the SPSR.

The CPSR.E bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value.

if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly MSR (register) on page J1-5391.
Assembler symbols

<c>   See Standard assembler syntax fields on page F2-2516.

<q>   See Standard assembler syntax fields on page F2-2516.

<spec_reg> Is one of:
   •  APSR_<bits>.
   •  CPSR_<fields>.
   •  SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:
   c  mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
   x  mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
   s  mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
   f  mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvq, g, or nzcvqg. These map to the following CPSR_<fields> values:
   •  APSR_nzcvq is the same as CPSR_f (mask== '1000').
   •  APSR_g is the same as CPSR_s (mask == '0100').
   •  APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

ARM recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register, APSR on page E1-2390.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   if write_spsr then
      if PSTATE.M IN {M32_User,M32_System} then
         UNPREDICTABLE;
      else
         SPSRWriteByInstr(R[n], mask);
   else
      // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
      CPSRWriteByInstr(R[n], mask);
**F7.1.119 MUL, MULS**

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<Rdm>\) Is the second general-purpose source register holding the multiplier and the destination register, encoded in the "Rdm" field.

\(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\) Is the first general-purpose destination register holding the multiplicand, encoded in the "Rn" field.

\(<Rm>\) Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field. If omitted, \(<Rd>\) is used.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    result = operand1 * operand2;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged

F7.1.120  MVN, MVNS (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for `<Rd>` identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

\{c\}  See Standard assembler syntax fields on page F2-2516.
\{q\}  See Standard assembler syntax fields on page F2-2516.
<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used:
   - For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
   - For the MVNS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

**Operation for all encodings**

```c
if ConditionPassed() then
   EncodingSpecificOperations();
   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
   result = NOT(shifted);
   if d == 15 then          // Can only occur for A32 encoding
      if setflags then
         ALUExceptionReturn(result);
      else
         ALUWritePC(result);
   else
      R[d] = result;
      if setflags then
         PSTATE.N = result<31>;
         PSTATE.Z = IsZeroBit(result);
         PSTATE.C = carry;
      // PSTATE.V unchanged
```

```
F7.1.122  **MVN, MVNS (register-shifted register)**

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

No Operation does nothing. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

A1

NOP{<c>}{<q>}

Decode for this encoding

// No additional decoding required

\[
\text{ORNS}\{<c>\}{<q>} {<Rd>,} <Rn>, <Rm> \{, <\text{shift}> \#<\text{amount}>\}
\]

**Decode for all variants of this encoding**

if \( Rn == \text{'1111'} \) then see MVN (register);
\[ d = \text{UInt}(Rd); n = \text{UInt}(Rn); m = \text{UInt}(Rm); \text{setflags} = (S == '1'); \]
\[ (\text{shift}_t, \text{shift}_n) = \text{DecodeImmShift}(\text{type}, \text{imm3}::\text{imm2}); \]
\[ \text{if } d == 15 || m == 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13} \]

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- \(<c>\)  See Standard assembler syntax fields on page F2-2516.
- \(<q>\)  See Standard assembler syntax fields on page F2-2516.
- \(<Rd>\)  Is the general-purpose destination register, encoded in the "Rd" field.
- \(<Rn>\)  Is the first general-purpose source register, encoded in the "Rn" field.
- \(<Rm>\)  Is the second general-purpose source register, encoded in the "Rm" field.
<shift>  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have
the following values:
  LSL  when type = 00
  LSR  when type = 01
  ASR  when type = 10
  ROR  when type = 11

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> =
LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] OR NOT(shifted);
  R[d] = result;
  if setflags then
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
F7.1.126  ORR, ORRS (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_"<current_mode>".
  - The PE checks SPSR_"<current_mode>" for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

**Notes for all encodings**

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page F2-2516*.
- `<q>` See *Standard assembler syntax fields on page F2-2516*.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. ARM deprecates using the PC as the destination register, but if the PC is used:
  - For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For the ORRS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

  For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

- `<Rn>` For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used.
  For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

- `<const>` For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions on page F4-2569* for the range of values.
  For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions on page F3-2540* for the range of values.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();
  result = R[n] OR imm32;
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
      else
      ALUWritePC(result);
    else
      R[d] = result;
    if setflags then
      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged
```
### F7.1.127 ORR, ORRS (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for `<Rd>` identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386](#).
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-3861](#).
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\]

#### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1

Architectural Constraints on UNPREDICTABLE behaviors.

Related Encodings: Data-processing (shifted register) on page F3-2552
Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2516.
\(<q>\) See Standard assembler syntax fields on page F2-2516.
\(<Rdn>\) Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.
\(<Rd>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<Rn>\). ARM deprecates using the PC as the destination register, but if the PC is used:
  • For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  • For the ORRS variant, the instruction performs an exception return, that restores PSTATE from SPSR_\(<\text{current\_mode}>\).

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<Rn>\).

\(<Rn>\) For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

\(<Rm>\) For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

\(<shift>\) Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Type Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>00</td>
</tr>
<tr>
<td>LSR</td>
<td>01</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>

\(<\text{amount}>\) Is the shift amount, in the range 1 to 31 (when \(<\text{shift}> = \text{LSL or ROR}) or 1 to 32 (when \(<\text{shift}> = \text{LSR or ASR}) encoded in the "imm5" field as \(<\text{amount}>\) modulo 32.

In T32 assembly:

- Outside an IT block, if \(\text{ORRS} \ <Rd>, \ <Rn>, \ <Rd>\) is written with \(<Rd>\) and \(<Rn>\) both in the range R0-R7, it is assembled using encoding T1 as though \(\text{ORRS} \ <Rd>, \ <Rn>\) had been written.
- Inside an IT block, if \(\text{ORR}<c> \ <Rd>, \ <Rn>, \ <Rd>\) is written with \(<Rd>\) and \(<Rn>\) both in the range R0-R7, it is assembled using encoding T1 as though \(\text{ORR}<c> \ <Rd>, \ <Rn>\) had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

```pseudo
if ConditionPassed() then
  EncodingSpecificOperations();
  (shifted, carry) = Shift_CR[R[m], shift_t, shift_n, PSTATE.C];
  result = R[n] OR shifted;
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
  if setflags then
```
PSTATE.N = result<31>;
PSTATE.Z = IsZeroBit(result);
PSTATE.C = carry;
// PSTATE.V unchanged
F7.1.128 **ORR, ORRS (register-shifted register)**

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

\[ \text{if } d == 15 || n == 15 || m == 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13} \]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<c>
See Standard assembler syntax fields on page F2-2516.

<q>
See Standard assembler syntax fields on page F2-2516.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<Rn>
Is the first general-purpose source register, encoded in the "Rn" field.

<Rm>
Is the second general-purpose source register, encoded in the "Rm" field.

<imm>
For encoding A1: the shift to apply to the value read from <Rm>, encoded in imm5. Is one of:

- omitted: No shift, encoded as 0b00000.
- 1-31: Left shift by specified number of bits, encoded as a binary number.

For encoding A1: the shift to apply to the value read from <Rm>, encoded in imm5. Is one of:

- omitted: Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>,<Rm>,<Rn> had been written.
- 1-32: Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

--- Note ---
An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

---

For encoding T1: the shift to apply to the value read from <Rm>, encoded in imm3:imm2. For PKHBT, it is one of:

- omitted: No shift, encoded as 0b00000.
- 1-31: Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

- omitted: Instruction is a pseudo-instruction and is assembled as though PKHTB{<c>}{<q>} <Rd>,<Rm>,<Rn> had been written.
- 1-32: Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

--- Note ---
An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

---

Operation for all encodings

<label>
The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.
+/-. Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.
For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.

Operation for all encodings

if ConditionPassed() then

Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F2-2516. <c> must be AL or omitted.
For encoding T1: see Standard assembler syntax fields on page F2-2516.

<q> See Standard assembler syntax fields on page F2-2516.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used.
For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

+/− Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted
and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

+ Specifies the index register is added to the base register.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the index register, encoded in the "type" field. It can have the
following values:
LSL when type = 00
LSR when type = 01
ASR when type = 10
ROR when type = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32
(when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2"
field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);

PLI{<c>}{<q>} <label>// Preferred syntax

PLI{<c>}{<q>} [PC, #<+-><imm>]/// Alternative syntax

**Decode for this encoding**

\[ n = 15; \ imm32 = \text{ZeroExtend}(\text{imm12}, 32); \ \text{add} = (U == '1'); \]

**Notes for all encodings**

For information about the CONstrained UNPredictable behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- **<>** For encoding A1: see Standard assembler syntax fields on page F2-2516. Must be AL or omitted. For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2516.

- **<q>** See Standard assembler syntax fields on page F2-2516.

- **<label>** The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

- **<Rn>** Is the general-purpose base register, encoded in the "Rn" field.

- **+-** Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - - when U = 0
  - + when U = 1

- **<imm>** For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

  For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

  For encoding T2: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

  For encoding T3: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as 0b1111 in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2479.
Operation for all encodings

</tbody>
</table>

T1 variant

PLI{<c>}{<q>} [Rn, {+}<Rm} , {LSL #<amount>}

Decode for this encoding

if Rn == '1111' then SEE PLI (immediate, literal);
 n = UInt(Rn);  m = UInt(Rm);  add = (U == '1');
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<>

For encoding A1: see Standard assembler syntax fields on page F2-2516. <*> must be AL or omitted.
For encoding T1: see *Standard assembler syntax fields on page F2-2516.*

<q>
See *Standard assembler syntax fields on page F2-2516.*

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/− Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted
and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

+ Specifies the index register is added to the base register.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the index register, encoded in the "type" field. It can have the
following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Type Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>0</td>
</tr>
<tr>
<td>LSR</td>
<td>1</td>
</tr>
<tr>
<td>ASR</td>
<td>10</td>
</tr>
<tr>
<td>ROR</td>
<td>11</td>
</tr>
</tbody>
</table>

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32
(when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2"
field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    Hint_PreloadInstr(address);
```
F7.1.135 POP

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

POP{<c>}{<q>} <registers>

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(register_list) > 1.

**Assembler symbols**

- `<>`  See Standard assembler syntax fields on page F2-2516.
- `<q>`  See Standard assembler syntax fields on page F2-2516.
- `<registers>` For encoding A1: is a list of two or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524. If the SP is in the list, the value of the SP after such an instruction is UNKNOWN. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386. ARM deprecates the use of this instruction with both the LR and the PC in the list.

For encoding T2: is a list of two or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of
lists of general-purpose registers and the PC on page F2-2524. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

**Operation for all encodings**

The description of LDM, LDMIA, LDMFD gives the operational pseudocode for this instruction.
F7.1.137 POP (single register)

Pop Single Register from Stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point just above the loaded data.

This instruction is an alias of the LDR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of LDR (immediate).
- The description of LDR (immediate) gives the operational pseudocode for this instruction.

**A1**

```
<table>
<thead>
<tr>

```

**Post-indexed variant**

`POP{<c>}{<q>} <single_register_list>`

is equivalent to

`LDR{<c>}{<q>} <Rt>, [SP], #4`

and is always the preferred disassembly.

**Assembler symbols**

- `<>` See *Standard assembler syntax fields* on page F2-2516.
- `<q>` See *Standard assembler syntax fields* on page F2-2516.
- `<single_register_list>` Is the general-purpose register `<Rt>` to be loaded surrounded by `{` and `}`.
- `<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386*.
For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

Operation for all encodings

The description of LDR (immediate) gives the operational pseudocode for this instruction.
F7.1.138  PUSH

Push Multiple Registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

F7.1.155 RFE, RFEDA, RFEDB, RFEIA, RFEIB

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore PSTATE. This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

\[ \text{MOV}\langle\text{c}\rangle\langle\text{q}\rangle\langle\text{Rd}\rangle,\langle\text{RN}\rangle,\text{ROR}\langle\text{Rs}\rangle \]

and is always the preferred disassembly.

**Assembler symbols**

- \(\langle\text{c}\rangle\) See *Standard assembler syntax fields* on page F2-2516.
- \(\langle\text{q}\rangle\) See *Standard assembler syntax fields* on page F2-2516.
- \(\langle\text{Rdm}\rangle\) Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
- \(\langle\text{Rd}\rangle\) Is the general-purpose destination register, encoded in the "Rd" field.
- \(\langle\text{Rn}\rangle\) Is the first general-purpose source register, encoded in the "Rn" field.
- \(\langle\text{Rm}\rangle\) Is the first general-purpose source register, encoded in the "Rm" field.
- \(\langle\text{Rs}\rangle\) Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
### F7.1.158 RORS (immediate)

Rotate Right, setting flags (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for `<Rd>` identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

#### Assembler symbols

<c>

See Standard assembler syntax fields on page F2-2516.
See *Standard assembler syntax fields* on page F2-2516.

**<Rd>**
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

**<Rm>**
For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used.
For encoding T3: is the general-purpose source register, encoded in the "Rm" field.

**<imm>**
For encoding A1: is the shift amount, in the range 1 to 31, encoded in the "imm5" field.
For encoding T3: is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

**Operation for all encodings**

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
RORS (register)

Rotate Right, setting flags (register) provides the value of the contents of a register rotated by a variable number of bits, and updates the condition flags based on the result. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

- \(<c>\) See *Standard assembler syntax fields* on page F2-2516.
- \(<q>\) See *Standard assembler syntax fields* on page F2-2516.
- \(<Rd>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2386.
  
  For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

- \(<Rm>\) For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used.
  
  For encoding T3: is the general-purpose source register, encoded in the "Rm" field.
Operation for all encodings

The description of MOV, MOV (register) gives the operational pseudocode for this instruction.
**F7.1.161   RRXS**

Rotate Right with Extend, setting flags provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

If the destination register is not the PC, this instruction updates the condition flags based on the result, and bit[0] is shifted into the Carry flag.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3861.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

**A1**

if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
  R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

F7.1.165   RSC, RSCS (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

| RSC variant |
| Applications when S = 0. |
| RSC{<c>}{<q>} {<Rd>,} <Rn>, #<const> |

| RSCS variant |
| Applications when S = 1. |
| RSCS{<c>}{<q>} {<Rd>,} <Rn>, #<const> |

Decode for all variants of this encoding

\[ d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad \text{setflags} = (S == '1'); \quad \text{imm32} = \text{A32ExpandImm}(\text{imm12}); \]

Assembler symbols

- <c> See Standard assembler syntax fields on page F2-2516.
- <q> See Standard assembler syntax fields on page F2-2516.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:
  - For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
  - For the RSCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field. The PC can be used.

if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

- `<>`
  - See Standard assembler syntax fields on page F2-2516.
- `<q>`
  - See Standard assembler syntax fields on page F2-2516.
- `<Rdn>`
  - Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.
- `<Rd>`
  - For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. ARM deprecates using the PC as the destination register, but if the PC is used:
    - For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
    - For the SBCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
  - For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.
- `<Rn>`
  - For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used.
  - For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>`
  - For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.
  - For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>`
  - Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
    - LSL when type = 00
    - LSR when type = 01
    - ASR when type = 10
    - ROR when type = 11
- `<amount>`
  - Is the shift amount, in the range 1 to 31 (when `<shift>` = LSL or ROR) or 1 to 32 (when `<shift>` = LSR or ASR) encoded in the "imm5" field as `<amount>` modulo 32.

Operation for all encodings

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F7.1.173 SBC, SBCS (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

Flag setting variant
Applies when \( S = 1 \).

\[
\text{SBCS}\{c\}\{q\} \{<Rd>,\} <Rn>, <Rm>, \text{type} <Rs>
\]

Not flag setting variant
Applies when \( S = 0 \).

\[
\text{SBC}\{c\}\{q\} \{<Rd>,\} <Rn>, <Rm>, \text{type} <Rs>
\]

Decode for all variants of this encoding
\[
d = \text{UInt}(Rd); \quad n = \text{ UInt}(Rn); \quad m = \text{ UInt}(Rm); \quad s = \text{ UInt}(Rs);
\text{ setflags} = (S == '1'); \quad \text{shift}_t = \text{DecodeRegShift(type)};
\text{if } d == 15 || n == 15 || m == 15 || s == 15 \text{ then UNPREDICTABLE;}
\]

Notes for all encodings
For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

\(c\)
See Standard assembler syntax fields on page F2-2516.

\(q\)
See Standard assembler syntax fields on page F2-2516.

\(Rd\)
Is the general-purpose destination register, encoded in the "Rd" field.

\(Rn\)
Is the first general-purpose source register, encoded in the "Rn" field.

\(Rm\)
Is the second general-purpose source register, encoded in the "Rm" field.

\(type\)
Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- \(\text{LSL}\) when \(\text{type} = 00\)
- \(\text{LSR}\) when \(\text{type} = 01\)
- \(\text{ASR}\) when \(\text{type} = 10\)
- \(\text{ROR}\) when \(\text{type} = 11\)

\(Rs\)
Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
  R[d] = result;
  if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
F7.1.174   SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

A1

Assembler symbols

- **<c>**
  See Standard assembler syntax fields on page F2-2516.

- **<q>**
  See Standard assembler syntax fields on page F2-2516.

- **<Rd>**
  Is the general-purpose destination register, encoded in the "Rd" field.

- **<Rn>**
  Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.

- **<Rm>**
  Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Overflow

If the signed integer division \(0x80000000 \div 0xFFFFFFFF\) is performed, the pseudocode produces the intermediate integer result \(+2^{31}\), that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to \(<Rd>\) must be the bottom 32 bits of the binary representation of \(+2^{31}\). So the result of the division is \(0x80000000\).
Operation for all encodings

if `ConditionPassed()` then
    EncodingSpecificOperations();
    if `SInt(R[m])` == 0 then
        if `IntegerZeroDivideTrappingEnabled()` then

### F7.1.186 SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information see Secure Monitor Call (SMC) exception on page G1-3882.

SMC is available only for software executing at EL1 or higher. It is **UNDEFINED** in User mode.

If the values of HCR.TSC and SCR.SCD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception that is taken to EL3. When EL3 is using AArch32, this exception is taken to Monitor mode. When EL3 is using AArch64, it is the SCR_EL3.SMD bit, rather than the SCR.SCD bit, that can change the effect of executing an SMC instruction.

If the value of HCR.TSC is 1, execution of an SMC instruction in a Non-secure EL1 mode generates an exception that is taken to EL2, regardless of the value of SCR.SCD. When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information see Traps to Hyp mode of Non-secure PL1 execution of SMC instructions on page G1-3933.

If the value of HCR.TSC is 0 and the value of SCR.SCD is 1, the SMC instruction is:

- **UNDEFINED** in Non-secure state.
- **CONSTRAINED UNPREDICTABLE** if executed in Secure state at EL1 or higher.

#### A1

SMC{<c>}{<q>} {#}<imm4>

**Decode for this encoding**

// imm4 is for assembly/disassembly only and is ignored by hardware
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<c> See Standard assembler syntax fields on page F2-2516.

<q> See Standard assembler syntax fields on page F2-2516.

<imm4> Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the "imm4" field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but ARM does not recommend this.

Operation for all encodings

### F7.1.187  SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets `PSTATE.Q` to 1. It is not possible for overflow to occur during the multiplication.

F7.1.188 SMLAD, SMLDX

Signed Multiply Accumulate Dual performs two signed 16 x 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets PSTATE.Q to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications.

F7.1.192  SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets PSTATE.Q to 1. No overflow can occur during the multiplication.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 - product2 + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        PSTATE.Q = '1';
F7.1.194 SMLSLD, SMLSLDX

Signed Multiply Subtract Long Dual performs two signed 16 x 16-bit multiplications. It adds the difference of the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^64.

\]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly SMULL on page J1-5397.

Assembler symbols

\[
<>
\]

See Standard assembler syntax fields on page F2-2516.

\[
<q>
\]

See Standard assembler syntax fields on page F2-2516.
<RdLo> Is the general-purpose destination register for the lower 32 bits of the result, encoded in the "RdLo" field.

<RdHi> Is the general-purpose destination register for the upper 32 bits of the result, encoded in the "RdHi" field.

<Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```
SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

    // Signed overflow cannot occur
F7.1.202  SMUSD, SMUSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

F7.1.203  SRS, SRSDA, SRSDB, SRSIA, SRSIB

Store Return State stores the LR_<current_mode> and SPSR_<current_mode> to the stack of a specified mode. For information about memory accesses see Memory accesses on page F2-2523.

SRS is UNDEFINED in Hyp mode.

SRS is UNPREDICTABLE if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that Table G1-2 on page G1-3820 does not show.
- Not accessible from the context that the SRS instruction is executed in, as follows:
  - A mode that is at a higher Exception level.
  - When executing in Non-secure state, Monitor mode.

SRS is trapped to EL3 if all of the following are true:

- It is executed at Secure PL1.
- The specified mode is monitor mode.
- EL3 is using AArch64.

See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.

F7.1.209  STC, STC2

Store Coprocessor stores data from a conceptual coprocessor to a sequence of consecutive memory addresses.

This is a generic coprocessor instruction. The coproc field identifies the target conceptual coprocessor. This must be one of CP10, CP11, CP14, or CP15, and for these CP values, this manual defines the imm8, Crd, and D field values that are valid STC and STC2 instructions. Other encodings are UNDEFINED. For more information see Conceptual coprocessor support on page E1-2422 and General behavior of System registers on page G4-4190.

In an implementation that includes EL2, the permitted STC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general CP14 accesses to debug registers on page G1-3942.

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation for all encodings**

```
if ConditionPassed() then
  EncodingSpecificOperations();
  address = R[n];
  if AArch32.ExclusiveMonitorsPass(address, 4) then
    MemO[address, 4] = R[t];
    R[d] = ZeroExtend('0');
  else
    R[d] = ZeroExtend('1');
```
F7.1.213   STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page B2-90.

For more information about support for shared memory see Synchronization and semaphores on page E2-2466. For information about memory accesses see Memory accesses on page F2-2523.

### F7.1.217 STM, STMIA, STMEA

Store Multiple (Increment After, Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

For details of related system instructions see STM (User registers).

Assembler symbols

IA Is an optional suffix for the Increment After form.

<0> See Standard assembler syntax fields on page F2-2516.

<0> See Standard assembler syntax fields on page F2-2516.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

\]
F7.1.218 STM (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

\]

if n == 1S || BitCount(registers) < 1 then UNPREDICTABLE;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STM (User registers) on page J1-5422.

Assembler symbols

- `<amode>` is one of:
  - DA: Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
  - ED: Empty Descending. For this instruction, a synonym for DA.
  - DB: Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
  - FD: Full Descending. For this instruction, a synonym for DB.
  - IA: Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
  - EA: Empty Ascending. For this instruction, a synonym for IA.
  - IB: Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
  - FA: Full Ascending. For this instruction, a synonym for IB.

- `<c>` See Standard assembler syntax fields on page F2-2516.

- `<q>` See Standard assembler syntax fields on page F2-2516.

- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

- `<registers>` Is a list of one or more registers, separated by commas and surrounded by {} and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

                MemA[address,4] = PCStoreValue();
F7.1.219   STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2524.

For details of related system instructions see STM (User registers).

Assembler symbols

\(<c>\)  
See Standard assembler syntax fields on page F2-2516.

\(<q>\)  
See Standard assembler syntax fields on page F2-2516.

\(<Rn>\)  
Is the general-purpose base register, encoded in the "Rn" field.

\(!\)  
The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

\(<register>\)  
For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRB (immediate), T32 on page J1-5405 and STRB (immediate, A32) on page J1-5406.

Assembler symbols

<c> See Standard assembler syntax fields on page F2-2516.

<q> See Standard assembler syntax fields on page F2-2516.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The SP can be used. The PC can be used, but this is deprecated.

For the post-indexed or pre-indexed variant: is the general-purpose base register, encoded in the "Rn" field. The SP can be used.
For encoding T1, T2 or T3: is the general-purpose base register, encoded in the "Rn" field.

+/-
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when $U = 0$
+ when $U = 1$

+ Specifies the offset is added to the base register.

$<imm>$
For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.

For the post-indexed or pre-indexed variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the same 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

**Operation for all encodings**

if wbacc then R[n] = offset_addr;
F7.1.226   STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see Memory accesses on page F2-2523.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRD (register) on page J1-5413.

**Assembler symbols**

\(<c>\)  See Standard assembler syntax fields on page F2-2516.

\(<q>\)  See Standard assembler syntax fields on page F2-2516.

\(<Rt>\)  Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must
be even-numbered and not R14.

\(<Rt2>\)  Is the second general-purpose register to be transferred. This register must be \(<R(t+1)>\).

\(<Rn>\)  For the offset variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be
used, but this is deprecated.

For the post-indexed and pre-indexed variant: is the general-purpose base register, encoded in the
"Rn" field.
+/-  Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  + when U = 1

<Rm>  Is the general-purpose index register, encoded in the "Rm" field.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STREX on page J1-5414.

**Assembler symbols**

- \(<c>\) See Standard assembler syntax fields on page F2-2516.
- \(<q>\) See Standard assembler syntax fields on page F2-2516.
- \(<\text{Rd}>\) Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.
<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<imm> For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');

Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn>
For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding A1, T1, T2, T3: is the general-purpose base register, encoded in the "Rn" field.
+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when $U = 0$
+ when $U = 1$

+ specifies the offset is added to the base register.

<imm>

For encoding A1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm4H:imm4L" field.

For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.

For the post-indexed or pre-indexed variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the same 0 to 62 defaulting to 0 and encoded in the "imm5" field as $<imm>/2$.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```plaintext
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        MemU[address,2] = R[t]<15:0>;
        if wback then R[n] = offset_addr;
    else
        if ConditionPassed() then
            EncodingSpecificOperations();
            offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
            address = if index then offset_addr else R[n];
            MemU[address,2] = R[t]<15:0>;
            if wback then R[n] = offset_addr;
```

F7.1.234   STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F2-2523.

Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRT on page J1-5411.

Assembler symbols

See Standard assembler syntax fields on page F2-2516.
See Standard assembler syntax fields on page F2-2516.
For the offset variant: is the general-purpose register to be transferred, encoded in the "Rt" field.
For the post-indexed variant: is the general-purpose register to be transferred, encoded in the "Rt" field.
The PC can be used, but this is deprecated.
For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The SP can be
used.
For encoding A2 and T1: is the general-purpose base register, encoded in the "Rn" field.
For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to
+ if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1
For encoding A2: specifies the index register is added to or subtracted from the base register,
defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1
Is the general-purpose index register, encoded in the "Rm" field.
The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts
applied to a register on page F2-2520.
+ Specifies the offset is added to the base register.
For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095,
defaulting to 0 and encoded in the "imm12" field.
For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255,
defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

if ConditionPassed() then
  if PSTATE.EL == EL2 then UNPREDICTABLE; // Hyp mode
  EncodingSpecificOperations();
  offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  if t == 15 then // Only possible for encodings A1 and A2
data = PCStoreValue();
else
data = R[t];
MemU_unpriv[address,4] = data;
if postindex then R[n] = offset_addr;
F7.1.237   SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias.

This instruction is an alias of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The description of ADR gives the operational pseudocode for this instruction.

SUB{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is the preferred disassembly when i:imm3:imm8 = '000000000000'.

**Assembler symbols**

- `<>` See Standard assembler syntax fields on page F2-2516.
- `{}` See Standard assembler syntax fields on page F2-2516.
- `<Rd>` For encoding A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field.

- `<label>` For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into `Rd`. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset. If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset.
That is, the use of encoding A2 indicates that the required offset is minus the value of \texttt{imm32}.
Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions* on page F4-2569.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into \texttt{<Rd>}. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into \texttt{<Rd>}. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with \texttt{imm32} equal to the offset. If the offset is negative, encoding T2 is used, with \texttt{imm32} equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of \texttt{imm32}.
Permitted values of the size of the offset are 0-4095.

\texttt{<imm12>} Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

\texttt{<const>} An immediate value. See *Modified immediate constants in A32 instructions* on page F4-2569 for the range of values.

**Operation for all encodings**

The description of \texttt{ADR} gives the operational pseudocode for this instruction.
F7.1.238   SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see ERET.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

**Decode for this encoding**

if \( Rn == '1110' \) & IsZero\( (imm8) \) then SEE ERET;
d = 15; \( n = UInt(Rn) \); setflags = TRUE; imm32 = ZeroExtend\( (imm8, 32) \);
if \( n != 14 \) then UNPREDICTABLE;
if InITBlock() \&!LastInITBlock() then UNPREDICTABLE;

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly SUBS PC, LR and related instructions (A32) on page J1-5423 and SUBS PC, LR and related instructions (T32) on page J1-5423.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<p>\) See Standard assembler syntax fields on page F2-2516.

\(<Rdn>\) Is the general-purpose source and destination register, encoded in the "Rdn" field.

\(<imm8>\) For encoding T2: is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
For encoding T5: is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
If \( Rn \) is the LR and zero is used, see ERET.

\(<Rd>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<Rn>\). If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR.\(<\text{current\_mode}>\). ARM deprecates use of this instruction unless \(<Rn>\) is the LR.

For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<Rn>\).

\(<Rn>\) For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB, SUBS (SP minus immediate). If the PC is used, see ADR.
For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB, SUBS (SP minus immediate).

\(<imm3>\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

In the T32 instruction set, MOVSn{cc}{q} PC, LR is a pseudo-instruction for SUBSn{cc}{q} PC, LR, #0.

**Operation for all encodings**

```assembly
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F7.1.239   SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<
See Standard assembler syntax fields on page F2-2516.

>
See Standard assembler syntax fields on page F2-2516.

<Rd>
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see SUB, SUBS (SP minus register).

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB, SUBS (SP minus register).

<Rm>
For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift>
Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount>
Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;

F7.1.240  SUB, SUBS (register-shifted register)

Subtract (register-shifted register) subtracts a register-shifted register value from a register value, and writes
the result to the destination register. It can optionally update the condition flags based on the result.

A1

| [31] | 28|27|26|25|24|23|22|21|20|19 | 16|15 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

\end{align*}
\]

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1
Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<\text{c}>  See Standard assembler syntax fields on page F2-2516.
<\text{q}>  See Standard assembler syntax fields on page F2-2516.
<\text{Rd}>  Is the general-purpose destination register, encoded in the "Rd" field.
<\text{Rn}>  Is the first general-purpose source register, encoded in the "Rn" field.
<\text{Rm}>  Is the second general-purpose source register, encoded in the "Rm" field.
<\text{type}>  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have
the following values:
  \text{LSL}  when type = 00
  \text{LSR}  when type = 01
  \text{ASR}  when type = 10
  \text{ROR}  when type = 11
<\text{Rs}>  Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in
the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
F7.1.241  SUB, SUBS (SP minus immediate)

Subtract from SP (immediate) subtracts an immediate value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

• The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

• The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  — The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  — The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  — The instruction is UNDEFINED in Hyp mode.
  — The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<\text{imm7}>\) Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

\(<\text{Rd}>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. If the PC is used:

\(\cdot\) For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
• For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of this instruction unless <Rn> is the LR.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F4-2569 for the range of values.

For encoding T2: an immediate value. See Modified immediate constants in T32 instructions on page F3-2540 for the range of values.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F7.1.242 SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-3861.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

\(<\text{Rd}>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2386.

- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

\(<\text{Rm}>\) For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.
For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- **LSL** when type = 00
- **LSR** when type = 01
- **ASR** when type = 10
- **ROR** when type = 11

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F7.1.243 SVC

Supervisor Call causes a Supervisor Call exception. For more information, see Supervisor Call (SVC) exception on page G1-3879.

Note
SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

• If the SVC is executed in Hyp mode.

• If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3858

In these cases, the HSR identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see Use of the HSR on page G4-4177. The immediate field in the HSR:

• If the SVC is unconditional:
  — For the T32 instruction, is the zero-extended value of the imm8 field.
  — For the A32 instruction, is the least-significant 16 bits the imm24 field.

• If the SVC is conditional, is UNKNOWN.

Is the general-purpose source register, encoded in the "Rm" field.

<amount>
Is the rotate amount, encoded in the "rotate" field. It can have the following values:

(omitted) when rotate = 00
8 when rotate = 01
16 when rotate = 10
24 when rotate = 11
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0> = SignExtend(rotated<7:0>, 16);
    R[d]<31:16> = SignExtend(rotated<23:16>, 16);
F7.1.249  SXTH

Signed Extend Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

F7.1.250  TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

T1

<table>
<thead>
<tr>
<th>15 14 13 12</th>
<th>11 10 9 8</th>
<th>7 6 5 4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 0 1 1 0 1</td>
<td>Rn</td>
<td>1 1 1</td>
<td>1 0 0</td>
<td>0 0 0</td>
</tr>
</tbody>
</table>

**Byte variant**

Applies when \( H = 0 \).

\[ \text{TBB\{<c>\}{<q>} [<Rn>, <Rm>] // Outside or last in IT block} \]

**Halfword variant**

Applies when \( H = 1 \).

\[ \text{TBH\{<c>\}{<q>} [<Rn>, <Rm>, LSL #1] // Outside or last in IT block} \]

**Decode for all variants of this encoding**

\[
\begin{align*}
  n &= \text{UInt}(\text{Rn}); \\
  m &= \text{UInt}(\text{Rm}); \\
  \text{is\_tbh} &= (H == '1'); \\
  \text{if } m == 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13} \\
  \text{if } \text{In\_IT\_Block()} && !\text{Last\_In\_IT\_Block()} \text{ then UNPREDICTABLE;}
\end{align*}
\]

**Notes for all encodings**

For information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2516.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<Rn>` Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.
- `<Rm>` For the byte variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.
  
  For the halfword variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

**Operation**

\[
\begin{align*}
  \text{if } \text{ConditionPassed()} \text{ then} \\
  &\text{EncodingSpecificOperations();} \\
  \text{if is\_tbh then} \\
  &\text{halfwords} = \text{UInt}((\text{MemU}[\text{R}[n]+\text{LSL}(\text{R}[m], 1)], 2)); \\
  \text{else} \\

n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

#### Notes for all encodings

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

#### Assembler symbols

- `<q>`: See Standard assembler syntax fields on page F2-2516.
- `<Rn>`: Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>`: Is the second general-purpose source register, encoded in the "Rm" field.
- `<type>`: Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11
- `<Rs>`: Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

#### Operation

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```
F7.1.257  UADD16

Unsigned Add 16 performs two 16-bit unsigned integer additions, and writes the results to the destination register. It sets PSTATE.GE according to the results of the additions.

Assembler symbols

<>
See Standard assembler syntax fields on page F2-2516.

<q>
See Standard assembler syntax fields on page F2-2516.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<Rn>
Is the general-purpose source register, encoded in the "Rn" field.

<lsb>
For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width>
Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
F7.1.261 UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

A1

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 |   |   |   | 8 |7 |6 |5 |4 |3 |0] imm12
[1 1 1 0 0 1 1 1 1 1 1 1 1 1 1 | imm4]
```

A1 variant

UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

\[
imm32 = \text{ZeroExtend}(imm12:imm4, 32);
\]

// imm32 is for assembly and disassembly only, and is ignored by hardware.

T1

```
[15 14 13 12|11 10 9 | 8 |7 |   |   |   | 0] imm8
[1 1 0 1 1 1 1 0]
```

T1 variant

UDF{<c>}{<q}> {#}<imm>

Decode for this encoding

\[
imm32 = \text{ZeroExtend}(imm8, 32);
\]

// imm32 is for assembly and disassembly only, and is ignored by hardware.

T2

```
[15 14 13 12|11 10 9 | 8 |7 |6 |5 |4 |3 |0|15 14 13 12|11 |   |   | 0] imm12
[1 1 1 1 0 1 1 1 1 1 1 | imm4 | 1 0 | 1 0]
```

T2 variant

UDF{<c>}.W {#}<imm>// <imm> can be represented in T1

UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

\[
imm32 = \text{ZeroExtend}(imm4:imm12, 32);
\]

// imm32 is for assembly and disassembly only, and is ignored by hardware.
Assembler symbols

<
For encoding A1: see Standard assembler syntax fields on page F2-2516. < must be AL or omitted.
For encoding T1 and T2: see Standard assembler syntax fields on page F2-2516. ARM deprecates using any < value other than AL.
</
See Standard assembler syntax fields on page F2-2516.

<imm>
For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.
For encoding T1: is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.
For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   UNDEFINED;
F7.1.262   UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See Divide instructions on page F1-2489 for more information about this instruction.

Assembler symbols

<> See Standard assembler syntax fields on page F2-2516.

<> See Standard assembler syntax fields on page F2-2516.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<imm> Is the bit position for saturation, in the range 0 to 31, encoded in the "sat_imm" field.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

<amount> For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  operand = Shift(R[n], shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
  (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
  R[d] = ZeroExtend(result, 32);
  if sat then
    PSTATE.Q = '1';
### F7.1.281 USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.

This instruction sets $PSTATE.Q$ to 1 if the operation saturates.

#### A1

```

F7.2 Encoding and use of Banked register transfer instructions

Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- Register arguments in the Banked register transfer instructions.
- Usage restrictions on the Banked register transfer instructions on page F7-3267.
- Encoding the register argument in the Banked register transfer instructions on page F7-3268.
- Pseudocode support for the Banked register transfer instructions on page F7-3269.

For descriptions of the instructions see MRS (Banked register) on page F7-2894 and MSR (Banked register) on page F7-2897.

F7.2.1 Register arguments in the Banked register transfer instructions

Figure F7-1 shows the Banked general-purpose registers and Special-purpose registers:

![Banked registers diagram](image)

For the general-purpose registers, if no other register is shown, the current mode register is the _usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0_usr - R12_usr, SP_hyp, LR_usr, SPSR_hyp, ELR_hyp}.
- For Abort mode, is {R0_usr - R12_usr, SP_abt, LR_abt, SPSR_abt}.

Figure F7-1 Banking of general-purpose and Special-purpose registers

Figure F7-1 is based on Figure G1-2 on page G1-3823, that shows the complete set of general-purpose registers and Special-purpose registers accessible in each mode.

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some SPSRs, as described in Usage restrictions on the Banked register transfer instructions on page F7-3267.
- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.

Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in Figure F7-1, or an alternative name for SP or LR. These registers can be grouped as follows:

- R8-R12: Each of these registers has two Banked copies, _usr and _fiq, for example R8_usr and R8_fiq.
- SP: There is a Banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.
- LR: There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode.
SPSR  There is a Banked copy of SPSR for every mode except System mode and User mode.

ELR_hyp  Except for the operations provided by MR5 (Banked register) and MSR (Banked register), ELR_hyp is accessible only from Hyp mode. It is not Banked.

F7.2.2 Usage restrictions on the Banked register transfer instructions

MR5 (Banked register) and MSR (Banked register) instructions are UNPREDICTABLE if any of the following applies:

- The instruction is executed in User mode.
- The instruction accesses a Banked register that is not implemented, or that either:
  - Is not accessible from the current Privilege level and Security state.
  - Can be accessed from the current mode by using a different instruction.

An MR5 (Banked register) or an MSR (Banked register) executed:

- At Non-secure EL1 cannot access any Hyp mode Banked registers.
- At Non-secure EL1 or EL2 cannot access any Monitor mode Banked registers.
- In a Secure mode other than Monitor mode cannot access any Hyp Banked registers.

This means that the Banked registers that MR5 (Banked register) and MSR (Banked register) instructions cannot access are:

From Monitor mode

- The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

From Hyp mode

- The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

--- Note ---
MR5 (Banked register) and MSR (Banked register) instructions can access the current mode register ELR_hyp.

From FIQ mode

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

From System mode

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_usr-R12_usr, SP usr, and LR_usr.

From Supervisor mode, Abort mode, Undefined mode, and IRQ mode

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
- The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.

If EL3 is using AArch64, all MR5 (Banked register) and MSR (Banked register) accesses to the Monitor mode registers from Secure EL1 modes are trapped to EL3. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.

For more information, see:

- Encoding the register argument in the Banked register transfer instructions on page F7-3268.
- Pseudocode support for the Banked register transfer instructions on page F7-3269.
- MRS (Banked register) on page F7-2894.
• MSR (Banked register) on page F7-2897.

--- Note ---

UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

### F7.2.3 Encoding the register argument in the Banked register transfer instructions

The MRS (Banked register) and MSR (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the SPSR, and Table F7-1 shows how the SYSm field defines the required register argument.

<table>
<thead>
<tr>
<th>SYSm&lt;2:0&gt;</th>
<th>SYSm&lt;4:3&gt;</th>
<th>R8_usr</th>
<th>R9_usr</th>
<th>R10_usr</th>
<th>R11_usr</th>
<th>R12_usr</th>
<th>SP_usr</th>
<th>LR_usr</th>
<th>SP_irq</th>
<th>LR_irq</th>
<th>UNPREDICTABLE</th>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
F7.2.4 Pseudocode support for the Banked register transfer instructions

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRaccessValid()` check the validity of MRS (Banked register) and MSR (Banked register) accesses. That is, they filter the accesses that are UNPREDICTABLE either because:

- They attempt to access a register that Usage restrictions on the Banked register transfer instructions on page F7-3267 shows is not accessible.
- They use an SYS<4:0> encoding that Encoding the register argument in the Banked register transfer instructions on page F7-3268 shows as UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to ELR_hyp, and `SPSRaccessValid()` applies to accesses to the SPSRs.
F7 T32 and A32 Base Instruction Set Instruction Descriptions

F7.2 Encoding and use of Banked register transfer instructions
Chapter F8
T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• Alphabetical list of floating-point and Advanced SIMD instructions on page F8-3272.

Note

Some headings in this chapter use the term floating-point register. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.
F8.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see *Format of instruction descriptions* on page F2-2512.

This section is formatted so that each instruction description starts on a new page.
F8.1.1 AESD

AES single round decryption.

**A1**

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 12|11 10 9 8 | 7 6 5 4 | 3 0 |
| 1 1 1 1 0 0 1 1 | D 1 1 | size 0 0 | Vd 0 0 1 1 0 1 | M 0 | Vm |
```

**A1 variant**

AESD.<dt> <Qd>, <Qm>

*Decode for this encoding*

if size != '00' then UNDEFINED;
if Vd<0> == '1' || Vm<0> == '1' then UNDEFINED;
\[ d = \text{UInt}(O:Vd); m = \text{UInt}(M:Vm); \]

if size != '00' then UNDEFINED;
if Vd<0> == '1' || Vm<0> == '1' then UNDEFINED;
\[ d = \text{UInt}(O:Vd); m = \text{UInt}(M:Vm); \]
if InITBlock() then UNPREDICTABLE;

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 *Architectural Constraints on UNPREDICTABLE behaviors*.

**Assembler symbols**

*<dt>*  
Is the data type, encoded in the "size" field. It can have the following values:
- 8 when size = 00

It is reserved when:
- size = 01.
- size = 1x.

*<Qd>*  
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

*<Qm>*  
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    op1 = Q[d>>1]; op2 = Q[m>>1];
    Q[d>>1] = AESInvSubBytes(AESInvShiftRows(op1 EOR op2));
### F8.1.2 AESE

AES single round encryption.

```

T1 variant

AESMC.<dt> <Qd>, <Qm>

Decode for this encoding

if size != '00' then UNDEFINED;
if Vd<0> == '1' ||Vm<0> == '1' then UNDEFINED;
d = UInt(D:Vd); m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<dt> Is the data type, encoded in the "size" field. It can have the following values:
8 when size = '00
It is reserved when:
• size = '01.
• size = '1x.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    Q[d>>1] = AESMixColumns(Q[m>>1]);
F8.1.5 FLDMDBX

FLDMDBX loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register. ARM deprecates use of FLDMDBX, except for disassembly purposes, and reassembly of disassembled code.

This instruction is an alias of the VLDM, VLDMDB, VLMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VLDM, VLDMDB, VLMIA.
- The description of VLDM, VLDMDB, VLMIA gives the operational pseudocode for this instruction.

**A1**

Decrement Before variant

FLDMDBX{<c>}{<q>} <Rn>{!}, <dreglist>

is equivalent to

VLDMDB{<c>}{<q>} <Rn>{!}, <dreglist>

and is the preferred disassembly when imm8<0> == '1'.

**T1**

Decrement Before variant

FLDMDBX{<c>}{<q>} <Rn>{!}, <dreglist>

is equivalent to

VLDMDB{<c>}{<q>} <Rn>{!}, <dreglist>

and is the preferred disassembly when imm8<0> == '1'.

**Assembler symbols**

- `{<c>` See Standard assembler syntax fields on page F2-2516.
- `{<q>` See Standard assembler syntax fields on page F2-2516.
- `<Rn>` For encoding A1: is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

- '!` Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

- `<dreglist>` Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.
Operation for all encodings

The description of VLDM, VLDMDB, VLDMIA gives the operational pseudocode for this instruction.
F8.1.6   FLDMIAX

FLDMIAX loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register. ARM deprecates use of FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

This instruction is an alias of the VLDM, VLDMD, VLDMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VLDM, VLDMD, VLDMIA.
- The description of VLDM, VLDMD, VLDMIA gives the operational pseudocode for this instruction.

**A1**

\[
\begin{array}{cccccccccc}
\hline
1 & 1 & 1 & 0 & 0 & 1 & D & W & 1 & Rn & Vd & 1 & 0 & 1 & 1 & \text{imm8} \\
\end{array}
\]

**Increment After variant**

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

is equivalent to

VLDM{<c>}{<q>} <Rn>{!}, <dreglist>

and is the preferred disassembly when imm8<0> == '1'.

**T1**

\[
\begin{array}{cccccccccc}
15 & 14 & 13 & 12 & 11 & 10 & 9 & 8 & 7 & 6 & 5 & 4 & 3 & 0 & 15 & 12 & 11 & 10 & 9 & 8 & 7 & 0 \\
\hline
1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & D & W & 1 & Rn & Vd & 1 & 0 & 1 & 1 & \text{imm8} \\
\end{array}
\]

**Increment After variant**

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

is equivalent to

VLDM{<c>}{<q>} <Rn>{!}, <dreglist>

and is the preferred disassembly when imm8<0> == '1'.

**Assembler symbols**

- `<c>`  
  See Standard assembler syntax fields on page F2-2516.

- `<q>`  
  See Standard assembler syntax fields on page F2-2516.

- `<Rn>`  
  For encoding A1: is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
  
  For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

- `!`  
  Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

- `<dreglist>`  
  Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.
Operation for all encodings

The description of VLDM, VLMDB, VLDMIA gives the operational pseudocode for this instruction.
F8.1.7 FSTMDBX

FSTMDBX stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register. ARM deprecates use of FSTMDBX, except for disassembly purposes, and reassembly of disassembled code.

This instruction is an alias of the VSTM, VSTMDB, VSTMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VSTM, VSTMDB, VSTMIA.
- The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.

A1

Decrement Before variant

\[
\text{FSTMDBX}\{<c>\}{<q>} <Rn>{!}, <dreglist>
\]

is equivalent to

\[
\text{VSTMDB}{<c>}{<q>} <Rn>{!}, <dreglist>
\]

and is the preferred disassembly when \(\text{imm8}<0> == '1'\).

T1

Decrement Before variant

\[
\text{FSTMDBX}\{<c>\}{<q>} <Rn>{!}, <dreglist>
\]

is equivalent to

\[
\text{VSTMDB}{<c>\{<q}\} <Rn>{!}, <dreglist>
\]

and is the preferred disassembly when \(\text{imm8}<0> == '1'\).

Assembler symbols

- \(<c>\) See Standard assembler syntax fields on page F2-2516.
- \(<q>\) See Standard assembler syntax fields on page F2-2516.
- \(<Rn>\) For encoding A1: is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
  
  For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

- ! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

- \(<dreglist>\) Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.
Operation for all encodings

The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.
F8.1.8 **FSTMIAX**

FSTMIAX stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register. ARM deprecates use of FSTMIAX, except for disassembly purposes, and reassembly of disassembled code.

This instruction is an alias of the **VSTM, VSTMDB, VSTMIA** instruction. This means that:

- The encodings in this description are named to match the encodings of **VSTM, VSTMDB, VSTMIA**.
- The description of **VSTM, VSTMDB, VSTMIA** gives the operational pseudocode for this instruction.

**A1**

Increment After variant

FSTMIAX\{<c>\}{<q>} <Rn>{!}, <dreglist>

is equivalent to

VSTM\{<c>\}{<q>} <Rn>{!}, <dreglist>

and is the preferred disassembly when imm8<0> == '1'.

**T1**

Increment After variant

FSTMIAX\{<c>\}{<q>} <Rn>{!}, <dreglist>

is equivalent to

VSTM\{<c>\}{<q>} <Rn>{!}, <dreglist>

and is the preferred disassembly when imm8<0> == '1'.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F2-2516.

\(<q>\) See Standard assembler syntax fields on page F2-2516.

\(<Rn>\) For encoding A1: is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

\(!\) Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

\(<\text{dreglist}>\) Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.
Operation for all encodings

The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.
F8.1.9 SHA1C

SHA1 hash update (choose).

A1

F8.1.19 VABA

Vector Absolute Difference and Accumulate subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see Conditional execution on page F2-2517.

Assembler symbols

<>
See Standard assembler syntax fields on page F2-2516. An A32 VABA or VABAL instruction must be unconditional. ARM strongly recommends that a T32 VABA or VABAL instruction is unconditional, see Conditional execution on page F2-2517.

<>
See Standard assembler syntax fields on page F2-2516.

<dt>
Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
S8  when U = 0, size = 00
S16 when U = 0, size = 01
S32 when U = 0, size = 10
U8  when U = 1, size = 00
U16 when U = 1, size = 01
U32 when U = 1, size = 10
It is reserved when:
- U = 0, size = 11.
- U = 1, size = 11.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Do>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<On>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Om>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Elem[Din[n+r],e,esize];
        op2 = Elem[Din[m+r],e,esize];
        absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
        if long_destination then
            Elem[Q(d>1),e,2*esize] = Elem[Qin[d>1],e,2*esize] + absdiff;
        else
            Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + absdiff;
F8.1.20   VABAL

Vector Absolute Difference and Accumulate Long subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand elements are all integers of the same length, and the result elements are double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see Conditional execution on page F2-2517.

```
F8.1.25 VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see Conditional execution on page F2-2517.

This instruction is used by the alias VACLE. See the Alias conditions on page F8-3317 table for details of when each alias is preferred.

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>VACLE</td>
<td>Never</td>
</tr>
</tbody>
</table>

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F2-2516. An A32 VACGE, VACGT, VACLE, or VACLT instruction must be unconditional. ARM strongly recommends that a T32 VACGE, VACGT, VACLE, or VACLT instruction is unconditional, see *Conditional execution* on page F2-2517.
- `<q>` See *Standard assembler syntax fields* on page F2-2516.
- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <Qd>*2.
- `<Qn>` Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- `<Qm>` Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = FPAbs(Elem[D[n+r],e,esize]);  op2 = FPAbs(Elem[D[m+r],e,esize]);
            if or_equal then
                test_passed = FPCompareGE(op1, op2, StandardFPSCRValue());
            else
                test_passed = FPCompareGT(op1, op2, StandardFPSCRValue());
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
F8.1.26 VACLE

Vector Absolute Compare Less Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is an alias of the VACGE instruction. This means that:

- The encodings in this description are named to match the encodings of VACGE.
- The description of VACGE gives the operational pseudocode for this instruction.

Assembler symbols

- `<Dm>` is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- `<Qn>` is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- `<Qm>` is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as `<Qm>*2`.
- `<Qn>` is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as `<Qn>*2`.
- `<<c>` See Standard assembler syntax fields on page F2-2516. An A32 VACGE, VACGT, VACLE, or VACLT instruction must be unconditional. ARM strongly recommends that a T32 VACGE, VACGT, VACLE, or VACLT instruction is unconditional, see Conditional execution on page F2-2517.
- `<<op>` See Standard assembler syntax fields on page F2-2516.
- `<Qd>` is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as `<Qd>*2`.
- `<Dd>` is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation for all encodings

The description of VACGE gives the operational pseudocode for this instruction.
F8.1.27  VACGT

Vector Absolute Compare Greater Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see Conditional execution on page F2-2517.

This instruction is used by the alias VACLT. See the Alias conditions on page F8-3321 table for details of when each alias is preferred.

Assembler symbols

<i>c</i>  
See Standard assembler syntax fields on page F2-2516. An A32 Advanced SIMD <code>VADD</code> instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD <code>VADD</code> instruction is unconditional, see Conditional execution on page F2-2517.

<i>q</i>  
See Standard assembler syntax fields on page F2-2516.

<i>dt</i>  
Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:

- I8 when size = 00
- I16 when size = 01
- I32 when size = 10
- I64 when size = 11

<i>Qd</i>  
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <code>Qd</code>*2.

<i>Qn</i>  
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <code>Qn</code>*2.

<i>Qm</i>  
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <code>Qm</code>*2.

<i>Dd</i>  
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<i>Dn</i>  
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<i>Mm</i>  
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations(); CheckAdvSIMDEnabled();
   for r = 0 to regs-1
      for e = 0 to elements-1
         Elem[D[r]+e,esize] = Elem[D[r]+e,esize] + Elem[D[r]+e,esize];
F8.1.31 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see VRADDHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

            op1 = Int(Elem[Din[n],e,esize], unsigned);
        result = op1 + Int(Elem[Din[m],e,esize],unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```
F8.1.34 VAND (immediate)

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector.

This instruction is an alias of the VBIC (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VBIC (immediate).
- The description of VBIC (immediate) gives the operational pseudocode for this instruction.

\[
\text{VAND}\{<c>\}{<q>}.<dt> \{<Qd>,\} <Qd>, #<imm>
\]
is equivalent to
\[
\text{VBIC}<{\langle}\rangle}{\langle{q}\rangle} . {\langle}\text{dt}\rangle} \langle{Qd}\rangle, \#-<\text{imm}>
\]
and is never the preferred disassembly.

**Assembler symbols**

<\langle\rangle> See *Standard assembler syntax fields on page F2-2516*. An A32 VORR instruction must be unconditional. ARM strongly recommends that a T32 VORR instruction is unconditional, see *Conditional execution on page F2-2517*.

<\langle{q}\rangle> See *Standard assembler syntax fields on page F2-2516*.

<\langle\text{dt}\rangle> The data type used for <\text{imm}>. It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.

<\langle{Qd}\rangle> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <\langle{Qd}\rangle>*2.

<\langle{Dd}\rangle> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<\langle\text{imm}\rangle> Is a constant of the type specified by <\langle\text{dt}\rangle> that is replicated to fill the destination register. For details of the range of constants available and the encoding of <\langle\text{dt}\rangle> and <\langle\text{imm}\rangle>, see *One register and a modified immediate value on page F5-2606*.

**Operation for all encodings**

The description of VBIC (immediate) gives the operational pseudocode for this instruction.
F8.1.35 VAND (register)

Vector Bitwise AND (register) performs a bitwise AND operation between two registers, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

64-bit SIMD vector variant

Applies when Q = 0.

\[
\text{VAND}\{<c>\}{<q>}{.<dt>} {<Dd>,} <Dn>, <Dm>
\]

128-bit SIMD vector variant

Applies when Q = 1.

\[
\text{VAND}\{<c>\}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>
\]

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
\[d = \text{UInt}(D:Vd); \ n = \text{UInt}(N:Vn); \ m = \text{UInt}(M:Vm); \ \text{regs} = \text{if} \ Q == '0' \ \text{then} \ 1 \ \text{else} \ 2;\]

64-bit SIMD vector variant

Applies when Q = 0.

\[
\text{VAND}\{<c>\}{<q>}{.<dt>} {<Dd>,} <Dn>, <Dm>
\]

128-bit SIMD vector variant

Applies when Q = 1.

\[
\text{VAND}\{<c>\}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>
\]

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
\[d = \text{UInt}(D:Vd); \ n = \text{UInt}(N:Vn); \ m = \text{UInt}(M:Vm); \ \text{regs} = \text{if} \ Q == '0' \ \text{then} \ 1 \ \text{else} \ 2;\]
Assembler symbols

<i>&lt;c&gt;</i> See Standard assembler syntax fields on page F2-2516. An A32 <i>VAND</i> instruction must be unconditional. ARM strongly recommends that a T32 <i>VAND</i> instruction is unconditional, see Conditional execution on page F2-2517.

<i>&lt;p&gt;</i> See Standard assembler syntax fields on page F2-2516.

<i>&lt;dt&gt;</i> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<i>&lt;Qd&gt;</i> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <i>&lt;Qd&gt;</i>*2.

<i>&lt;Qn&gt;</i> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <i>&lt;Qn&gt;</i>*2.

<i>&lt;Qm&gt;</i> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <i>&lt;Qm&gt;</i>*2.

<i>&lt;Dd&gt;</i> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<i>&lt;Dn&gt;</i> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<i>&lt;Dm&gt;</i> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```
F8.1.36 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

This instruction is used by the alias VAND (immediate). See the Alias conditions on page F8-3340 table for details of when each alias is preferred.

Assembler symbols

See [Standard assembler syntax fields on page F2-2516](#). An A32 VBIC instruction must be unconditional. ARM strongly recommends that a T32 VBIC instruction is unconditional, see "[Conditional execution on page F2-2517](#)".

<op>
See [Standard assembler syntax fields on page F2-2516](#).

<dt>
An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as \(<Qd>\)*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \(<Qn>\)*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \(<Qm>\)*2.

<Qd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Qm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND NOT(D[m+r]);
```
F8.1.38 VBIF

Vector Bitwise Insert if False inserts each bit from the first source register into the destination register if the corresponding bit of the second source register is 0, otherwise leaves the bit in the destination register unchanged.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

F8.1.41  VCEQ (Immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

Assembler symbols

See Standard assembler syntax fields on page F2-2516. An A32 VCEQ instruction must be unconditional. ARM strongly recommends that a T32 VCEQ instruction is unconditional, see Conditional execution on page F2-2517.

The data types for the elements of the operands. It must be one of:

- I8  Encoding T1/A1, size = 0b00.
- I16 Encoding T1/A1, size = 0b01.
- I32 Encoding T1/A1, size = 0b10.
- F32 Encoding T2/A2, sz = 0.

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <Qd>*2.

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```assembly
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize];  op2 = Elem[D[m+r],e,esize];
            if int_operation then
                test_passed = (op1 == op2);
            else
                test_passed = FPCompareEQ(op1, op2, StandardFPSCRValue());
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```
F8.1.43 VCGE (Immediate #0)

Vector Compare Greater Than or Equal to Zero takes each element in a vector, and compares it with zero. If it is greater than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

</thead>
<tbody>
<tr>
<td>VCLT (register)</td>
<td>Never</td>
</tr>
</tbody>
</table>

Assembler symbols

See Standard assembler syntax fields on page F2-2516. An A32 VCGT instruction must be unconditional. ARM strongly recommends that a T32 VCGT instruction is unconditional, see Conditional execution on page F2-2517.

Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:

- S8 when U = 0, size = 00
- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- U8 when U = 1, size = 00
- U16 when U = 1, size = 01
- U32 when U = 1, size = 10

It is RESERVED when:
- U = 0, size = 11.
- U = 1, size = 11.

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <Qd>*2.

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

e enumeration VCGType {VCGType_signed, VCGType_unsigned, VCGType_fp};

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[r+n],e,esize];  op2 = Elem[D[r+m],e,esize];
            case type of
                when VCGType_signed    test_passed = (SInt(op1) > SInt(op2));

when VCGTtype_unsigned test_passed = (UInt(op1) > UInt(op2));
when VCGTtype_fp test_passed = FPCompareGT(op1, op2, StandardFPSCRValue());
Elem[D[d]+e,esize] = if test_passed then Ones(esize) else Zeros(esize);
F8.1.47 VCLE (Immediate #0)

Vector Compare Less Than or Equal to Zero takes each element in a vector, and compares it with zero. If it is less than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

         if floating_point then
            bits(esize) zero = FPZero('0');
            test_passed = FPCompareGT(zero, Elem[D[m+r],e,esize], StandardFPSCRValue());
         else
            test_passed = (SInt(Elem[D[m+r],e,esize]) < 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
F8.1.51   VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is an alias of the VCGT (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VCGT (register).
- The description of VCGT (register) gives the operational pseudocode for this instruction.

**Assembler symbols**

- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- `<Qm>` Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as `<Qm>*2.`
- `<Qn>` Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as `<Qn>*2.`
- `<c>` See Standard assembler syntax fields on page F2-2516. An A32 VCGT instruction must be unconditional. ARM strongly recommends that a T32 VCGT instruction is unconditional, see Conditional execution on page F2-2517.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<dt>` Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
  - `S8` when `U = 0`, size = `00`
  - `S16` when `U = 0`, size = `01`
  - `S32` when `U = 0`, size = `10`
  - `U8` when `U = 1`, size = `00`
  - `U16` when `U = 1`, size = `01`
  - `U32` when `U = 1`, size = `10`

  It is reserved when:
  - `U = 0`, size = `11`.
  - `U = 1`, size = `11`.

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as `<Qd>*2.`
- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

**Operation for all encodings**

The description of VCGT (register) gives the operational pseudocode for this instruction.
F8.1.52   VCLZ

Vector Count Leading Zeros counts the number of consecutive zeros, starting from the most significant bit, in each element in a vector, and places the results in a second vector.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

**Notes for all encodings**
For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2516.
- `<q>` See Standard assembler syntax fields on page F2-2516.
- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- `<Sm>` Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

VOMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if dp_operation then
        bits(64) op64 = if with_zero then FPZero('0') else D[m];
        FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
    else
        bits(32) op32 = if with_zero then FPZero('0') else S[m];
        FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
F8.1.54 VCMPE

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the PSTATE, {N, Z, C, V} Condition flags by a subsequent VMRS instruction.

It raises an Invalid Operation exception if either operand is any type of NaN, or if either operand is a signaling NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

F8.1.57 VCVT (between half-precision and single-precision, Advanced SIMD)

Vector Convert between half-precision and single-precision converts each element in a vector from single-precision to half-precision floating-point, or from half-precision to single-precision, and places the results in a second vector. The vector elements must be 32-bit floating-point numbers, or 16-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

A1

Encoding

Applies when op = 0.

VCVT{<c>}{<q>}.F16.F32 <Dd>, <Qm> // Encoded as op = 0

Encoding

Applies when op = 1.

Decode for all variants of this encoding

if size != '01' then UNDEFINED;
half_to_single = (op == '1');
if half_to_single && Vd<0> == '1' then UNDEFINED;
if !half_to_single && Vm<0> == '1' then UNDEFINED;
esize = 16; elements = 4;
m = UInt(M:Vm); d = UInt(D:Vd);

T1

Encoding

Applies when op = 0.

VCVT{<c>}{<q>}.F16.F32 <Dd>, <Qm> // Encoded as op = 0

Encoding

Applies when op = 1.

VCVT{<c>}{<q>}.F32.F16 <Qd>, <Dm> // Encoded as op = 1
Decode for all variants of this encoding

if size != '01' then UNDEFINED;
half_to_single = (op == '1');
if half_to_single & Vd<0> == '1' then UNDEFINED;
if !half_to_single & Vm<0> == '1' then UNDEFINED;
esize = 16; elements = 4;
m = UInt(M:Vm); d = UInt(D:Vd);

Assembler symbols

See Standard assembler syntax fields on page F2-2516. An A32 VCVT instruction must be unconditional. ARM strongly recommends that a T32 VCVT instruction is unconditional, see Conditional execution on page F2-2517.

<op> See Standard assembler syntax fields on page F2-2516.

<qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <qd>*2.

<qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

qd Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

qm Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <qm>*2.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    if half_to_single then
      Elem[Q[d>>1],e,32] = FPConvert(Elem[Din[m],e,16], StandardFPSCRValue());
    else
      Elem[D[d],e,16] = FPConvert(Elem[Qin[m>>1],e,32], StandardFPSCRValue());
F8.1.58 VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

                     FPRounding_TIEEVEN);
  Elem[D[d+r],e,esize] = result;
F8.1.62 VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The floating-point value can be single-precision or double-precision.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

**Notes for all encodings**
For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VCVT (between floating-point and fixed-point) on page J1-5424.

**Assembler symbols**

- \( \langle c \rangle \)
  See Standard assembler syntax fields on page F2-2516.
- \( \langle q \rangle \)
  See Standard assembler syntax fields on page F2-2516.
- \( \langle \text{dt} \rangle \)
  Is the data type for the fixed-point number, encoded in the "U:sx" field. It can have the following values:

  - \( S16 \) when \( U = 0, \) \( sx = 0 \)
  - \( S32 \) when \( U = 0, \) \( sx = 1 \)
  - \( U16 \) when \( U = 1, \) \( sx = 0 \)
  - \( U32 \) when \( U = 1, \) \( sx = 1 \)

- \( \langle \text{Sdm} \rangle \)
  Is the 32-bit name of the SIMD&FP destination and source register, encoded in the "Vd:D" field.

- \( \langle \text{Ddm} \rangle \)
  Is the 64-bit name of the SIMD&FP destination and source register, encoded in the "D:Vd" field.
The number of fraction bits in the fixed-point number:

- If $dt$ is S16 or U16, $<fbits>$ must be in the range 0-16. $(16 - <fbits>)$ is encoded in $[imm_4, i]$.
- If $dt$ is S32 or U32, $<fbits>$ must be in the range 1-32. $(32 - <fbits>)$ is encoded in $[imm_4, i]$.

**Assembler symbols**

\(^{<q>}\) See Standard assembler syntax fields on page F2-2516.
<dt>  Is the data type for the elements of the destination, encoded in the "op" field. It can have the following values:
    S32  when op = 0
    U32  when op = 1

<sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

<dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
if dp_operation then
    S[d] = FPToFixed(D[m], 0, unsigned, FPSCR, rounding);
else
    S[d] = FPToFixed(S[m], 0, unsigned, FPSCR, rounding);
```
F8.1.68  VCVTN (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest converts each element in a vector from floating-point to integer using the Round to Nearest rounding mode, and places the results in a second vector.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit integers. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

F8.1.73 VCVTT

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.     else
        S[d] = FPDiv(S[n], S[m], FPSCR);
F8.1.75  VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<8> See Standard assembler syntax fields on page F2-2516. ARM strongly recommends that any VDUP instruction is unconditional, see Conditional execution on page F2-2517.

<q> See Standard assembler syntax fields on page F2-2516.

<size> The data size for the elements of the destination vector. It must be one of:

8  Encoded as [b, e] = 0b10.
16  Encoded as [b, e] = 0b01.
32  Encoded as [b, e] = 0b00.

<Qd> The destination vector for a quadword operation.

<Dd> The destination vector for a doubleword operation.

<Rt> The ARM source register.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  scalar = R[t]<esize-1:0>;
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = scalar;
F8.1.76 VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see Advanced SIMD scalars on page F5-2596.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2516. An A32 VDUP instruction must be unconditional. ARM strongly recommends that a T32 VDUP instruction is unconditional, see Conditional execution on page F2-2517.

- `<q>` See Standard assembler syntax fields on page F2-2516.

- `<size>` The data size. It must be one of:
  - 8 Encoded as imm4<0> = '1'. imm4<3:1> encodes the index{x} of the scalar.
  - 16 Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index {x} of the scalar.
  - 32 Encoded as imm4<2:0> = '100'. imm4<3> encodes the index {x} of the scalar.

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.`

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm[x]>` The scalar. For details of how {x} is encoded, see the description of `<size>`.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  scalar = Elem[D[m],index,esize];
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = scalar;
F8.1.77 VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

Assembler symbols

<c>
See Standard assembler syntax fields on page F2-2516. An A32 VEOR instruction must be unconditional. ARM strongly recommends that a T32 VEOR instruction is unconditional, see Conditional execution on page F2-2517.

<q>
See Standard assembler syntax fields on page F2-2516.

<dt>
An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field, as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
F8.1.78 VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows an example of the operation of VEXT doubleword operation for imm = 3.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

This instruction is used by the alias VEXT (multibyte elements). See the Alias conditions on page F8-3439 table for details of when each alias is preferred.

\text{else} \\
&D[d] = (D[m]:D[n])<position+63:position>;
\end{align*}
\]
### VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

This instruction is an alias of the VEXT (byte elements) instruction. This means that:

- The encodings in this description are named to match the encodings of VEXT (byte elements).
- The description of VEXT (byte elements) gives the operational pseudocode for this instruction.

#### 64-bit SIMD vector variant

Applies when \( Q = 0 \).

\[
\text{VEXT}\{<c>\}{<q>}.<\text{size}>\{<Dd>,\} <Dn>, <Dm>, \#<\text{imm}>
\]

is equivalent to

\[
\text{VEXT}\{<c>\}{<q>}.8\{<Dd>,\} <Dn>, <Dm>, \#<\text{imm}(\text{size}/8)>
\]

and is never the preferred disassembly.

#### 128-bit SIMD vector variant

Applies when \( Q = 1 \).

\[
\text{VEXT}\{<c>\}{<q>}.<\text{size}>\{<Qd>,\} <Qn>, <Qm>, \#<\text{imm}>
\]

is equivalent to

\[
\text{VEXT}\{<c>\}{<q>}.8\{<Qd>,\} <Qn>, <Qm>, \#<\text{imm}(\text{size}/8)>
\]

and is never the preferred disassembly.

#### T1

\[
\text{VEXT}\{<c>\}{<q>}.<\text{size}>\{<Dd>,\} <Dn>, <Dm>, \#<\text{imm}>
\]

is equivalent to

\[
\text{VEXT}\{<c>\}{<q>}.8\{<Dd>,\} <Dn>, <Dm>, \#<\text{imm}(\text{size}/8)>
\]

and is never the preferred disassembly.
is equivalent to

\texttt{VEXT\langle c\rangle\{\langle q\rangle\}.8 \{\langle Qd\rangle, \langle Qn\rangle, \langle Qm\rangle, \#imm\times(size/8)\}}

and is never the preferred disassembly.

**Assembler symbols**

- \texttt{\langle c\rangle} See [Standard assembler syntax fields on page F2-2516](#). An A32 \texttt{VEXT} instruction must be unconditional. ARM strongly recommends that a T32 \texttt{VEXT} instruction is unconditional, see [Conditional execution on page F2-2517](#).

- \texttt{\langle q\rangle} See [Standard assembler syntax fields on page F2-2516](#).

- \texttt{\langle size\rangle} For the 64-bit SIMD vector variant: is the size of the operation, and can be one of 16 or 32. For the 128-bit SIMD vector variant: is the size of the operation, and can be one of 16, 32 or 64.

- \texttt{\langle Qd\rangle} Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \texttt{\langle Qd\rangle*2}.

- \texttt{\langle Qn\rangle} Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \texttt{\langle Qn\rangle*2}.

- \texttt{\langle Qm\rangle} Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \texttt{\langle Qm\rangle*2}.

- \texttt{\langle Dd\rangle} Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- \texttt{\langle Dn\rangle} Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

- \texttt{\langle Dm\rangle} Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

- \texttt{\langle imm\rangle} For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to \((128/\langle size\rangle)-1\). For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to \((64/\langle size\rangle)-1\).

**Operation for all encodings**

The description of \texttt{VEXT (byte elements)} gives the operational pseudocode for this instruction.
VFMA

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

<> See Standard assembler syntax fields on page F2-2516.

<sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.

<sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

<dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if dp_operation then
        op64 = if op1_neg then FPNeg(D[n]) else D[n];
        D[d] = FPMulAdd(FPNeg(D[d]), op64, D[m], FPSCR);
    else
        op32 = if op1_neg then FPNeg(S[n]) else S[n];
        S[d] = FPMulAdd(FPNeg(S[d]), op32, S[m], FPSCR);
F8.1.84 \textbf{VHADD}

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. For rounded results, see \textit{VRHADD}).

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPCR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see \textit{Enabling Advanced SIMD and floating-point support} on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see \textit{Conditional execution} on page F2-2517.

Notes for all encodings
For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols
<br>
See Standard assembler syntax fields on page F2-2516. An A32 VLDI instruction must be unconditional. ARM strongly recommends that a T32 VLDI instruction is unconditional, see Conditional execution on page F2-2517.

<op>
See Standard assembler syntax fields on page F2-2516.

<size>
The data size. It must be one of:
  8    Encoded as size = 0b00.
  16   Encoded as size = 0b01.
  32   Encoded as size = 0b10.

<list>
The register containing the element to load. It must be {<Dd[x]>}. The register <Dd> is encoded in D:Vd.

<Rn>
Contains the base address for the access.

<align>
The alignment. It can be one of:
  16   2-byte alignment, available only if <size> is 16.
32  4-byte alignment, available only if <size> is 32.

omitted Standard alignment, see Unaligned data access on page E2-2435.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode on page F5-2615.

<Rm> Contains an address offset applied after the access.

For more information about <Rm>, !, and <Rm>, see Advanced SIMD addressing mode on page F5-2615.

Table F8-1 shows the encoding of index and alignment for the different <size> values.

wback = (m != 15);  register_index = (m != 15 & m != 11);
if n == 15 || d+regs > 32 then UNPREDICTABLE;

**Notes for all encodings**

For information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD1 (single element to all lanes) on page J1-5425.

**Assembler symbols**

<c> See Standard assembler syntax fields on page F2-2516. An A32 VLD1 instruction must be unconditional. ARM strongly recommends that a T32 VLD1 instruction is unconditional, see Conditional execution on page F2-2517.

<q> See Standard assembler syntax fields on page F2-2516.

<size> The data size. It must be one of:

- 8  Encoded as size = 0b00.
- 16 Encoded as size = 0b01.
- 32 Encoded as size = 0b10.

<list> The list of registers to load. It must be one of:

{<Dd[]>}  Encoded as D:Vd = <Dd>, T = 0.
{<Dd[]>, <Dd+1[]>}  Encoded as D:Vd = <Dd>, T = 1.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:

- 16  2-byte alignment, available only if <size> is 16, encoded as a = 1.
- 32  4-byte alignment, available only if <size> is 32, encoded as a = 1.
- omitted Standard alignment, see Unaligned data access on page E2-2435. Encoded as a = 0.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode on page F5-2615.

<RM> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see Advanced SIMD addressing mode on page F5-2615.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then
if register_index then
  R[n] = R[n] + R[m];
else
  R[n] = R[n] + ebytes;
bits(64) replicated_element = Replicate(MemU[address,ebytes]);
for r = 0 to regs-1
  D[d+r] = replicated_element;
F8.1.88   VLD1 (multiple single elements)

Load multiple single 1-element structures to one, two, three, or four registers loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see Advanced SIMD addressing mode on page F5-2615.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

Notes for all encodings
For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD4 (single 4-element structure to one lane) on page J1-5427.

Assembler symbols

\(<c>\)
See Standard assembler syntax fields on page F2-2516. An A32 VLD4 instruction must be unconditional. ARM strongly recommends that a T32 VLD4 instruction is unconditional, see Conditional execution on page F2-2517.

\(<q>\)
See Standard assembler syntax fields on page F2-2516.

\(<\text{size}>\)
The data size. It must be one of:

8 Encoded as size = 0b00.
16 Encoded as size = 0b01.
32 Encoded as size = 0b10.

\(<\text{list}>\)
The registers containing the structure. Encoded with D:Vd = <Dd>. It must be one of:

\(<\text{Dd}[x]>\), \(<\text{Dd}+1[x]>\), \(<\text{Dd}+2[x]>\), \(<\text{Dd}+3[x]>\)
Single-spaced registers, see Table F8-4 on page F8-3485.

\(<\text{Dd}[x]>\), \(<\text{Dd}+2[x]>\), \(<\text{Dd}+4[x]>\), \(<\text{Dd}+6[x]>\)
Double-spaced registers, see Table F8-4 on page F8-3485.
Not available if <size> == 8.

<Rn> The base address for the access.

<align> The alignment. It can be:
32  4-byte alignment, available only if <size> is 8.
64  8-byte alignment, available only if <size> is 16 or 32.
128 16-byte alignment, available only if <size> is 32.
omitted Standard alignment, see Unaligned data access on page E2-2435.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode on page F5-2615.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see Advanced SIMD addressing mode on page F5-2615.

### Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
        Elem[D[d], index] = MemU[address,ebytes];
        Elem[D[d2], index] = MemU[address+ebytes,ebytes];
        Elem[D[d3], index] = MemU[address+2*ebytes,ebytes];
        Elem[D[d4], index] = MemU[address+3*ebytes,ebytes];
```
F8.1.96  VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode see Advanced SIMD addressing mode on page F5-2615.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see Conditional execution on page F2-2517.

Assembler symbols

<
See Standard assembler syntax fields on page F2-2516.
определение>
See Standard assembler syntax fields on page F2-2516.
<size>
An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
<s8n>
For encoding A1 and A2: is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
!<s8n>
Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<reglist>
Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
<dreglist>
Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            \[\text{remaining code}\]
word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
// Combine the word-aligned words in the correct order for current endianness.
D[d+r] = if BigEndian() then word1:word2 else word2:word1;
F8.1.99  VLDR

Load SIMD&FP register loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-3914.
