In this document, where the term ARM is used to refer to the company it means “ARM or any of its subsidiaries as appropriate”.

—— Note ————

• The term ARM can refer to versions of the ARM architecture, for example ARMv8 refers to version 8 of the ARM architecture. The context makes it clear when the term is used in this way.

• This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

—— Web Address ————

http://www.arm.com

—— Limitations of issue A.f ————

This issue A.f of the ARMv8 Architecture Reference Manual contains many improvements and corrections. However, as indicated by its beta status, it remains work-in-progress. Validation of this document has identified the following issues that ARM will address in the next issue:

• Compared to changes made in issue A.e:
  — The ARM Generic Interrupt Controller (GICv3) CPU interface register descriptions in Chapter D7 AArch64 System Register Descriptions and Chapter G6 AArch32 System Register Descriptions remain work-in-progress. Contact ARM if you require more information about these registers.
  — We are in the process of improving the introductory A64 instruction descriptions in Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions. However, this work is incomplete and many instructions still have only a minimal introduction.
  — The subsections on Traps and enables in the System register descriptions in Chapter D7 AArch64 System Register Descriptions and Chapter G6 AArch32 System Register Descriptions that were added in issue A.d have been significantly revised. These revisions have not had the same level of review as the rest of the manual.

• We are working to improve the descriptions of register reset behavior in the register descriptions throughout this manual. This remains work-in-progress for the GICv3 CPU interface registers, debug registers, and memory-mapped registers.

—— Note ————

Except for the registers mentioned in this bullet, the register descriptions do not give a clear indication of when any stated reset values apply. PE state on reset to AArch64 state on page D1-1512 summarizes the requirements for a reset into AArch64 state, but there is no equivalent summary for a reset into AArch32 state. ————

• There have been additions to the Performance Monitors Extension described in Chapter D5 The Performance Monitors Extension. These additions include the definition of additional events, described in Chapter D5, and additional recommended IMPLEMENTATION DEFINED events, described in Appendix J3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events. These additions have had only very limited review.

B2.10 Synchronization and semaphores ................................... B2-107

**Part C**  
**The AArch64 Instruction Set**

**Chapter C1**  
The A64 Instruction Set  
C1.1 Introduction ....................................................................... C1-120  
C1.2 Structure of the A64 assembler language ............................ C1-121  
C1.3 Address generation .......................................................... C1-126  
C1.4 Instruction aliases ............................................................ C1-129

**Chapter C2**  
About the A64 Instruction Descriptions  
C2.1 Understanding the A64 instruction descriptions .................... C2-132

**Chapter C3**  
A64 Instruction Set Overview  
C3.1 Branches, Exception generating, and System instructions .......... C3-136  
C3.2 Loads and stores ............................................................. C3-140  
C3.3 Data processing - immediate ............................................. C3-151  
C3.4 Data processing - register ................................................ C3-156  
C3.5 Data processing - SIMD and floating-point ............................ C3-163

**Chapter C4**  
A64 Instruction Set Encoding  
C4.1 A64 instruction index by encoding ....................................... C4-184  
C4.2 Branches, exception generating and system instructions .......... C4-185  
C4.3 Loads and stores ............................................................. C4-188  
C4.4 Data processing - immediate ............................................. C4-205  
C4.5 Data processing - register ................................................ C4-208  
C4.6 Data processing, SIMD and floating-point ............................. C4-215

**Chapter C5**  
The A64 System Instruction Class  
C5.1 About the System instruction and System register descriptions .... C5-242  
C5.2 The System instruction class encoding space ........................ C5-244  
C5.3 Special-purpose registers .................................................. C5-264  
C5.4 A64 system instructions for cache maintenance .................... C5-315  
C5.5 A64 system instructions for address translation .................... C5-331  
C5.6 A64 system instructions for TLB maintenance ....................... C5-344

**Chapter C6**  
A64 Base Instruction Descriptions  
C6.1 Introduction ...................................................................... C6-398  
C6.2 Register size ..................................................................... C6-399  
C6.3 Use of the PC ................................................................. C6-400  
C6.4 Use of the stack pointer .................................................... C6-401  
C6.5 Condition flags and related instructions ............................... C6-402  
C6.6 Alphabetical list of instructions ......................................... C6-403

**Chapter C7**  
A64 Advanced SIMD and Floating-point Instruction Descriptions  
C7.1 Introduction ...................................................................... C7-806
Part D  The AArch64 System Level Architecture

Chapter D1  The AArch64 System Level Programmers' Model

D1.1 Exception levels .......................................................... D1-1490
D1.2 Exception terminology .................................................. D1-1491
D1.3 Execution state ............................................................ D1-1493
D1.4 Security state ............................................................... D1-1494
D1.5 Virtualization ............................................................... D1-1496
D1.6 Registers for instruction processing and exception handling . D1-1499
D1.7 Process state, PSTATE .................................................. D1-1506
D1.8 Program counter and stack pointer alignment .................... D1-1509
D1.9 Reset ................................................................. D1-1511
D1.10 Exception entry ........................................................ D1-1516
D1.11 Exception return ....................................................... D1-1533
D1.12 The Exception level hierarchy ....................................... D1-1538
D1.13 Synchronous exception types, routing and priorities .......... D1-1545
D1.14 Asynchronous exception types, routing, masking and priorities D1-1552
D1.15 Configurable instruction enables and disables, and trap controls D1-1558
D1.16 System calls ............................................................. D1-1593
D1.17 Mechanisms for entering a low-power state ..................... D1-1595
D1.18 Self-hosted debug ..................................................... D1-1601
D1.19 The Performance Monitors Extension ............................ D1-1603
D1.20 Interprocessing ......................................................... D1-1604
D1.21 The effect of implementation choices on the programmers' model D1-1616

Chapter D2  AArch64 Self-hosted Debug

D2.1 About debug exceptions ............................................. D2-1623
D2.2 The debug exception enable controls ............................. D2-1626
D2.3 Routing debug exceptions .......................................... D2-1627
D2.4 Enabling debug exceptions from the current Exception level and Security state D2-1629
D2.5 The effect of powerdown on debug exceptions .................. D2-1631
D2.6 Summary of the routing and enabling of debug exceptions . D2-1632
D2.7 Pseudocode description of debug exceptions .................. D2-1634
D2.8 Software Breakpoint Instruction exceptions .................... D2-1636
D2.9 breakpoint exceptions ............................................... D2-1638
D2.10 Watchpoint exceptions ............................................. D2-1656
D2.11 Vector Catch exceptions ........................................... D2-1670
D2.12 Software Step exceptions ......................................... D2-1671
D2.13 Synchronization and debug exceptions ........................ D2-1686

Chapter D3  The AArch64 System Level Memory Model

D3.1 About the memory system architecture .......................... D3-1688
D3.2 Address space .......................................................... D3-1689
D3.3 Mixed-endian support ................................................ D3-1690
D3.4 Cache support ........................................................... D3-1691
D3.5 External aborts .......................................................... D3-1711
D3.6 Memory barrier instructions ....................................... D3-1713
D3.7 Pseudocode description of general memory system instructions D3-1714

Chapter D4  The AArch64 Virtual Memory System Architecture

D4.1 About the Virtual Memory System Architecture (VMSA)  .......... D4-1726
D4.2 The VMSAv8-64 address translation system ..................... D4-1728
D4.3 Translation table walk examples .................................. D4-1779

## Part F  The AArch32 Instruction Sets

### Chapter F1  The AArch32 Instruction Sets Overview
- F1.1 Support for instructions in different versions of the ARM architecture ........................................... F1-2478
- F1.2 Unified Assembler Language ............................................................................................................. F1-2479
- F1.3 Branch instructions ............................................................................................................................ F1-2481
- F1.4 Data-processing instructions .............................................................................................................. F1-2482
- F1.5 PSTATE and banked register access instructions .................................................................................. F1-2490
- F1.6 Load/store instructions ....................................................................................................................... F1-2491
- F1.7 Load/store multiple instructions .......................................................................................................... F1-2493
- F1.8 Miscellaneous instructions ............................................................................................................... F1-2494
- F1.9 Exception-generating and exception-handling instructions ............................................................... F1-2495
- F1.10 Coprocessor instructions .................................................................................................................. F1-2496
- F1.11 Advanced SIMD and floating-point load/store instructions .......................................................... F1-2497
- F1.12 Advanced SIMD and floating-point register transfer instructions ................................................. F1-2499
- F1.13 Advanced SIMD data-processing instructions ................................................................................ F1-2500
- F1.14 Floating-point data-processing instructions ................................................................................... F1-2508

### Chapter F2  About the T32 and A32 Instruction Descriptions
- F2.1 Format of instruction descriptions ...................................................................................................... F2-2512
- F2.2 Standard assembler syntax fields ....................................................................................................... F2-2516
- F2.3 Conditional execution ......................................................................................................................... F2-2517
- F2.4 Shifts applied to a register .................................................................................................................. F2-2520
- F2.5 Memory accesses ................................................................................................................................ F2-2523
- F2.6 Encoding of lists of general-purpose registers and the PC ................................................................ F2-2524
- F2.7 Additional pseudocode support for instruction descriptions ............................................................ F2-2525

### Chapter F3  T32 Base Instruction Set Encoding
- F3.1 T32 instruction set encoding .............................................................................................................. F3-2528
- F3.2 16-bit T32 instruction encoding ........................................................................................................ F3-2531
- F3.3 32-bit T32 instruction encoding ......................................................................................................... F3-2538

### Chapter F4  A32 Base Instruction Set Encoding
- F4.1 A32 instruction set encoding .............................................................................................................. F4-2562
- F4.2 Data-processing and miscellaneous instructions .................................................................................. F4-2565
- F4.3 Load/store word and unsigned byte .................................................................................................... F4-2577
- F4.4 Media instructions ............................................................................................................................... F4-2578
- F4.5 Branch, branch with link, and block data transfer ............................................................................. F4-2583
- F4.6 Coprocessor instructions, and Supervisor Call .................................................................................. F4-2584
- F4.7 Unconditional instructions ................................................................................................................ F4-2585

### Chapter F5  T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings
- F5.1 Overview ............................................................................................................................................... F5-2590
- F5.2 Advanced SIMD and floating-point instruction syntax ..................................................................... F5-2591
- F5.3 Register encoding ............................................................................................................................... F5-2595
- F5.4 Advanced SIMD data-processing instructions .................................................................................. F5-2597
- F5.5 Floating-point data-processing instructions ..................................................................................... F5-2609
- F5.6 Advanced SIMD and floating-point register load/store instructions .............................................. F5-2612
- F5.7 Advanced SIMD element or structure load/store instructions ....................................................... F5-2613
- F5.8 8, 16, and 32-bit transfers accessing the SIMD and floating-point register file ................................. F5-2616
- F5.9 64-bit transfers accessing the SIMD and floating-point register file ............................................... F5-2617

### Chapter F6  ARMv8 Changes to the T32 and A32 Instruction Sets
- F6.1 The A32 and T32 instruction sets ....................................................................................................... F6-2620
- F6.2 Partial depreciation of IT ..................................................................................................................... F6-2621
- F6.3 New A32 and T32 Load-Acquire/Store-Release instructions ............................................................... F6-2622

Preface

This preface introduces the ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile. It contains the following sections:

• About this manual on page xvi.
• Using this manual on page xviii.
• Conventions on page xxiii.
• Additional reading on page xxv.
• Feedback on page xxvi.

--- Note ---

This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.
About this manual

This manual describes the ARM® architecture v8, ARMv8. The architecture describes the operation of an ARMv8-A Processing element (PE), and this manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.
- The instruction sets:
  - In AArch32 state, the A32 and T32 instruction sets, that are compatible with earlier versions of the ARM architecture.
  - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This manual covers a single architecture profile, ARMv8-A, that defines a Virtual Memory System Architecture (VMSA).
- The programmers’ model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, that provide high-performance:
  - Single-precision and double-precision floating-point operations.
  - Conversions between double-precision, single-precision, and half-precision floating-point values.
  - Integer, single-precision floating-point, and in A64, double-precision vector operations in all instruction sets.
  - Double-precision floating-point vector operations in the A64 instruction set.
- The security model, that provides two security states to support secure applications.
- The virtualization model, that support the virtualization of Non-secure operation.
- The Debug architecture, that provides software access to debug features.

This manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this manual is not a tutorial for ARM assembler language, nor does it describe ARM assembler language, except at a very basic level. To make effective use of ARM assembler language, read the documentation supplied with the assembler being used.

This manual is organized into parts:

Part A
Provides an introduction to the ARMv8-A architecture, and an overview of the AArch64 and AArch32 Execution states.

Part B
Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers’ model and the memory model.

Part C
Describes the A64 instruction set, that is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as unprivileged execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code.

Part D
Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers’ model and the memory model. This part includes the description of self-hosted debug.

Part E
Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers’ model and the memory model.
— Note —

In AArch32 state, execution at EL0 is execution in User mode.

—— Part F ———

Describes the T32 and A32 instruction sets, that are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the ARM architecture. This part describes the precise effects of each instruction when executed in User mode, described as unprivileged execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code.

— Note —

User mode is the only mode where software execution is unprivileged.

—— Part G ———

Describes the system level view of the AArch32 Execution state, that is generally compatible with earlier versions of the ARM architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the conceptual coprocessor interface to those registers. It also describes the system level view of the programmers’ model and the memory model.

—— Part H ———

Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a Debug Communications Channel (DCC) to a debug host.

—— Part I ———

Describes additional features of the architecture that are not closely coupled to a processing element (PE), and therefore are accessed through memory-mapped interfaces. Some of these features are optional.

—— Appendixes ———

Provide additional information. Some appendixes give information that is not part of the ARMv8 architectural requirements. The cover page of each appendix indicates its status.
Using this manual

The information in this manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the ARMv8-A architecture profile, including its relationship to the other ARM PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32. It contains the following chapter:

Chapter A1 Introduction to the ARMv8 Architecture
Read this for an introduction to the ARMv8 architecture.

Part B, The AArch64 Application Level Architecture

Part B describes the application level view of the architecture in AArch64 state. It contains the following chapters:

Chapter B1 The AArch64 Application Level Programmers’ Model
Read this for an application level description of the programmers’ model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

Chapter B2 The AArch64 Application Level Memory Model
Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about ARM memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, that is used in AArch64 state. It contains the following chapters:

Chapter C1 The A64 Instruction Set
Read this for a description of the A64 instruction set and common instruction operation details.

Chapter C2 About the A64 Instruction Descriptions
Read this to understand the format of the A64 instruction descriptions.

Chapter C3 A64 Instruction Set Overview
Read this for an overview of the individual A64 instructions, that are divided into five functional groups.

Chapter C4 A64 Instruction Set Encoding
Read this for a description of the A64 instruction set encoding.

Chapter C5 The A64 System Instruction Class
Read this for a description of the AArch64 system instructions and register descriptions, and the system instruction class encoding space.

Chapter C6 A64 Base Instruction Descriptions
Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions
Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.
Part D, The AArch64 System Level Architecture

Part D describes the AArch64 the system level view of the architecture. It contains the following chapters:

- **Chapter D1 The AArch64 System Level Programmers’ Model**
  Read this for a description of the AArch64 system level view of the programmers’ model.

- **Chapter D2 AArch64 Self-hosted Debug**
  Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

- **Chapter D3 The AArch64 System Level Memory Model**
  Read this for a description of the AArch64 system level view of the general features of the memory system.

- **Chapter D4 The AArch64 Virtual Memory System Architecture**
  Read this for a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state.

- **Chapter D5 The Performance Monitors Extension**
  Read this for a description of an implementation of the ARM Performance Monitors, that are an optional non-invasive debug component.

- **Chapter D6 The Generic Timer in AArch64 state**
  Read this for a description of an implementation of the AArch64 view of the ARM Generic Timer.

- **Chapter D7 AArch64 System Register Descriptions**
  Read this for an introduction to, and description of, each of the AArch64 system registers.

Part E, The AArch32 Application Level Architecture

Part E describes the AArch32 application level view of the architecture. It contains the following chapters:

- **Chapter E1 The AArch32 Application Level Programmers’ Model**
  Read this for an application level description of the programmers’ model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

- **Chapter E2 The AArch32 Application Level Memory Model**
  Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about ARM memory types, attributes, and memory access controls.

Part F, The AArch32 Instruction Sets

Part F describes the T32 and A32 instruction sets, that are used in AArch32 state. It contains the following chapters:

- **Chapter F1 The AArch32 Instruction Sets Overview**
  Read this for an overview of the T32 and A32 instruction sets.

- **Chapter F2 About the T32 and A32 Instruction Descriptions**
  Read this to understand the format of the T32 and A32 instruction descriptions.

- **Chapter F3 T32 Base Instruction Set Encoding**
  Read this for an introduction to the T32 instruction set and a description of how the T32 instruction set uses the ARM programmers’ model.

- **Chapter F4 A32 Base Instruction Set Encoding**
  Read this for a description of the A32 base instruction set encoding.
Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings
Read this for an overview of the T32 and A32 Advanced SIMD and floating-point instruction sets.

Chapter F6 ARMv8 Changes to the T32 and A32 Instruction Sets
Read this for a summary of the changes that are introduced to the T32 and A32 instruction sets in ARMv8.

Chapter F7 T32 and A32 Base Instruction Set Instruction Descriptions
Read this for a description of each T32 and A32 base instruction.

Chapter F8 T32 and A32 Advanced SIMD and floating-point Instruction Descriptions
Read this for a description of each T32 and A32 Advanced SIMD and floating-point instruction.

Part G, The AArch32 System Level Architecture
Part G describes the AArch32 system level view of the architecture. It contains the following chapters:

Chapter G1 The AArch32 System Level Programmers’ Model
Read this for a description of the AArch32 system level view of the programmers’ model for execution in an Exception level that is using AArch32.

Chapter G2 AArch32 Self-hosted Debug
Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter G3 The AArch32 System Level Memory Model
Read this for a system level view of the general features of the memory system.

Chapter G4 The AArch32 Virtual Memory System Architecture
Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

Chapter G5 The Generic Timer in AArch32 state
Read this for a description of an implementation of the AArch32 view of the ARM Generic Timer.

Chapter G6 AArch32 System Register Descriptions
Read this for a description of each of the AArch32 system registers.

Part H, External Debug
Part H describes the architecture for external debug. It contains the following chapters:

Chapter H1 Introduction to External Debug
Read this for an introduction to external debug, and a definition of the scope of this part of the manual.

Chapter H2 Debug State
Read this for a description of debug state, which the PE might enter as the result of a Halting debug event.

Chapter H3 Halting Debug Events
Read this for a description of the external debug events referred to as Halting debug events.

Chapter H4 The Debug Communication Channel and Instruction Transfer Register
Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

Chapter H5 The Embedded Cross Trigger Interface
Read this for a description of the embedded cross-trigger interface.
Chapter H6 *Debug Reset and Powerdown Support*  
Read this for a description of reset and powerdown support in the Debug architecture.

Chapter H7 *The Sample-based Profiling Extension*  
Read this for a description of the Sample-based Profiling Extension that is an OPTIONAL extension to an ARMv8 implementation.

Chapter H8 *About the External Debug Registers*  
Read this for some additional information about the external debug registers.

Chapter H9 *External Debug Register Descriptions*  
Read this for a description of each external debug register.

**Part I, Memory-mapped Components of the ARMv8 Architecture**

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

Chapter I1 *System Level Implementation of the Generic Timer*  
Read this for a definition of a system level implementation of the Generic Timer.

Chapter I2 *Recommended Memory-mapped Interfaces to the Performance Monitors*  
Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

Chapter I3 *Memory-Mapped System Register Descriptions*  
Read this for a description of each memory-mapped system register.

**Part J, Appendixes**

This manual contains the following appendixes:

Appendix J1 *Architectural Constraints on UNPREDICTABLE behaviors*  
Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the ARMv8 architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Appendix J2 *Recommended External Debug Interface*  
Read this for a description of the recommended external debug interface.

**Note**  
This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix J3 *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*  
Read this for a description of ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers.

**Note**  
This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.
Appendix J4 Legacy Instruction Syntax for AArch32 Instruction Sets
Read this for information about the pre-UAL syntax of the AArch32 instruction sets, that can still be valid for the A32 instruction set.

Appendix J5 Example OS Save and Restore Sequences
Read this for software examples that perform the OS Save and Restore sequences for an ARMv8 debug implementation.

________ Note __________
Chapter H6 Debug Reset and Powerdown Support describes the OS Save and Restore mechanism.

Appendix J6 Recommended Upload and Download Processes for External Debug
Read this for information about implementing and using the ARM architecture.

________ Note __________
This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix J7 Barrier Litmus Tests
Read this for examples of the use of barrier instructions provided by the ARMv8 architecture.

________ Note __________
This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix J8 ARMv8 Pseudocode Library
Read this for the pseudocode definitions that are shared between AArch32 and AArch64.

Appendix J9 ARM Pseudocode Definition
Read this for definitions of the AArch32 pseudocode.

Appendix J10 Pseudocode Index
Read this for an index of the pseudocode.

Appendix J11 Registers Index
Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.
Conventions

The following sections describe conventions that this book can use:

- **Typographic conventions.**
- **Signals.**
- **Numbers.**
- **Pseudocode descriptions.**
- **Assembler syntax descriptions on page xxiv.**

**Typographic conventions**

The typographical conventions are:

**italic**
Introduces special terminology, and denotes citations.

**bold**
Denotes signal names, and is used for terms in descriptive lists, where appropriate.

**monospace**
Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

**SMALL CAPITALS**
Used in body text for a few terms that have specific technical meanings, and are defined in the Glossary.

**Colored text**
Indicates a link. This can be:

- A URL, for example http://infocenter.arm.com.
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, Pseudocode descriptions.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example Simple sequential execution or SCTLR.

**Signals**

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

**Signal level**
The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

**Lower-case n**
At the start or end of a signal name denotes an active-LOW signal.

**Numbers**

Numbers are normally written in decimal. Binary numbers are preceded by 0b, and hexadecimal numbers by 0x. In both cases, the prefix and the associated value are written in a monospace font, for example 0xFFFF0000. To improve readability, long numbers can be written with an underscore separator between every four characters, for example 0xFFFF_0000_0000_0000. Ignore any underscores when interpreting the value of a number.

**Pseudocode descriptions**

This manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in monospace font, and is described in Appendix J9 ARM Pseudocode Definition.
Assembler syntax descriptions

This manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a monospace font, and use the conventions described in Structure of the A64 assembler language on page C1-121, Appendix J9 ARM Pseudocode Definition, and Pseudocode operators and keywords on page J10-5780.
Additional reading

This section lists relevant publications from ARM and third parties.

See the Infocenter http://infocenter.arm.com, for access to ARM documentation.

ARM publications

- ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2 (ARM IHI 0031).
- ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).
- ARM® CoreSight™ v2.0 Architecture Specification (ARM IHI 0029).
- ARM® Procedure Call Standard for the ARM 64-bit Architecture (ARM IHI 0055).

• The page numbers to which your comments apply.
• A concise explanation of your comments.

ARM also welcomes general suggestions for additions and improvements.
Part A

ARMv8 Architecture Introduction and Overview
Chapter A1
Introduction to the ARMv8 Architecture

This chapter introduces the ARM architecture and contains the following sections:

• About the ARM architecture on page A1-32.
• Architecture profiles on page A1-34.
• ARMv8 architectural concepts on page A1-35.
• Supported data types on page A1-38.
• Cryptographic Extension on page A1-54.
• The ARM memory model on page A1-55.
A1.1 About the ARM architecture

The ARM architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a Processing Element, often abbreviated to PE. Implementations compliant with the ARM architecture must conform to the described behavior of the Processing Element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the ARM architecture must be the same as a simple sequential execution of the program on the processing element. This programmer-visible behavior does not include the execution time of the program.

The ARM Architecture Reference Manual also describes rules for software to use the Processing Element.

The ARM architecture includes definitions of:

- An associated debug architecture, see:
  - Chapter D2 AArch64 Self-hosted Debug.
  - Chapter G2 AArch32 Self-hosted Debug.
  - Part H of this manual, External Debug on page 4969.

- Associated trace architectures, that define trace macrocells that implementers can implement with the associated processor hardware. For more information see the Embedded Trace Macrocell Architecture Specification.

The ARM architecture is a Reduced Instruction Set Computer (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A load/store architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the Processing Element with memory, including caches, and includes a memory translation system. It also describes how multiple Processing Elements interact with each other and with other observers in a system.

This document defines the ARMv8-A architecture profile. See Architecture profiles on page A1-34 for more information.

The ARM architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the ARM architecture.

An important feature of the ARMv8 architecture is backwards compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases. The ARMv8 architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the ARM architecture.

Note

- The AArch32 Execution state is compatible with the ARMv7-A architecture profile, and enhances that profile to support some features included in the AArch64 Execution state.
- This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.
Both Execution states support SIMD and floating-point instructions:

- **AArch32 state provides:**
  - SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers.
  - Advanced SIMD instructions that operate on registers in the SIMD and floating-point register file.
  - Floating-point instructions that operate on registers in the SIMD and floating-point register file.

- **AArch64 state provides:**
  - Advanced SIMD instructions that operate on registers in the SIMD and floating-point register file.
  - Floating-point instructions that operate on registers in the SIMD and floating-point register file.

---

**Note**

See *Conventions on page xxiii* for information about conventions used in this manual, including the use of SMALL CAPITALS for particular terms that have ARM-specific meanings that are defined in the *Glossary*. 
A1.2 Architecture profiles

The ARM architecture has evolved significantly since its introduction, and ARM continues to develop it. Eight major versions of the architecture have been defined to date, denoted by the version numbers 1 to 8. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

**AArch64**
Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

**AArch32**
Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

Note

The **Base instruction set** comprises the supported instructions other than the Advanced SIMD and floating-point instructions.

ARM defines three architecture profiles:

**A**
Application profile, described in this manual:
- Supports a Virtual Memory System Architecture (VMSA) based on a Memory Management Unit (MMU).

Note

An ARMv8-A implementation can be called an AArchv8-A implementation.

- Supports the A64, A32, and T32 instruction sets.

**R**
Real-time profile:
- Supports a Protected Memory System Architecture (PMSA) based on a Memory Protection Unit (MPU).
- Supports the A32 and T32 instruction sets.

**M**
Microcontroller profile:
- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the R-profile PMSA.
- Supports a variant of the T32 instruction set.

Note

This Architecture Reference Manual describes only the ARMv8-A profile.

For information about the R and M architecture profiles, and earlier ARM architecture versions see:

A1.2.1 Debug architecture version

The ARM Debug architecture is fully integrated with the architecture, and does not have a separate version number.
A1.3 ARMv8 architectural concepts

ARMv8 introduces major changes to the ARM architecture, while maintaining a high level of consistency with previous versions of the architecture. The ARMv8 Architecture Reference Manual includes significant changes in the terminology used to describe the architecture, and this section introduces both the ARMv8 architectural concepts and the associated terminology.

The following subsections describe key ARMv8 architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- **Execution state.**
- **The ARM instruction sets** on page A1-36.
- **System registers** on page A1-36.
- **ARMv8 Debug** on page A1-37.

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The exception model.
  - The Virtual Memory System Architecture (VMSA).
  - The programmers’ model.

The Execution states are:

**AArch64**

The 64-bit Execution state. This Execution state:

- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit program counter (PC), stack pointers (SPs), and exception link registers (ELRs).
- Provides 32 128-bit registers for SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see The ARM instruction sets on page A1-36.
- Defines the ARMv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an execution privilege hierarchy, see Exception levels on page D1-1490.
- Provides support for 64-bit virtual addressing. For more information, including the limits on address ranges, see Chapter D4 The AArch64 Virtual Memory System Architecture.
- Defines a number of Process state (PSTATE) elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each system register using a suffix that indicates the lowest Exception level at which the register can be accessed.

**AArch32**

The 32-bit Execution state. This Execution state:

- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and link register (LR). The LR is used as both an ELR and a procedure link register. Some of these registers have multiple banked instances for use in different PE modes.
- Provides a single ELR, for exception returns from Hyp mode.
- Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides two instruction sets, A32 and T32. For more information, see The ARM instruction sets on page A1-36.
- Supports the ARMv7-A exception model, based on PE modes, and maps this onto the ARMv8 Exception model, that is based on the Exception levels.
- Provides support for 32-bit virtual addressing.
• Defines a number of Process state (PSTATE) elements that hold PE state. The A32 and T32 instruction sets include instructions that operate directly on various PSTATE elements, and instructions that access PSTATE by using the Application Program Status Register (APSR) or the Current Program Status Register (CPSR).

Later subsections give more information about the different properties of the Execution states.

Transitioning between the AArch64 and AArch32 Execution states is known as interprocessing. The PE can move between Execution states only on a change of Exception level, and subject to the rules given in Interprocessing on page D1-1604. This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2 The ARM instruction sets

In ARMv8 the possible instruction sets depend on the Execution state:

AArch64  
AArch64 state supports only a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings. For information on the A64 instruction set, see Chapter C3 A64 Instruction Set Overview.

AArch32  
AArch32 state supports the following instruction sets:

A32  
This is a fixed-length instruction set that uses 32-bit instruction encodings.

T32  
This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb instruction sets. ARMv8 extends each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the A32 and T32 instruction sets, see Chapter F1 The AArch32 Instruction Sets Overview.

The ARMv8 instruction sets support SIMD and scalar floating-point instructions. See Floating-point and Advanced SIMD support on page A1-48.

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

• <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see Exception levels on page D1-1490.

The System registers comprise:

• General system control registers.
• Debug registers.
• Generic Timer registers.
• Optionally, Performance Monitor registers.
• Optionally, Trace registers.
• Optionally, Generic Interrupt Controller (GIC) CPU interface registers.

The Embedded Trace Macrocell Architecture Specification, ETMv4 defines the Trace registers. This ARMv8 reference manual describes all the other System registers.
For information about the AArch64 System registers, see Chapter D7 AArch64 System Register Descriptions.
For information about the AArch32 System registers, see Chapter G6 AArch32 System Register Descriptions.

The ARM Generic Interrupt Controller CPU interface

From version 3 of the ARM Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a system register interface to the GIC CPU interface. The System register descriptions in this ARMv8 manual include these registers, see Generic Interrupt Controller CPU interface System registers on page D7-2293.

Note
The programmers’ model for earlier versions of the GIC architecture is wholly memory-mapped.

For more information about the ARM Generic Interrupt Controller, see the appropriate ARM Generic Interrupt Controller Architecture Specification.

A1.3.4 ARMv8 Debug

ARMv8 supports the following:

Self-hosted debug
In this model, the PE generates debug exceptions. Debug exceptions are part of the ARMv8 Exception model.

External debug
In this model, debug events cause the PE to enter Debug state. In Debug state the PE is controlled by an external debugger.

All ARMv8 implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:
• In AArch64 state, see Chapter D2 AArch64 Self-hosted Debug.
• In AArch32 state, see Chapter G2 AArch32 Self-hosted Debug.

For more information about external debug, see Part H External Debug.
A1.4 Supported data types

The ARMv8 architecture supports the following integer data types:

- **Byte** 8 bits.
- **Halfword** 16 bits.
- **Word** 32 bits.
- **Doubleword** 64 bits.
- **Quadword** 128 bits.

The architecture also supports the following floating-point data types:

- Double-precision, see *Double-precision floating-point format* on page A1-45 for details.

It also supports:

- Vectors, where a register holds multiple elements, each of the same data type. See *Vector formats* on page A1-39 for details.

The ARMv8 architecture provides two register files:

- A general-purpose register file.
- A SIMD and floating-point register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- A general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers or as 32-bit registers, using only the bottom 32 bits.
- A SIMD and floating-point register file contains 128-bit registers:
  - The quadword integer data types only apply to the SIMD and floating-point register file.
  - The floating-point data types only apply to the SIMD and floating-point register file.
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see *Instruction Mnemonics* on page C1-121.

For more information on the register files in AArch64, see *Registers in AArch64 Execution state* on page B1-61.

In AArch32 state:

- A general-purpose register file contains 32-bit registers:
  - Two 32-bit registers can support a doubleword.
  - Vector formatting is supported, see *Figure A1-4* on page A1-42.
- A SIMD and floating-point register file contains 64-bit registers:
  - AArch32 state does not support quadword integer or floating-point data types.

**Note**

Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2384.
A1.4.1 Vector formats

In an implementation that includes the SIMD instructions that operate on the SIMD and floating-point register file, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector.

Vector formats in AArch64 state

In AArch64 state, the SIMD and floating-point registers can be referred to as Vn, where n is a value from 0 to 31.

The SIMD and floating-point registers support three data formats for loads, stores and data processing operations:

• A single, scalar, element in the least significant bits of the register.
• A 64-bit vector of byte, halfword, or word elements.
• A 128-bit vector of byte, halfword, word or doubleword elements.

The element sizes are defined in Table A1-1 with the vector format described as:

• For a 128-bit vector: Vn{.2D, .4S, .8H, .16B}.
• For a 64-bit vector: Vn{.1D, .2S, .4H, .8B}.

<table>
<thead>
<tr>

<td>32 bits</td>
</tr>
<tr>
<td>D</td>
<td>64 bits</td>
</tr>
</tbody>
</table>

Figure A1-1 on page A1-40 shows the SIMD vectors in AArch64 state.
A1 Introduction to the ARMv8 Architecture
A1.4 Supported data types

Figure A1-1 SIMD vectors in AArch64 state

Vector formats in AArch32 state

Table A1-2 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A1-2 Advanced SIMD data types in AArch32

<table>
<thead>
<tr>
<th>Data type specifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.&lt;size&gt;</td>
<td>Any element of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.F&lt;size&gt;</td>
<td>Floating-point number of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.I&lt;size&gt;</td>
<td>Signed or unsigned integer of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.P&lt;size&gt;</td>
<td>Polynomial over {0,1} of degree less than &lt;size&gt;</td>
</tr>
<tr>
<td>.S&lt;size&gt;</td>
<td>Signed integer of &lt;size&gt; bits</td>
</tr>
<tr>
<td>.U&lt;size&gt;</td>
<td>Unsigned integer of &lt;size&gt; bits</td>
</tr>
</tbody>
</table>

Polynomial arithmetic over \{0, 1\} on page A1-47 describes the polynomial data type.

The .F16 data type is the half-precision data type selected by the FPSCR.AHP bit.

The .F32 data type is the ARM standard single-precision floating-point data type, see Single-precision floating-point format on page A1-44.

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-2 on page A1-41 shows the hierarchy of the Advanced SIMD data types.
For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

Figure A1-3 on page A1-42 shows the Advanced SIMD vectors in AArch32 state.

Note

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.
The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 shows these formats, that means that a general-purpose register can be treated as either two halfwords or four bytes.

### A1.4.2 Half-precision floating-point formats

ARMv8 supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.
- Alternative half-precision.

**Note**

Half-precision floating-point formats can only be converted to and from other floating-point formats. They cannot be used in any other data processing operations. This applies to both AArch32 state and AArch64 state.
The description of IEEE half-precision includes ARM-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:

```
| 15 14 | 10 9 | 0 |
| S exponent | fraction |
```

The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

### 0 < exponent < 0x1F

The value is a normalized number and is equal to:

\[ (-1)^S \times 2^{(\text{exponent}-15)} \times (1.\text{fraction}) \]

The minimum positive normalized number is \(2^{-14}\), or approximately \(6.104 \times 10^{-5}\).

The maximum positive normalized number is \((2 - 2^{-10})\times2^{15}\), or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == 0x1F.

#### exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

- **fraction == 0**
  - The value is a zero. There are two distinct zeros:
    - +0 when S==0
    - −0 when S==1.

- **fraction != 0**
  - The value is a denormalized number and is equal to:
    \[ (-1)^S \times 2^{-14} \times (0.\text{fraction}) \]
  - The minimum positive denormalized number is \(2^{-24}\), or approximately \(5.960 \times 10^{-8}\).

### exponent == 0x1F

The value depends on which half-precision format is being used:

#### IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

- **fraction == 0**
  - The value is an infinity. There are two distinct infinities:
    - +infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.
    - -infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

- **fraction != 0**
  - The value is a NaN, and is either a quiet NaN or a signaling NaN.
  - The two types of NaN are distinguished by their most significant fraction bit, bit[9]:
    - bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.
    - bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.
Alternative half-precision

The value is a normalized number and is equal to:

\[-1^S \times 2^{16} \times (1.\text{fraction})\]

The maximum positive normalized number is \((2^{-2^{10}}) \times 2^{16}\) or 131008.

A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes ARM-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

```
31 30  |  23  22  |    |    |  0
S  exponent  fraction
```

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

**0 < exponent < 0xFF**

The value is a normalized number and is equal to:

\[-1^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})\]

The minimum positive normalized number is \(2^{-126}\), or approximately \(1.175 \times 10^{-38}\).

The maximum positive normalized number is \((2 - 2^{-23}) \times 2^{127}\), or approximately \(3.403 \times 10^{38}\).

**exponent == 0**

The value is either a zero or a denormalized number, depending on the fraction bits:

**fraction == 0**

The value is a zero. There are two distinct zeros:

+0 When S==0.

–0 When S==1.

These usually behave identically. In particular, the result is equal if +0 and –0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

**fraction != 0**

The value is a denormalized number and is equal to:

\[-1^S \times 2^{-126} \times (0.\text{fraction})\]

The minimum positive denormalized number is \(2^{-149}\), or approximately \(1.401 \times 10^{-45}\).

Denormalized numbers are always flushed to zero in AArch32 Advanced SIMD processing. They are optionally flushed to zero in floating-point processing and AArch64 SIMD. For details see Flush-to-zero on page A1-51.

**exponent == 0xFF**

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

**fraction == 0**

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.
fraction != 0
The value is a NaN, and is either a quiet NaN or a signaling NaN.
The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0
The NaN is a signaling NaN. The sign bit can take any value, and the
remaining fraction bits can take any value except all zeros.

bit[22] == 1
The NaN is a quiet NaN. The sign bit and remaining fraction bits can take
any value.

For details of the default NaN see NaN handling and the Default NaN on page A1-52.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point
comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares
as unordered with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point
is supported by both floating-point and SIMD instructions in AArch64 state, and only by floating-point instructions
in AArch32 state.

This description includes implementation-specific details that are left open by the standard. It is only intended as an
introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities,
NaNs and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:

```
<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
<th>52</th>
<th>51</th>
<th>32</th>
<th>31</th>
<th>...</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>exponent</td>
<td>fraction</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Double-precision values represent numbers, infinities and NaNs in a similar way to single-precision values, with
the interpretation of the format depending on the value of the exponent:

0 < exponent < 0x7FF
The value is a normalized number and is equal to:

\[
(-1)^S \times 2^{(exponent-1023)} \times (1.fraction)
\]

The minimum positive normalized number is 2^{-1022}, or approximately 2.225 \times 10^{-308}.
The maximum positive normalized number is (2 - 2^{-52}) \times 2^{1023}, or approximately 1.798 \times 10^{308}.

exponent == 0
The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0
The value is a zero. There are two distinct zeros that behave in the same way as the two
single-precision zeros:

+0 when S==0
–0 when S==1.

fraction != 0
The value is a denormalized number and is equal to:

\[
(-1)^S \times 2^{-1022} \times (0.fraction)
\]

The minimum positive denormalized number is 2^{-1074}, or approximately 4.941 \times 10^{-324}. 

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details see *Flush-to-zero* on page A1-51.

\[
\text{exponent} = 0x7FF
\]

The value is either an infinity or a NaN, depending on the fraction bits:

\[
\text{fraction} == 0
\]

The value is an infinity. As for single-precision, there are two infinities:

+\*infinity\* When S==0.
-\*infinity\* When S==1.

\[
\text{fraction} != 0
\]

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

\[
\text{bit}[51] == 0
\]

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

\[
\text{bit}[51] == 1
\]

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN* see *NaN handling and the Default NaN* on page A1-52.

---

**Note**

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as unordered with everything, including itself.

---

### A1.4.5 Fixed-point format

Fixed-point formats are used only for conversions between floating-point and fixed-point values. They apply to general-purpose registers.

Fixed-point values can be signed or unsigned, and can be 16-bit or 32-bit. Conversion instructions take an argument that specifies the number of fraction bits in the fixed-point number. That is, it specifies the position of the binary point.

### A1.4.6 Conversion between floating-point and fixed-point values

ARMv8 supports the conversion of a scalar floating-point to or from a signed or unsigned fixed-point value in a general-purpose register.

The instruction argument \#fbits indicates that the general-purpose register holds a fixed-point number with \#fbits bits after the binary point, where \#fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register.

More specifically:

- For a 64-bit register Xₜ:
  - The integer part is \(Xₜ[63:\#fbits]\).
  - The fractional part is \(Xₜ[\#fbits-1:0]\).

- For a 32-bit register Wₜ or Rₜ:
  - The integer part is \(Wₜ[31:\#fbits]\) or \(Rₜ[31:\#fbits]\).
  - The fractional part is \(Wₜ[\#fbits-1:0]\) or \(Rₜ[\#fbits-1:0]\).
These instructions might generate the following exceptions:

**Invalid Operation** When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

**Inexact** When the numeric result differs from the input.

**Input Denormal** When flush-to-zero mode is enabled and the denormal input is replaced by a zero.

--- **Note** ---

An out of range fixed-point result is saturated to the destination size.

### A1.4.7 Polynomial arithmetic over \{0, 1\}

Some SIMD instructions that operate on SIMD and floating-point registers can operate on polynomials over \{0, 1\}, see [Supported data types](#) on page A1-38. The polynomial data type represents a polynomial in x of the form \(b_{n-1}x^{n-1} + \ldots + b_1x + b_0\) where \(b_k\) is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- \(0 + 0 = 1 + 1 = 0\)
- \(0 + 1 = 1 + 0 = 1\)
- \(0 \times 0 = 0 \times 1 = 1 \times 0 = 0\)
- \(1 \times 1 = 1\).

That is:

- Adding two polynomials over \{0, 1\} is the same as a bitwise exclusive OR.
- Multiplying two polynomials over \{0, 1\} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32 and T32 provide instructions for performing polynomial multiplication of 8-bit values.

- For AArch32, see [VMUL (integer and polynomial)](#) on page F8-3565 and [VMULL (integer and polynomial)](#) on page F8-3571.
- For AArch64, see [PMUL](#) on page C7-1151 and [PMULL, PMULL2](#) on page C7-1153.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See [PMULL, PMULL2](#) on page C7-1153.

**Pseudocode description of polynomial multiplication**

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function:

```plaintext
// PolynomialMult()
// ================
bits(M+N) PolynomialMult(bits(M) op1, bits(N) op2)
result = Zeros(M+N);
extended_op2 = ZeroExtend(op2, M+N);
for i=0 to M-1
    if op1[i] == '1' then
        result = result EOR LSL(extended_op2, i);
return result;
```
A1.5 Floating-point and Advanced SIMD support

Note

In AArch32 state, the SIMD instructions that operate on SIMD and floating-point registers are always described as the Advanced SIMD instructions, to distinguish them from the SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers. The A64 instruction set does not provide any SIMD instructions that operate on the general-purpose registers, and therefore some AArch64 state descriptions use SIMD as a synonym for Advanced SIMD. Unless the context clearly indicates otherwise, this section describes the support for SIMD instructions that operate on SIMD and floating-point registers.

ARMv8 can support the following levels of support for floating-point and Advanced SIMD instructions:

- Full floating-point and SIMD support without exception trapping.
- Full floating-point and SIMD support with exception trapping.
- No floating-point or SIMD support. This option is licensed only for implementations targeting specialised markets.

Note

All systems that support standard operating systems with rich application environments provide hardware support for floating-point and Advanced SIMD. It is a requirement of the ARM Procedure Call Standard for AArch64, see Procedure Call Standard for the ARM 64-bit Architecture.

ARMv8 supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage only, by supporting conversions between single-precision and half-precision data types and double-precision and half-precision data types.

The SIMD instructions provide packed Single Instruction Multiple Data (SIMD) and single-element scalar operations, and support:

- Single-precision and double-precision arithmetic in AArch64 state.
- Single-precision arithmetic only in AArch32 state.

Floating-point support in AArch64 state SIMD is IEEE 754-2008 compliant with:

- Configurable rounding modes.
- Configurable Default NaN behavior.
- Configurable Flush-to-zero behavior.

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from ARMv7. A32 and T32 Advanced SIMD floating-point always uses ARM standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see Flush-to-zero on page A1-51.
- Only default NaNs are supported, see NaN handling and the Default NaN on page A1-52.
- The Round to Nearest rounding mode is used.
- Untrapped floating-point exception handling is used for all floating-point exceptions.

ARMv8 introduces new instructions for AArch32 state:

- Floating-point selection, see VSELEQ, VSELGE, VSELGT, VSELVS on page F8-3721.
- Floating-point maximum and minimum numbers, see FMAXN on page F8-3503 and FMINNM on page F8-3510.
- Floating-point integer conversions with directed rounding modes, see:
  - VCVTA (Advanced SIMD) on page F8-3405 and VCVTA (floating-point) on page F8-3407.
  - VCVTM (Advanced SIMD) on page F8-3412 and VCVTM (floating-point) on page F8-3414.
  - VCVTN (Advanced SIMD) on page F8-3416 and VCVTN (floating-point) on page F8-3418.
  - VCVTP (Advanced SIMD) on page F8-3420 and VCVTP (floating-point) on page F8-3422.
Floating-point round to integral floating-point, see:
- VRINTA (Advanced SIMD) on page F8-3677 and VRINTA (floating-point) on page F8-3679.
- VRINTM (Advanced SIMD) on page F8-3681 and VRINTM (floating-point) on page F8-3683.
- VRINTN (Advanced SIMD) on page F8-3685 and VRINTN (floating-point) on page F8-3687.
- VRINTP (Advanced SIMD) on page F8-3689 and VRINTP (floating-point) on page F8-3691.
- VRINTR on page F8-3693.
- VRINTX (Advanced SIMD) on page F8-3695 and VRINTX (floating-point) on page F8-3697.
- VRINTZ (Advanced SIMD) on page F8-3699 and VRINTZ (floating-point) on page F8-3701.

Floating-point conversions between half-precision and double-precision, see VCVTB on page F8-3409 and VCVTT on page F8-3427.

If floating-point exception trapping is supported, floating-point exceptions, such as overflow or division by zero, can be handled without trapping. This applies to both floating-point and SIMD operations. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. For more information about floating-point exceptions, see Supported data types on page A1-38.

In AArch64 state, the following registers control floating-point operation and return floating-point status information:

- The Floating-Point Control Register, FPCR, controls:
  - The half-precision format where applicable, FPCR.AHP bit.
  - Default NaN behavior, FPCR.DN bit.
  - Flush to zero behavior, FPCR.FZ bit.
  - Rounding mode support, FPCR.Rmode field.
  - Len and Stride fields associated with AArch32 execution, and only supported for a context save and restore in AArch64. These fields are obsolete in ARMv8 and can be implemented as RAZ/WI. If they are implemented as R/W and are programmed to a nonzero value, they make some AArch32 floating-point instructions UNDEFINED.
  - Floating-point exception trap controls, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits, see Floating-point exception traps on page D1-1549. In an implementation that does not support trapping of floating-point exceptions these bits are RES0.

- The Floating-Point Status Register, FPSR, provides:
  - Cumulative floating-point exceptions flags, FPSR.{IDC, IXC, UFC, OFC, DZC, IOC and QC}.
  - The AArch32 floating-point comparison flags {N,Z,C,V}. These bits are RES0 if AArch32 floating-point is not supported.

  **Note**

  In AArch64, the process state flags, PSTATE.{N,Z,C,V} are used for all data processing compares and any associated conditional execution.

AArch32 state provides a single Floating-Point Status and Control Register, FPSCR, combining the FPCR and FPSR fields.

For system level information about the SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-3914.

### A1.5.1 Instruction support

The floating-point and SIMD support includes the following types of instructions:

- Load and store for single elements and vectors of multiple elements.
A1.5 Floating-point and Advanced SIMD support

Note

Single elements are also referred to as scalar elements.

• Data processing on single and multiple elements for both integer and floating-point data types.

• Floating-point conversion:
  — Half-precision, single-precision, and double-precision conversions.
  — Single-precision, double-precision, and fixed point integer conversions.
  — Single-precision, double-precision, and integer conversions.

• Floating-point rounding.

For more information on the floating-point and SIMD instructions in AArch64 state, see Chapter C3 A64 Instruction Set Overview.

For more information on the floating-point and Advanced SIMD instructions in AArch32 state, see Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings.

A1.5.2 Floating-point standards, and terminology

The ARM includes support for all the required features of ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as IEEE 754-2008. However, some terms in this manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

• ARM floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.

• References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-3 shows how the terminology in this manual differs from that used in IEEE 754-2008.

Table A1-3 Floating-point terminology

</table>

a. Normalized number is used in preference to normal number, because of the other specific uses of normal in this manual.

A1.5.3 ARM standard floating-point input and output values

ARMv8 provides full IEEE 754 floating-point arithmetic support. In AArch32, floating-point operations performed using Advanced SIMD instructions are limited to ARM standard floating-point operation, regardless of the selected rounding mode in the FPSCR. Unlike AArch32, AArch64 SIMD floating point arithmetic is performed using the rounding mode selected by the FPCR.
ARM standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see **Flush-to-zero**.
- NaNs.
- Infinities.

ARM standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

ARM standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see **Flush-to-zero**.
- NaNs produced in floating-point operations are always the default NaN, see **NaN handling and the Default NaN** on page A1-52.
- Infinities.

### A1.5.4 Flush-to-zero

The performance of floating-point processing can be reduced when doing calculations involving denormalized numbers and Underflow exceptions. In many algorithms, this performance can be recovered, without significantly affecting the accuracy of the final result, by replacing the denormalized operands and intermediate results with zeros. To permit this optimization, ARM floating-point implementations have a special processing mode called **Flush-to-zero** mode. AArch32 Advanced SIMD floating-point instructions always use Flush-to-zero mode.

Behavior in Flush-to-zero mode differs from normal IEEE 754 arithmetic in the following ways:

- All inputs to floating-point operations that are double-precision denormalized numbers or single-precision denormalized numbers are treated as though they were zero. This causes an Input Denormal exception, but does not cause an Inexact exception. The Input Denormal exception occurs only in Flush-to-zero mode.
  
  In AArch32, the FPSCR contains a cumulative exception bit FPSCR.IDC and optional trap enable bit FPSCR.IDE corresponding to Input Denormal exception.
  
  In AArch64 the FPSR contains a cumulative exception bit FPSR.IDC and optional trap enable bit FPCR.IDE corresponding to the Input Denormal exception.

  The occurrence of all exceptions except Input Denormal is determined using the input values after flush-to-zero processing has occurred.

- The result of a floating-point operation is flushed to zero if the result of the operation before rounding satisfies the condition:

\[
0 < \text{Abs}(\text{result}) < \text{MinNorm}, \text{where:}
\]

  - MinNorm is \(2^{-126}\) for single-precision
  - MinNorm is \(2^{-1022}\) for double-precision.

  This causes the FPSR.UFC bit to be set to 1, and prevents any Inexact exception from occurring for the operation.

  Underflow exceptions occur only when a result is flushed to zero.

In all implementations Underflow exceptions that occur in Flush-to-zero mode are always treated as untrapped, even when the Underflow trap enable bit, FPCR.UFE, is set to 1.
• An Inexact exception does not occur if the result is flushed to zero, even though the final result of zero is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

When an input or a result is flushed to zero the value of the sign bit of the zero is preserved. That is, the sign bit of the zero matches the sign bit of the input or result that is being flushed to zero.

Flush-to-zero mode has no effect on half-precision numbers that are inputs to floating-point operations, or results from floating-point operations.

Note
Flush-to-zero mode is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Flush-to-zero mode must be used with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application dependent:

• On many algorithms, it has no noticeable effect, because the algorithm does not normally use denormalized numbers.

• On other algorithms, it can cause exceptions to occur or seriously reduce the accuracy of the results of the algorithm.

A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard specifies that:

• An operation that produces an Invalid Operation floating-point exception generates a quiet NaN as its result if that exception is untrapped.

• An operation involving a quiet NaN operand, but not a signaling NaN operand, returns an input NaN as its result.

The floating-point processing behavior when Default NaN mode is disabled adheres to this, with the following additions:

• If an untrapped Invalid Operation floating-point exception is produced, the quiet NaN result is derived from:
  — The first signaling NaN operand, if the exception was produced because at least one of the operands is a signaling NaN.
  — Otherwise, the default NaN.

• If an untrapped Invalid Operation floating-point exception is not produced, but at least one of the operands is a quiet NaN, the result is derived from the first quiet NaN operand.

Depending on the operation, the exact value of a derived quiet NaN result may differ in both sign and number of fraction bits from its source. For a quiet NaN result derived from signaling NaN operand, the most-significant fraction bit is set to 1.

Note
• In these descriptions, first operand relates to the left-to-right ordering of the arguments to the pseudocode function that describes the operation.

• The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

The floating-point and SIMD processing behavior when Default NaN mode is enabled is that the Default NaN is the result of all floating-point operations that either:

• Generate untrapped Invalid Operation floating-point exceptions.

• Have one or more quiet NaN inputs, but no signaling NaN inputs.

Table A1-4 on page A1-53 shows the format of the default NaN for ARM floating-point operations.

Default NaN mode is selected for the floating-point processing by setting the FPCR.DN bit to 1.
Other aspects of the functionality of the Invalid Operation exception are not affected by Default NaN mode. These are that:

- If untrapped, it causes the FPSR.IOC bit be set to 1.
- If trapped, it causes a user trap handler to be invoked.

A1.6 Cryptographic Extension

The presence of this Extension in an implementation is subject to export license controls. The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file. It provides instructions for the acceleration of encryption and decryption to support the following:

- AES
- SHA1
- SHA2-256

Large polynomial multiplies are included as part of the Cryptographic Extension, see PMULL, PMULL2 on page C7-1153.
A1.7 The ARM memory model

The ARM memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating virtual addresses provided by executing instructions into physical addresses.
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.

Virtual address (VA) support depends on the Execution state, as follows:

**AArch64 state**

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

**AArch32 state**

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported physical address space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the Virtual Memory System Architecture (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported physical address space.

For more information, see:

**For execution in AArch64 state**

- Chapter B2 The AArch64 Application Level Memory Model.
- Chapter D3 The AArch64 System Level Memory Model.
- Chapter D4 The AArch64 Virtual Memory System Architecture.

**For execution in AArch32 state**

- Chapter G3 The AArch32 System Level Memory Model.
- Chapter G4 The AArch32 Virtual Memory System Architecture.
Part B

The AArch64 Application Level Architecture
Chapter B1
The AArch64 Application Level Programmers’ Model

This chapter gives an application level view of the ARM programmers’ model. It contains the following sections:

• About the Application level programmers` model on page B1-60.
• Registers in AArch64 Execution state on page B1-61.
• Software control features and EL0 on page B1-67.
B1.1 About the Application level programmers’ model

This chapter contains the programmers’ model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different Exception levels that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers’ model is the programmers’ model for software executing at EL0. For more information see Exception levels on page D1-1490.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to Chapter D1 The AArch64 System Level Programmers’ Model.
B1.2 Registers in AArch64 Execution state

This section describes the registers and process state visible at EL0 when executing in the AArch64 state. It includes the following:

- Registers in AArch64 state
- Process state, PSTATE on page B1-64
- System registers on page B1-65

B1.2.1 Registers in AArch64 state

In the AArch64 application level view, an ARM Processing element has:

- **R0-R30**
  31 general-purpose registers, R0 to R30. Each register can be accessed as:
  - A 64-bit general-purpose register named X0 to X30.
  - A 32-bit general-purpose register named W0 to W30.

  See the register name mapping in Figure B1-1.

- **SP**
  A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack-pointer can be accessed via the register name WSP.

  The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

- **PC**
  A 64-bit Program Counter holding the address of the current instruction.

  Software cannot write directly to the PC. It can only be updated on a branch, exception entry or exception return.

- **V0-V31**
  32 SIMD and floating-point registers, V0 to V31. Each register can be accessed as:
  - A 128-bit register named Q0 to Q31.
  - A 64-bit register named D0 to D31.
  - A 32-bit register named S0 to S31.
  - A 16-bit register named H0 to H31.
  - An 8-bit register named B0 to B31.
• A 128-bit vector of elements.
• A 64-bit vector of elements.

Where the number of bits described by a register name does not occupy an entire SIMD and floating-point register, it refers to the least significant bits. See Figure B1-2.

For more information about data types and vector formats, see Supported data types on page A1-38.

**FPCR, FPSR** Two SIMD and floating-point control and status registers, FPCR and FPSR.

See Registers for instruction processing and exception handling on page D1-1499 for more information on the registers.

**Pseudocode description of registers in AArch64 state**

In the pseudocode functions that access registers:
• The assignment form is used for register writes.
• The non-assignment for register reads.

The uses of the X[] function are:
• Reading or writing X0-X30, using n to index the required register.
• Reading the zero register ZR, accessed as X[31].

---

**Note**

The pseudocode use of X[31] to represent the zero register does not indicate that hardware must implement this register.

---

```c
// X[] - assignment form
// ===============
// Write to general-purpose register from either a 32-bit or a 64-bit value.

int X[integer n] = bits(width) value
assert n >= 0 && n <= 31;
assert width IN {32,64};
if n != 31 then
    _R[n] = ZeroExtend(value);
return;

// X[] - non-assignment form
// ===============
// Read from general-purpose register with implicit slice of 8, 16, 32 or 64 bits.

bits(width) X[integer n]
assert n >= 0 && n <= 31;
assert width IN {8,16,32,64};
if n != 31 then
    return _R[n]<width-1:0>;
e else
```

---

**Figure B1-2 SIMD and floating-point register naming**

127 64 63 32 16 8 7 0

Vn Hn
Bn Sn
Dn Qn
return Zeros(width);

The R[] function provides a view of the physical array of the physical general-purpose registers.

array bits(64) R[0..30];

The SP[] function is used to read or write the current SP. This function has prototypes:

SP[] = bits(width) value;

bits(width) SP[];

The PC[] function is used to read the PC. This function has prototype:

bits(64) PC[];

The V[] function provides a view of the physical array of the physical SIMD and floating-point registers.

array bits(128) V[0..31];

The V[] function is used to read or write V0-V31, using n to index the required register.

// V[] - assignment form
// =====================
// Write to SIMD&FP register with implicit extension from // 8, 16, 32, 64 or 128 bits.

V[integer n] = bits(width) value
assert n >= 0 && n <= 31;
assert width IN {8,16,32,64,128};
_V[n] = ZeroExtend(value);
return;

// V[] - non-assignment form
// =========================
// Read from SIMD&FP register with implicit slice of 8, 16 // 32, 64 or 128 bits.

bits(width) V[integer n]
assert n >= 0 && n <= 31;
assert width IN {8,16,32,64,128};
return _V[n]<width-1:0>;

The Vpart[] function is used to read or write the lower or upper half of V0-V31, using n to index the required register, and part to indicate the required half.

// Vpart[] - non-assignment form
// =============================
// Reads a 128-bit SIMD&FP register in up to two parts: // part 0 returns the bottom 8, 16, 32 or 64 bits of the register; // part 1 returns only the top 64 bits of the register.

bits(width) Vpart[integer n, integer part]
assert n >= 0 && n <= 31;
assert part IN {0, 1};
if part == 0 then
assert width IN {8,16,32,64};
 return _V[n]<width-1:0>;
else
test width == 64;
return _V[n]<127:64>;

// Vpart[] - assignment form
// =========================
// Write a 128-bit SIMD&FP register in up to two parts: // part 0 zero extends a 8, 16, 32, or 64-bit value to fill the whole register; // part 1 inserts a 64-bit value into the top 64 bits of the register.

Vpart[integer n, integer part] = bits(width) value
assert n >= 0 && n <= 31;
assert part IN {0, 1};
if part == 0 then
    assert width IN {8,16,32,64};
    _V[n] = ZeroExtend(value);
else
    assert width == 64;
    _V[n][127:64] = value[63:0];

B1.2.2 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

The following PSTATE information is accessible at EL0:

The condition flags

Flag-setting instructions set these. They are:

N Negative condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
- 1 if the result is negative.
- 0 if the result is positive or zero.

Z Zero condition flag. Set to:
- 1 if the result of the instruction is zero.
- 0 otherwise.
A result of zero often indicates an equal result from a comparison.

C Carry condition flag. Set to:
- 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
- 0 otherwise.

V Overflow condition flag. Set to:
- 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
- 0 otherwise.

Conditional instructions test the N, Z, C and V condition flags, combining them with the condition code for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see Condition flags and related instructions on page C6-402.

The exception masking bits

D Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.

A SError interrupt mask bit.

I IRQ interrupt mask bit.

F FIQ interrupt mask bit.

For each bit, the values are:
0 Exception not masked
1 Exception masked

Access at EL0 using AArch64 state depends on SCTLR_EL1.VMA. See Traps to EL1 of EL0 accesses to the PSTATE, [D, A, I, F] interrupt masks on page D1-1561.

See Process state, PSTATE on page D1-1506 for the system level view of PSTATE.
Accessing PSTATE fields at EL0

At EL0 using AArch64 state, PSTATE fields can be accessed using the Special-purpose registers. The Special-purpose registers can be directly read using the MRS instruction and directly written using the MSR (register) instructions. Table B1-1 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state when the PE is at EL0 using AArch64. All other PSTATE fields do not have direct read and write access at EL0.

Software can also use the MSR (immediate) instruction to directly write to PSTATE.{D, A, I, F}. Table B1-2 shows the MSR (immediate) operands that can directly write to PSTATE.{D, A, I, F} when the PE is at EL0 using AArch64 state.

Table B1-1 Accessing PSTATE fields at EL0 using MRS and MSR (register)

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>DAIF</td>
<td>D, A, I, F</td>
</tr>
</tbody>
</table>

However, access to the PSTATE.{D, A, I, F} fields at EL0 using AArch64 state depends on SCTLR_EL1.UMA. *Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks* on page D1-1561.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

B1.2.3 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some system registers can be configured to allow access from software executing at EL0. Any access from EL0 to a system register with the access right disabled causes the instruction to behave as an UNDEFINED instruction. The registers that can be accessed from EL0 are:

**Cache ID registers**

The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.

**Debug registers**

A debug communications channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0 and DBGDTRTX_EL0 registers.

**Performance Monitors registers**

See *Performance Monitors support* on page B1-66.

**Thread ID registers**

The TPIDR_EL0 and TPIDRRO_EL0 registers are two thread ID registers with different access rights.

**Timer registers**

In ARMv8 the following operations are performed:

- Read access to the system counter clock frequency using CNTFRQ_EL0.
- Physical and virtual timer count registers, CNTPCT_EL0 and CNTVCT_EL0.
Performance Monitors support

The ARMv8 architecture defines optional Performance Monitors.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter.
- Up to a maximum of 32 IMPLEMENTATION DEFINED event counters, where the number is identified by the PMCR_EL0.N field.
- System register access to the cycle counter and event registers, and related controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Generating interrupts on overflow.

Software can enable the cycle counter independently of the event counters.

Software executing at EL1 or a higher Exception level, for example an operating system, can enable access to the counters from EL0. This allows an application to monitor its own performance with fine grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

For details on the features, configuration and control of the Performance Monitors, see Chapter D5 The Performance Monitors Extension.

EL0 access to Performance Monitors

To allow application code to make use of the Performance Monitors, software executing at a higher Exception level must set the following bits in the PMUSERENR_EL0 system register:

- **EN** When set to 1, access to all Performance Monitors registers is allowed at EL0, except for writes to PMUSERENR_EL0, and reads/writes of PMINTENSET_EL1 and PMINTENCLR_EL1.
- **ER** When set to 1, read access to event counters is allowed at EL0. This includes read/write access to PMSELR_EL0, so that the event counter to read through PMXEVCNTR_EL0 can be set.
- **CR** When set to 1, read access to PMCCNTR_EL0 is allowed at EL0.
- **SW** When set to 1, write access to PMSWINC_EL0 is allowed at EL0.

--- Note ---

Register PMUSERENR_EL0 is always read-only at EL0.
B1.3 Software control features and EL0

The following sections describe the EL0 view of the ARMv8 software control features:

- Exception handling
- Wait for Interrupt and Wait for Event
- The YIELD instruction
- Application level cache management
- Debug events on page B1-68

B1.3.1 Exception handling

In the ARM architecture, an exception causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- System calls.
- Secure monitor or Hypervisor traps.

Most details of exception handling are not visible to application level software, and are described in Chapter D1 The AArch64 System Level Programmers’ Model.

The SVC instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

B1.3.2 Wait for Interrupt and Wait for Event

Issuing a WFI instruction indicates that no further execution is required until a WFI wake-up event occurs, see Wait For Interrupt on page D1-1598. This permits entry to a low-power state.

Issuing a WFE instruction indicates that no further execution is required until a WFE wake-up event occurs, see Wait for Event mechanism and Send event on page D1-1595. This permits entry to a low-power state.

B1.3.3 The YIELD instruction

The YIELD instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see YIELD on page C6-804. This mechanism can be used to improve overall performance in a Symmetric Multi-Threading (SMT) or Symmetric Multi-Processing (SMP) system.

Examples of when the YIELD instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop but in an SMP system is modified. The YIELD instruction permits binary compatibility between SMT and SMP systems.

The YIELD instruction is a NOP (No Operation) hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

B1.3.4 Application level cache management

A small number of cache management instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 system register. Any access from EL0 to an operation with the access right disabled causes the instruction to behave as an UNDEFINED instruction.

About the available operations, see Application level cache instructions on page B2-74.
B1.3.5 Debug events

The debug logic is responsible for generating debug events. Most aspects of debug events are not visible to application level software, and are described in Chapter H1 Introduction to External Debug. Aspects that are visible to application level software include:

- The BKPT instruction, which causes a BKPT instruction debug event to occur.
- The DBG instruction, which provides a hint to the debug system.
- The HLT instruction, which causes entry to Debug state.
Chapter B2
The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- Address space on page B2-70.
- Memory type overview on page B2-71.
- Caches and memory hierarchy on page B2-72.
- Alignment support on page B2-77.
- Endian support on page B2-78.
- Atomicity in the ARM architecture on page B2-81.
- Memory ordering on page B2-84.
- Memory types and attributes on page B2-93.
- Mismatched memory attributes on page B2-104.
- Synchronization and semaphores on page B2-107.

Note
In this chapter, system register names usually link to the description of the register in Chapter D7 AArch64 System Register Descriptions, for example SCTLR_EL1.
B2.1 Address space

Address calculations are performed using 64-bit registers. However, supervisory software can configure the top eight address bits for use as a tag, as described in Address tagging in AArch64 state on page D4-1726. If this is done, address bits[63:56]:

• Are not considered when determining whether the address is valid.
• Are never propagated to the program counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo $2^{64}$.

The result of an address calculation is UNKNOWN if it overflows or underflows:

• The 64-bit address range $A[63:0]$, where tagged addressing is not used.
• The 56-bit address range $A[55:0]$, where tagged addressing is used.

Memory accesses use the $\text{Mem}[]$ function.

The $\text{Mem}[]$ function makes an access of the required type. If supervisory software configures the top eight address bits for use as a tag, the top eight address bits are ignored.

```plaintext
bits(size=8) Mem[bids(64) address, integer size, AccType acctype]
assert size IN {1, 2, 4, 8, 16};
Mem[bids(64) address, integer size, AccType acctype] = bits(size=8) value;
```

The $\text{AccType}$ enumeration defines the different access types:

```plaintext
enumeration AccType {AccType_NORMAL, AccType_VEC,        // Normal loads and stores
AccType_STREAM, AccType_VECSTREAM,  // Streaming loads and stores
AccType_ATOMIC,                     // Atomic loads and stores
AccType_ORDERED,                     // Load-Acquire and Store-Release
AccType_UNPRIV,                     // Load and store unprivileged
AccType_IFETCH,                      // Instruction fetch
AccType_PTW,                         // Page table walk
AccType_DC,                         // Data cache maintenance
AccType_IC,                         // Instruction cache maintenance
AccType_AT};                        // Address translation
```

---Note---

• Chapter D3 The AArch64 System Level Memory Model and Chapter D4 The AArch64 Virtual Memory System Architecture include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.

• For information on the pseudocode that relates to memory accesses, see Basic memory access on page D3-1715, Unaligned memory access on page D3-1716, and Aligned memory access on page D3-1715.
B2.2 Memory type overview

ARMv8 provides the following mutually-exclusive memory types:

**Normal**
This is generally used for bulk memory operations, both read-write and read-only operations.

**Device**
The ARM architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See Gathering on page B2-100.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See Reordering on page B2-101.
- They indicate whether a write can be acknowledged other than at the end point. See Early Write Acknowledgement on page B2-101.

For more information on Normal memory and Device memory, see Memory types and attributes on page B2-93.

__Note__

Earlier versions of the ARM architecture defined a single Device memory type and a Strongly-Ordered memory type. A Note in Device memory on page B2-98 describes how these memory types map onto the ARMv8 memory types.
B2.3 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. ARMv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Application level cache instructions on page B2-74
- Implication of caches for the application programmer on page B2-74.
- Preloading caches on page B2-76.

B2.3.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a tag.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

**Spatial locality**

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

**Temporal locality**

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access occurs to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. ARMv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.3.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B2-1 on page B2-73 shows an example of such a system in an ARMv8-A system that supports virtual addressing.
Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined by two conceptual points:

**Point of Unification (PoU)**

The point at which the instruction cache, data cache, and translation table walks of a particular PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged. The point of unification might coincide with the point of coherency.

**Point of Coherency (PoC)**

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

---

**Note**

The presence of system caches can affect the definition of point of coherency as described in [System level caches on page D3-1710](#).

---

**See also** [Overview of the cache maintenance instructions on page D3-1696](#).

---

**The cacheability and shareability memory attributes**

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

- **Cacheability**
  This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer cacheability locations.

- **Shareability**
  This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer shareability domains.
B2.3.3 Application level cache instructions

In the ARM architecture, the application level is defined as Exception level 0 (EL0). The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable EL0 access to the following:

- The data cache maintenance instructions, DC CVAU, DC CVAC, and DC CIVAC. See Data cache maintenance instructions (DC*) on page D3-1701.
- The instruction cache maintenance instruction, IC IVAU. See Instruction cache maintenance instructions (IC*) on page D3-1701.
- The cache type register. See CTR_EL0.
- The data cache zero instruction, DC ZVA. See Data cache zero instruction on page D3-1708.

These instructions are UNDEFINED from EL0 unless software executing at a higher Exception level has enabled them. See Cache maintenance instructions on page D3-1700.

For all of these instructions, if the addresses do not have read access permission at EL0, executing these instructions at EL0 generates a Permission fault.

For more information about the system controls, see Cache support on page D3-1691.

B2.3.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  — Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  — Not enabling caches in the system.
- By using cache maintenance instructions to manage the coherency issues in software. See Application level cache instructions.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory on page B2-95 and Shareable, Inner Shareable, and Outer Shareable Normal memory on page B2-94.
Note

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Note

Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context synchronization operation on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory. In the absence of an ISB, there is no limit on the number of times such an instruction might be executed without being re-fetched from memory.

The ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using the ISB and DSB memory barriers and cache maintenance instructions. The following code sequence can be used to allow a PE to execute code that the same PE has written.

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
    STR Wt, [Xn]
    DC CVAU, Xn         ; Clean data cache by VA to point of unification (PoU)
    DSB ISH             ; Ensure visibility of the data cleaned from cache
    IC IVAU, Xn         ; Invalidate instruction cache by VA to PoU
    DSB ISH             ; Ensure completion of the invalidations
    ISB                 ; Synchronize the fetched instruction stream

Note

- For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the ARMv8-A AArch64 architecture allows Non-cacheable accesses to be held in an instruction cache. See Non-cacheable accesses and instruction caches on page D3-1696.
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See Concurrent modification and execution of instructions on page B2-83.
- The system software controls whether these cache maintenance instructions are available to the application level by setting SCTLR_EL1.UCI.
B2.3.5 Preloading caches

The ARM architecture provides memory system hints `PRFM`, `LDNP`, and `STNP` that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as `NOP` s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous external abort, which is taken using an SError interrupt exception. For more information, see Exception from a Data abort on page D1-1530.

PrefetchHint{} defines the prefetch hint types:

```
enumeration PrefetchHint {Prefetch_READ, Prefetch_WRITE, Prefetch_EXEC};
```

The Hint_Prefetch() function signals to the memory system that memory accesses of the type `hint` to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint `stream`.

```
Hint_Prefetch(bits(64) address, PrefetchHint hint, integer target, boolean stream);
```

For more information on `PRFM` and Load/Store instructions that provide hints to the memory system, see Prefetch memory on page C3-149 and Load/Store SIMD and Floating-point Non-temporal pair on page C3-147.
### B2.4 Alignment support

This section describes alignment support. It contains the following subsections:

- *Instruction alignment.*
- *Alignment of data accesses.*
- *Unaligned data access restrictions.*

#### B2.4.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a Misaligned PC fault. See [PC alignment checking](#) on page D1-1509.

#### B2.4.2 Alignment of data accesses

An unaligned access to any type of Device memory causes an Alignment fault.

The alignment requirements for accesses to Normal memory are as follows:

- For all instructions that load or store a single or multiple registers, other than Load-Exclusive/Store-Exclusive and Load-Acquire/Store-Release, if the address that is accessed is not aligned to the size of the data element being accessed, then one of the following occurs:
  - An Alignment fault is generated.
  - An unaligned access is performed.

  `SCTLR_ELx.A` at the current Exception level can be configured to enable an alignment check, and thereby determine which of these two options is used.

  **Note**
  
  - The `SCTLR_EL1.A` bit that is applicable to software running at EL0, can only be accessed from EL1 or above.
  - Alignment checks are based on element size, not overall access size. This affects SIMD element and structure loads and stores, and also Load/Store pair instructions.

- For all Load-Exclusive/Store-Exclusive and Load-Acquire/Store-Release memory accesses that access a single element or a pair of elements, an Alignment fault is generated if the address being accessed is not aligned to the size of the data structure being accessed.

A failed alignment check results in an Alignment fault, which is taken as a Data Abort exception. These exceptions are taken to the lowest Exception level that can handle the exception, consistent with the basic requirement that the Exception level never decreases on taking an exception. Therefore:

- Alignment faults taken from EL0 or EL1 are taken to EL1 unless redirected by `HCR_EL2.TGE`
- Alignment faults taken from EL2 are taken to EL2.
- Alignment faults taken from EL3 are taken to EL3.

#### B2.4.3 Unaligned data access restrictions

The following points apply to unaligned data accesses in ARMv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see [Atomicity in the ARM architecture](#) on page B2-81.

- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.

- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.
B2.5 Endian support

General description of endianness in the ARM architecture describes the relationship between endianness and memory addressing in the ARM architecture.

The following subsections then describe the endianness schemes supported by the architecture:

• Instruction endianness on page B2-79.
• Data endianness on page B2-79.

B2.5.1 General description of endianness in the ARM architecture

This section only describes memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B2-2 shows, for big-endian and little-endian memory systems, the relationship between:

• The quadword at address A.
• The doubleword at address A and A+8.
• The words at addresses A, A+4, A+8, and A+12.
• The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
• The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in Figure B2-2 have the following definitions:

B_A Byte at address A.
HW_A Halfword at address A.
MSByte Most-significant byte.
LSByte Least-significant byte.

Figure B2-2 Endianness relationships
The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word or halfword are interpreted. For example, a load of a word from address 0x1000 always results in an access to the bytes at memory locations 0x1000, 0x1001, 0x1002, and 0x1003. The endianness mapping scheme determines the significance of these four bytes.

### B2.5.2 Instruction endianness

In ARMv8-A, A64 instructions have a fixed length of 32 bits and are always little-endian.

### B2.5.3 Data endianness

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores.

For more information see *Endianness in SIMD operations*.

#### Instructions to reverse bytes in a general-purpose register or a SIMD and floating-point register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table B2-1 shows the instructions that provide this functionality:

<table>
<thead>
<tr>
<th>Function</th>
<th>Instructions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reverse bytes in 32-bit word or wordsa</td>
<td>REV32</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>
<td>Reverse bytes in whole register</td>
<td>REV</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>
<td>Reverse bytes in 16-bit halfwords</td>
<td>REV16</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>
<td>Reverse elements in doublewords, vector</td>
<td>REV64</td>
<td>For use with SIMD and floating-point registers</td>
</tr>
<tr>
<td>Reverse elements in words, vector</td>
<td>REV32</td>
<td>For use with SIMD and floating-point registers</td>
</tr>
<tr>
<td>Reverse elements in halfwords, vector</td>
<td>REV16</td>
<td>For use with SIMD and floating-point registers</td>
</tr>
</tbody>
</table>

a. Can operate on multiple words.

#### Endianness in SIMD operations

SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

LD1 {V0.4H}, [X1]
This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

![Figure B2-3 SIMD byte order example](image)

The `BigEndian()` function determines the current endianness of the data:

```cpp
boolean BigEndian();
```

The pseudocode function for `BigEndianReverse()` is as follows:

```cpp
// BigEndianReverse()
// ==============

bits(width) BigEndianReverse (bits(width) value)
assert width IN {8, 16, 32, 64, 128};
integer half = width DIV 2;
if width == 8 then return value;
return BigEndianReverse(value<half-1:0>) : BigEndianReverse(value<width-1:half>);
```
B2.6 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as atomic accesses. The ARM architecture description refers to two types of atomicity, defined in:

- Single-copy atomicity.
- Multi-copy atomicity on page B2-82.

In the ARMv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- Memory type overview on page B2-71.
- Requirements for single-copy atomicity.
- Requirements for multi-copy atomicity on page B2-82.

B2.6.1 Single-copy atomicity

A read or write operation is single-copy atomic only if it meets the following conditions:

1. For a single-copy atomic store, if the store overlaps another single-copy atomic store, then all of the writes from one of the stores are inserted into the Coherence order of each overlapping byte before any of the writes of the other store are inserted into the Coherence orders of the overlapping bytes.

2. If a single-copy atomic load overlaps a single-copy atomic store and for any of the overlapping bytes the load returns the data written by the write inserted into the Coherence order of that byte by the single-copy atomic store then the load must return data from a point in the Coherence order no earlier than the writes inserted into the Coherence order by the single-copy atomic store of all of the overlapping bytes.

B2.6.2 Requirements for single-copy atomicity

For explicit memory accesses generated from an Exception level the following rules apply:

- All reads generated by load instructions that load a single general-purpose register and that are aligned to the size of the read in that instruction are single-copy atomic.
- All writes generated by store instructions that store a single general-purpose register and that are aligned to the size of the write in that instruction are single-copy atomic.
- Reads of general-purpose registers generated by Load Pair instructions that are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes of general-purpose registers generated by Store pair instructions that are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.
- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

Note

To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.
- For the atomicity of instruction fetches, see Concurrent modification and execution of instructions on page B2-83.
- Reads to floating-point and SIMD registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being loaded are treated as single-copy atomic reads.
• Writes from floating-point and SIMD registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic writes.

• Element or Structure Reads to floating-point and SIMD registers of 64-bit or smaller elements, where each element is aligned to the size of the element being loaded, have each element treated as a single-copy atomic read.

• Element or Structure Writes from floating-point and SIMD registers of 64-bit or smaller elements, where each element is aligned to the size of the element being stored, have each element treated as a single-copy atomic store.

• Reads to floating-point and SIMD registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.

• Writes from floating-point and SIMD registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

--- Note ---

In AArch64 state, no memory accesses from a DC ZVA have single-copy atomicity of any quantity greater than individual bytes.

---

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated. See also Taking an interrupt or other exception during a multiple-register load or store on page D1-1557.

--- Note ---

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

---

### B2.6.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are multi-copy atomic if the following conditions are both true:

- All writes to the same location are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

--- Note ---

Writes that are not coherent are not multi-copy atomic.

---

### B2.6.4 Requirements for multi-copy atomicity

In a multiprocessing system, coherent writes to a memory location are multi-copy atomic if the read of a location returns the value of a write only when all observers have observed that write.

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory with the non-Gathering attribute, writes that are single-copy atomic are also multi-copy atomic.

For Device memory with the Gathering attribute, writes are not required to be multi-copy atomic.
B2.6.5 Concurrent modification and execution of instructions

The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification is a B, BL, NOP, BRK, SVC, HVC, or SMC instruction.

For the B, BL, NOP, BRK, SVC, HVC, and SMC instructions the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

• The instruction originally fetched.
• A fetch of the modified instruction.

If one thread of execution changes a conditional branch instruction, such as B or BL, to another conditional instruction and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

• The old condition being associated with the new target address.
• The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

For all other instructions, to avoid UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, the PE that modified the instructions must issue the following sequence of instructions and operations:

   ; Coherency example for data and instruction accesses within the same Inner Shareable domain.
   ; Enter this code with <Wt> containing a new 32-bit instruction,
   ; to be held in Cacheable space at a location pointed to by Xn.
   STR Wt, [Xn]
   DC CVAU, Xn ; Clean data cache by VA to point of unification (PoU)
   DSB ISH ; Ensure visibility of the data cleaned from cache
   IC IVAU, Xn ; Invalidate instruction cache by VA to PoU
   DSB ISH ; Ensure completion of the invalidations

   ——— Note ———
   The DC CVAU operation is not required if the area of memory is either Non-cacheable or Write-through Cacheable.

   ——— Note ———
   In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

   ISB ; Synchronize fetched instruction stream

   For more information about the required synchronization operation, see Synchronization and coherency issues between data and instruction accesses on page B2-75.

   ——— Note ———
   For information about memory accesses caused by instruction fetches, see Ordering requirements on page B2-85.
B2.7 Memory ordering

This section describes observation ordering. It contains the following subsections:

- Observability and completion.
- Ordering requirements on page B2-85.
- Memory barriers on page B2-87.
- Summary of the memory ordering rules on page B2-91.

For information on endpoint ordering of memory accesses, see Reordering on page B2-101.

In the ARMv8 memory model, the shareability memory attribute indicates whether hardware must ensure memory coherency.

The ARMv8 memory system architecture defines additional attributes and associated behaviors, defined in the system level section of this manual. See:

- Chapter D3 The AArch64 System Level Memory Model.
- Chapter D4 The AArch64 Virtual Memory System Architecture.

See also Mismatched memory attributes on page B2-104.

B2.7.1 Observability and completion

An observer is a master in the system that is capable of observing memory accesses. For a PE, the following mechanisms must be treated as independent observers:

- The mechanism that performs reads or writes to memory.
- A mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory. These are treated as reads.
- A mechanism that performs translation table walks. These are treated as reads.

The set of observers that can observe a memory access is defined by the system.

In the definitions in this subsection, subsequent means whichever of the following is appropriate to the context:

- After the point in time where the location is observed by that observer.
- After the point in time where the location is globally observed.

For all memory:

- A write to a location in memory is said to be observed by an observer when:
  - A subsequent read of the location by the same observer returns the value written by the observed write, or written by a write to that location by any observer that is sequenced in the Coherence order of the location after the observed write.
  - A subsequent write of the location by the same observer is sequenced in the Coherence order of the location after the observed write.

- A write to a location in memory is said to be globally observed for a shareability domain or set of observers when:
  - A subsequent read of the location by any observer in that shareability domain returns the value written by the globally observed write, or written by a write to that location by any observer that is sequenced in the Coherence order of the location after the globally observed write.
  - A subsequent write of the location by any observer in that shareability domain is sequenced in the Coherence order of the location after the globally observed write.

- A read of a location in memory is said to be observed by an observer when a subsequent write to the location by the same observer has no effect on the value returned by the read.

- A read of a location in memory is said to be globally observed for a shareability domain when a subsequent write to the location by any observer in that shareability domain has no effect on the value returned by the read.
Additionally, for Device-nGnRnE memory:

- A read or write of a memory-mapped location in a peripheral that exhibits side-effects is said to be observed, and globally observed, only when the read or write:
  - Meets the general conditions listed.
  - Can begin to affect the state of the memory-mapped peripheral.
  - Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

  **Note**

  This definition is consistent with the memory access having reached the peripheral.

For all memory, the completion rules are defined as:

- A read or write is complete for a shareability domain when all of the following are true:
  - The read or write is globally observed for that shareability domain.
  - Any translation table walks associated with the read or write are complete for that shareability domain.

- A translation table walk is complete for a shareability domain when the memory accesses associated with the translation table walk are globally observed for that shareability domain, and the TLB is updated.

- A cache or TLB maintenance instruction is complete for a shareability domain when the effects of the instruction are globally observed for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

### Completion of side-effects of accesses to Device memory

The completion of a memory access to Device memory other than Device-nGnRnE is not guaranteed to be sufficient to determine that the side-effects of the memory access are visible to all observers. The mechanism that ensures the visibility of side-effects of a memory access is IMPLEMENTATION DEFINED.

#### B2.7.2 Ordering requirements

ARMv8 defines restrictions for the permitted ordering of memory accesses. These restrictions depend on the memory locations that are being accessed. See Memory types and attributes on page B2-93.

The following additional restrictions apply to the order in which accesses to Normal memory are observed:

- Reads and writes can be observed in any order provided the following constraints are met:
  - If an address dependency exists between two reads or between a read and a write, then those memory accesses are observed in program order by all observers within the shareability domain of the memory address being accessed.
    
    The ARMv8 architecture relaxes this rule for execution where the second read is generated by a Load Non-Temporal Pair instruction. See Load/Store Non-temporal Pair on page C3-143 and Load/Store SIMD and Floating-point Non-temporal pair on page C3-147.
  - Writes that would not occur in a simple sequential execution of the program cannot be observed by other observers. This implies that where a control, address or data dependency exists between a read and a write, those memory accesses are observed in program order by all observers within the shareability domain of the memory addresses being accessed.
  - Ordering can be achieved by using a DMB or DSB barrier. For more information on DMB and DSB instructions, see Memory barriers on page B2-87.
  - Reads and writes to the same location are coherent within the shareability domain of the memory address being accessed.
Two reads of the same location by the same observer are observed in program order by all observers within the shareability domain of the memory address being accessed.

Writes are not required to be multi-copy atomic. This means that in the absence of barriers, the observation of a store by one observer does not imply the observation of the store by another observer.

Instructions that access multiple elements have no defined ordering requirements for the memory accesses relative to each other.

Memory accesses caused by instruction fetches are not required to be observed in program order, unless they are separated by an ISB or other context synchronization event.

### Address dependencies and order

In the ARMv8 architecture, a register data dependency creates order between a load instruction and a subsequent memory transaction, that is between the data value returned from the load and the address used by the subsequent memory transaction.

A register data dependency exists between a first data value and a second data value when either:

- The register, excluding the zero register (XZR or WZR), used to hold the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:
  - A conditional branch whose condition is determined by the first data value.
  - A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.

- There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

_____ Note _____

A register data dependency can exist even if the value of the first data value is discarded as part of the calculation, as might be the case if it is ANDed with 0x0 or if arithmetic using the first data value cancels out its contribution.

For example, each of the following code sequences creates order between the memory transactions:

**Sequence 1**
```
LDR X1, [X2]
AND X1, X1, XZR
LDR X4, [X3, X1]
```

**Sequence 2**
```
LDR X1, [X2]
ADD X3, X3, X1
SUB X3, X3, X1
STR X4, [X3]
```

### Address dependencies of Load Non-temporal Pair instructions

Where an address dependency exists between two reads, and the second read was generated by a Load Non-temporal Pair instruction, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by other observers within the shareability domain of the memory addresses being accessed.

This affects the following instruction:

- **LDNP** on page C6-524.
B2.7.3 Memory barriers

The ARM architecture is a weakly ordered memory architecture that supports out of order completion. Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the ARMv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the ARMv8 memory barrier instructions:

- Instruction Synchronization Barrier (ISB)
- Data Memory Barrier (DMB).
- Data Synchronization Barrier (DSB)
- Shareability and access limitations on the data barrier operations
- Load-Acquire, Store-Release

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

Instruction Synchronization Barrier (ISB)

An ISB instruction flushes the pipeline in the PE, so that all instructions that come after the ISB instruction in program order are fetched from the cache or memory only after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to system control registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

InstructionSynchronizationBarrier();

See also Memory barriers on page D3-1722.

Data Memory Barrier (DMB)

The DMB instruction is a data memory barrier. The PE that executes the DMB instruction is referred to as the executing PE, PEe. The DMB instruction takes the required shareability domain and required access types as arguments:

DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);

See Shareability and access limitations on the data barrier operations on page B2-89.

If the required shareability is Full system then the operation applies to all observers within the system.

A DMB creates two groups of memory accesses, Group A and Group B:

Group A Contains:

- All explicit memory accesses of the required access types from observers in the same required shareability domain as PEe that are observed by PEe before the DMB instruction. These accesses include any accesses of the required access types performed by PEe.
All loads of required access types from an observer \textit{PEx} in the same required shareability domain as \textit{PEe} that have been observed by any given different observer, \textit{PEy}, in the same required shareability domain as \textit{PEe} before \textit{PEy} has performed a memory access that is a member of Group A.

\textbf{Group B} Contains:

- All explicit memory accesses of the required access types by \textit{PEe} that occur in program order after the \textit{DMB} instruction.
- All explicit memory accesses of the required access types by any given observer \textit{PEx} in the same required shareability domain as \textit{PEe} that can only occur after a load by \textit{PEx} has returned the result of a store that is a member of Group B.

Any observer with the same required shareability domain as \textit{PEe} observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a \textit{DMB NSH} is sufficient for this guarantee.

\textbf{Note}

- A memory access might be in neither Group A nor Group B. The \textit{DMB} does not affect the order of observation of such a memory access.
- The second part of the definition of Group A is recursive. Ultimately, membership of Group A derives from the observation by \textit{PEy} of a load before \textit{PEy} performs an access that is a member of Group A as a result of the first part of the definition of Group A.
- The second part of the definition of Group B is recursive. Ultimately, membership of Group B derives from the observation by any observer of an access by \textit{PEe} that is a member of Group B as a result of the first part of the definition of Group B.

\textit{DMB} only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see \textit{Cache maintenance instructions} on page D3-1700. It has no effect on the ordering of any other instructions executing on the PE. A \textit{DMB} instruction intended to ensure the completion of cache maintenance operations must have an access type of both loads and stores.

See also \textit{Memory barriers} on page D3-1722.

\textbf{Data Synchronization Barrier (DSB)}

The \textit{DSB} instruction is a special memory barrier, that synchronizes the execution stream with memory accesses.

The \textit{DSB} instruction takes the \textit{required shareability domain} and \textit{required access types} as arguments:

\texttt{DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);}

See \textit{Shareability and access limitations on the data barrier operations} on page B2-89.

If the required shareability is \textit{Full system} then the operation applies to all observers within the system.

A \textit{DSB} behaves as a \textit{DMB} with the same arguments, and also has the additional properties defined in this section. The PE that executes the \textit{DSB} instruction is referred to as the executing PE, \textit{PEe}.

A \textit{DSB} completes when all of the following apply:

- All explicit memory accesses that are observed by \textit{PEe} before the \textit{DSB} is executed and are of the required access types, and are from observers in the same required shareability domain as \textit{PEe}, are complete for the set of observers in the required shareability domain.
• If the required access types of the DSB is reads and writes, all cache maintenance instructions issued by PEr before the DSB are complete for the required shareability domain.

• If the required access types of the DSB is reads and writes, all TLB maintenance instructions issued by PEr before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can execute until the DSB completes.

A DSB intended to ensure the completion of cache maintenance operations must have an access type of both loads and stores.

See also Memory barriers on page D3-1722.

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions take an argument that specifies:
• The shareability domain over which the instruction must operate. This is one of:
  — Full system.
  — Outer Shareable.
  — Inner Shareable.
  — Non-shareable.
• The accesses for which the instruction operates. This is one of:
  — Read and write accesses in Group A and Group B.
  — Write accesses only in Group A and Group B.
  — Read access only in Group A and read and write accesses in Group B.

Note

This is occasionally referred to as a Load-Load/Store barrier.

See the instruction descriptions for more information about these arguments.

Note

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation.
Load-Acquire, Store-Release

ARMv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. See Load-Acquire/Store-Release on page C3-145.

For all memory types, these instructions have the following ordering requirements:

• A Store-Release followed by a Load-Acquire is observed in program order by any observers that are in both:
  — The shareability domain of the address accessed by the Store-Release.
  — The shareability domain of the address accessed by the Load-Acquire.

• For a Load-Acquire, observers in the shareability domain of the address accessed by the Load-Acquire observe accesses in the following order:
  1. The read caused by the Load-Acquire.
  2. Reads and writes caused by loads and stores that appear in program order after the Load-Acquire for which the shareability of the address accessed by the load or store requires that the observer observes the access. There are no other ordering requirements on loads or stores that appear before the Load-Acquire.

There are no additional ordering requirements on loads or stores that appear before the Load-Acquire.

• For a Store-Release, observers in the shareability domain of the address accessed by the Store-Release observe accesses in the following order:
  1. All of the following for which the shareability of the address accessed requires that the observer observes the access:
     • Reads and writes caused by loads and stores that appear in program order before the Store-Release.
     • Writes that were observed by the PE executing the Store-Release before it executed the Store-Release.
  2. The write caused by the Store-Release.

There are no other ordering requirements on loads or stores that appear in program order after the Store-Release.

• A Store-Release instruction is multi-copy atomic when observed with a Load-Acquire instruction.

In addition, for accesses to a memory-mapped peripheral of an arbitrary system-defined size that is defined using Device memory, these instructions have the following requirements:

• A Load-Acquire to an address in the memory-mapped peripheral will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.

• A Store-Release to an address in the memory-mapped peripheral will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.

• Any memory access to the memory-mapped peripheral that are architecturally required to be ordered before the memory access of a Store-Release will arrive at the memory-mapped peripheral before any memory access to the same memory-mapped peripheral that are architecturally required to be ordered after the memory access of a Load-Acquire to the same memory location as the Store-Release, where the Load-Acquire has observed the value stored by the Store-Release.

Load-Acquire and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements. The address supplied to the instructions must be aligned to twice the size of the element being loaded, otherwise the access generates an Alignment fault.
A Store-Release Exclusive instruction only has the release semantics if the store is successful.

--- Note ---

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.

---

**B2.7.4 Summary of the memory ordering rules**

The following is a concise list of the situations that are required, by the ARM architecture specification, to cause externally-visible order of memory. This ordering means that if memory transaction A has externally visible order ahead of memory transaction B, then all observers within the shareability domains of A and B will observe A before B. See *Terms used in the summary of the memory ordering rules* for definitions of the terms used.

--- Note ---

This list applies to both AArch32 state and AArch64 state, and is consistent with the requirements of ARMv7.

1. **DMB** and **DSB** barrier instructions, and load acquire/store release instructions, create externally-visible order as defined by those instructions.

2. A True or False Address dependency from a Load to a Load or from a Load to a Store creates externally-visible order.

3. A True Control dependency from a Load to an **ISB** instruction creates externally-visible order between the load and any memory accesses after the **ISB** instruction.

4. A True Register data dependency from a Load to a Store creates externally-visible order.

5. A True Control dependency from a Load to a Store creates externally-visible order.

6. Memory is coherent within the shareability domain of a memory location, which means there is a total order of all writes to that location that all observers within that shareability domain will agree on.

--- Note ---

A consequence of this is that reads to the same location by the same PE are observed in order.

7. A Dependency from a Store to a Load through memory between different PEs creates externally-visible order but stores are not multi-copy atomic except where explicitly defined to be by the definition of the store.

--- Note ---

A consequence of the lack of multi-copy atomicity is that a Store to Load dependency through memory on the same PE does not create externally-visible order.

No other effects are required to create externally visible order in the ARM architecture.

**Terms used in the summary of the memory ordering rules**

The summary uses the following terms:

**Register data dependency**

This is defined in *Address dependencies and order* on page B2-86.
False Register data dependency
A False Register data dependency is a Register data dependency where no register in the system holds a variable for which a change of the first data value causes a change of the second data value.

True Register data dependency
A True Register data dependency is a Register data dependency that is not a false Register data dependency.

True Address dependency
A True Address dependency between a load and a subsequent memory transaction exists where there is a True Register data dependency between the data value returned from the load and the address used by the subsequent memory transaction.

False Address dependency
A False Address dependency between a load and a subsequent memory transaction exists where there is a False Register data dependency between the data value returned from the load and the address used by the subsequent memory transaction.

True Control dependency
A True Control dependency between a load and a subsequent instruction exists:
• Where there is a True Register data dependency between the data value returned from the load and data value used in the evaluation of a conditional branch and the subsequent instruction is only executed as a result of one of the possible outcomes of that conditional branch.
• Where there is a True Register data dependency between the data value returned from the load and the data value used in the evaluation of a subsequent instruction that is a conditional selection, move, or computation for which both:
  — The condition is determined by the returned data value.
  — No input data value for the selection, move, or computation has a register data dependency on the returned data value.

Dependency from a Store to a Load through memory
A Dependency from a Store to a Load through memory exists where the Store and Load are to the same physical address, and value returned by the Load is the value that was written by the Store, and could not be the value that was previously held in that memory location.
B2.8 Memory types and attributes

In ARMv8 the ordering of accesses for locations of memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory on page B2-98.
- Memory access restrictions on page B2-102.

B2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.
- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.
- Writes to a memory location with the Normal memory attribute that are Non-cacheable must reach the endpoint for that location in the memory system in finite time.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See Multi-register loads and stores that access Normal memory on page B2-97.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.

An instruction that generates a sequence of accesses as described in Atomicity in the ARM architecture on page B2-81 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory on page B2-94.
- Non-shareable Normal memory on page B2-95.
- Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory on page B2-95.
See also:

- Multi-register loads and stores that access Normal memory on page B2-97.
- Atomicity in the ARM architecture on page B2-81.
- Memory barriers on page B2-87. For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.
- Concurrent modification and execution of instructions on page B2-83.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

- Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
- Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see Synchronization and coherency issues between data and instruction accesses on page B2-75.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The ARM architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
• The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. Example B2-1 shows how they might be used.

**Example B2-1 Use of shareability attributes**

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

• In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.

• However, between the two clusters, the caches:
  — Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  — Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

**Non-shareable Normal memory**

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

**Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory**

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a cacheability attribute that is one of:

• Write-Through Cacheable.
• Write-Back Cacheable.
• Non-cacheable.

Also, for cacheable Normal memory regions:

• A region might be assigned a cache allocation hint.

• It is IMPLEMENTATION DEFINED whether the Write-Through Cacheable and Write-Back Cacheable attributes can have an additional attribute of Transient or Non-transient, see Transient cacheability attribute on page B2-97.
A memory location can be marked as having different cacheability attributes, for example when using aliases in a virtual to physical address mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases see Mismatched memory attributes on page B2-104.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

Note
Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the ARM architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the inner and the outer cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example B2-2, Example B2-3 on page B2-97, and Example B2-4 on page B2-97 describe the possible ways of implementing a system with three levels of cache, level 1 (L1) to level 3 (L3).

Note
- L1 cache is the level closest to the PE, see Memory hierarchy on page B2-72.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example B2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.
Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

**Transient cacheability attribute**

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient attribute is supported for cacheable Normal memory regions. If an implementation supports this attribute, the set of possible cacheability attributes for a Normal memory region becomes:

- Write-Through Cacheable, Non-transient.
- Write-Back Cacheable, Non-transient.
- Write-Through Cacheable, Transient.
- Write-Back Cacheable, Transient.
- Non-cacheable.

The cacheability attribute can be defined independently for the inner and outer levels of caching.

The transient attribute indicates that the benefit of caching is for a relatively short period. Therefore it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

--- Note ---

The architecture does not specify what is meant by a relatively short period.

The description of the AArch64 MAIR_EL1, MAIR_EL2, and MAIR_EL3 registers, and the AArch32 MAIR0, MAIR1, HMAIR0, and HMAIR1 registers, includes the assignment of the Transient attribute in an implementation that supports this option.

**Multi-register loads and stores that access Normal memory**

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more SIMD and floating-point register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.
B2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for ARMv8 Device memory are:

- **Gathering** identified as G or nG, see "Gathering" on page B2-100.
- **Reordering** identified as R or nR, see "Reordering" on page B2-101.
- **Early Write Acknowledgement hint** identified as E or nE, see "Early Write Acknowledgement" on page B2-101.

The ARMv8 Device memory types are:

- **Device-nGnRnE** Device non-Gathering, non-Reordering, No Early write acknowledgement. Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.
- **Device-nGnRE** Device non-Gathering, non-Reordering, Early Write Acknowledgement. Equivalent to the Device memory type in earlier versions of the architecture.
- **Device-nGRE** Device non-Gathering, Reordering, Early Write Acknowledgement. ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.
- **Device-GRE** Device Gathering, Reordering, Early Write Acknowledgement. ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

Collectively these are referred to as any Device memory type. Going down the list, the memory types are described as getting weaker; conversely the going up the list the memory types are described as getting stronger.

--- Note ---

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.

- The architecture does not require an implementation to distinguish between each of these memory types and ARM recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

- Earlier versions of the ARM architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  Three exceptions to this apply:
  - Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
— For Device memory with the Gathering attribute, reads generated by the LDNP instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.

— Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See Single-copy atomicity on page B2-81.

Note

— An instruction that generates a sequence of accesses as described in Atomicity in the ARM architecture on page B2-81 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, ARM strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

— Write speculation that is visible to other observers is prohibited for all memory types.

• A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.

• If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.

• A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.

• Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.

• A memory location with any Device memory attribute cannot be allocated into a cache.

• Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.

• All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

Note

In the Non-secure EL1 translation regime in systems where HCR_EL2.TGE == 1 and HCR_EL2.DC == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS.[24] to be 0.

• Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

Note

This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

The memory types for Translation table walks cannot be defined as any Device memory type within the TCR_ELx. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device.
memory type. These accesses might be made speculatively. When the value of the \texttt{HCR\_EL2\_PTW} bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

**Gathering**

In the Device memory attribute:

\texttt{G} Indicates that the location has the Gathering attribute.

\texttt{nG} Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

\textbf{Note}\n
This also applies to writebacks from the cache, whether caused by a \textit{Natural eviction} or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All accesses occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See \textit{Multi-register loads and stores that access Device memory} on page B2-102.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted. This applies if one memory access is in Group A and one memory access is in Group B. That is, gathering is not permitted between a memory access in Group A and a memory access in Group B if the two accesses are separated by a barrier that affects at least one of the accesses.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

\textbf{Note}\n
- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a \texttt{DMB} or \texttt{DSB} barrier that affects both of the accesses, for example if one access is in Group A and the other is in Group B.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
The ARM architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the Non-gathering attribute.

An implementation is not permitted to perform an access with the Non-gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

\[\text{R}\] Indicates that the location has the Reordering attribute.

\[\text{nR}\] Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.

- The ARM architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.

- Accesses with the non-Reordering attribute and accesses to Normal memory.

- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

Early Write Acknowledgement

In the Device memory attribute:

\[\text{E}\] Indicates that the location has the Early Write Acknowledgement attribute.

\[\text{nE}\] Indicates that the location has the No Early Write Acknowledgement attribute.

Early Write Acknowledgement is a hint to the platform memory system. Assigning the No Early Write Acknowledgement attribute to a Device memory location recommends that only the endpoint of the write access returns a write acknowledgement of the access, and that no earlier point in the memory system returns a write.
acknowledge. This means that a DSB barrier, executed by the PE that performed the write to the No Early Write Acknowledgement location, completes only after the write has reached its endpoint in the memory system. Typically, this endpoint is a peripheral or physical memory.

When the Early Write Acknowledgement attribute is assigned to a Device memory location, there is no such recommendation for the handling of accesses to that location.

--- Note ---

• The Early Write Acknowledgement hint has no effect on the ordering rules. The purpose of signaling no Early Write Acknowledgement is to signal to the interconnect that the peripheral requires the ability to signal the acknowledgement. The No Write Acknowledgement signal also provides an additional semantic that can be interpreted by the driver that is accessing the peripheral.

• This attribute is treated as a hint, as the exact nature of the interconnects accessed by a PE is outside the scope of the ARM architecture definition, and not all interconnects provide a mechanism to ensure that a write has reached the physical endpoint of the memory system.

• ARM recommends that writes with the No Early Write Acknowledgement hint are used for PCIe configuration writes. However, the mechanisms by which PCIe configuration writes are identified are IMPLEMENTATION DEFINED.

• ARM strongly recommends that the Early Write Acknowledgement hint is not ignored by a PE, but is made available for use by the system.

Because the No Early Write Acknowledgement attribute is a hint:

• An implementation is permitted to perform an access with the Early Write Acknowledgement attribute in a manner consistent with the requirements specified by the No Early Write Acknowledgement attribute.

• An implementation is permitted to perform an access with the No Early Write Acknowledgement attribute in a manner consistent with the relaxations allowed by the Early Write Acknowledgement attribute.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more floating-point and SIMD register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions, even for access to any type of Device memory.

B2.8.3 Memory access restrictions

The following restrictions apply to memory accesses:

• For accesses to any two bytes, p and q, that are generated by the same instruction:
  — The bytes p and q must have the same memory type and shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LD1, ST1, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  — Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for bytes p and q.

For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or shareability attributes on page J1-5443.
• The accesses of an instruction that causes multiple accesses to any type of Device memory must not cross a 4KB address boundary, otherwise the effect is CONSTRAINED UNPREDICTABLE. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.

______ Note _______

This situation is CONSTRAINED UNPREDICTABLE even if the cause of the accesses is an unaligned access to any type of Device memory in an implementation that includes the Virtualization Extensions.

ARM expects this restriction to impose constraints on the placing of volatile memory devices in the memory map of a system, rather than expecting a compiler to be aware of the alignment of memory accesses.

For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a peripheral boundary with a Device access on page J1-5443.
B2.9 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see Chapter D4 The AArch64 Virtual Memory System Architecture.

Physical memory locations are accessed with mismatched attributes if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

——— Note ————

The terms location and memory location refer to any byte within the current coherency granule and are used interchangeably.

When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
  — A read of the memory location by one agent might not return the value most recently written to that memory location by the same agent.
  — Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.

- There might be a loss of coherency when multiple agents attempt to access a memory location.

- There might be a loss of properties derived from the memory type, as described in later bullets in this section.

- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.

- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Re-ordering.

For the following situations, when a physical memory location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. If the only memory type mismatch associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.

2. Any agent that reads that memory location using the same common definition of the shareability and cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all of the following conditions are met:

   - All aliases to the memory location with write permission both use a common definition of the shareability and cacheability attributes for the memory location, and either:
     — Have the inner cacheability attribute the same as the outer cacheability attribute.
     — In the Non-secure EL1 translation regime, have HCR_EL2.MIOCNCE set to 0.

   - All aliases to a memory location use a definition of the shareability attributes that encompasses all the agents with permission to access the location.
3. The possible software-visible effects caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
   • Any Device memory type.
   • Normal Inner Non-cacheable, Outer Non-cacheable memory.

   In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   • Possible loss of properties derived from the memory type when multiple agents attempt to access the memory location.
   • Possible reordering of memory transactions to the same memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting \texttt{DMB} barrier instructions between accesses to the same memory location that might use different attributes.

   Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

   1. If the mismatched attributes for a memory location all assign the same shareability attribute to the location, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable locations between agents in different shareability domains. This means:
      • Before writing to a location not using the Write-Back attribute, software must invalidate, or clean, a location from the caches if any agent might have written to the location with the Write-Back attribute. This avoids the possibility of overwriting the location with stale data.
      • After writing to a location with the Write-Back attribute, software must clean the location from the caches, to make the write visible to external memory.
      • Before reading the location with a cacheable attribute, software must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.

      In all cases:
      • Location refers to any byte within the current coherency granule.
      • A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
      • In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see \textit{Ordering and completion of data and instruction cache instructions on page D3-1706}.

      \textbf{Note} \hspace{1cm}

      With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

      \textbf{Note} \hspace{1cm}

      The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

2. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:
   • Each PE that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.
   • A \texttt{DMB} barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory location that use different attributes.

      \textbf{Note} \hspace{1cm}

      The Note in rule 1 of this list, about possible race conditions, also applies to this rule.
In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes **UNKNOWN**.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.
Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using synchronization primitives. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

--- Note
Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table B2-2 shows the synchronization primitives and the associated CLREX instruction.

---

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address \( x \) is:

- The Load-Exclusive instruction reads a value from memory address \( x \).
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address \( x \) only if no other observer, process, or thread has performed a more recent store to address \( x \). The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block on page B2-113. A Store-Exclusive instruction to any address in the marked block clears the marking.

--- Note
In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.
B2.10.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a local monitor that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:
- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state
- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If the local monitor is in the Open Access state
- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:
- If the write is to a physical address that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

Figure B2-4 on page B2-109 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.
For the local monitor state machine, as shown in Figure B2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

### Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B2-4.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B2-4 must not indefinitely delay forward progress of execution.
B2.10.2 Exclusive access instructions and Shareable memory locations

For memory locations with a Shareability attribute of Inner Shareable or Outer Shareable, exclusive access instructions rely on:

- A local monitor for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations on page B2-108, except that for Shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A global monitor that marks a physical address as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

—— Note ———

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE, see Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-113.

—— Note ———

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The implementation defined aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For Shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

—— Note ———

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all ARM PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.
Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:

- Inner shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The set of memory types that support atomic instructions must include all of the memory types for which a global monitor is implemented.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an external abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault Status code of ESR_ELx.DFSC = 110101. The priority of this fault is IMPLEMENTATION DEFINED.
- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by ARM PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

**Operation of the global monitor**

A Load-Exclusive instruction from Shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

---

**Note**

The global monitor only supports a single outstanding exclusive access to Shareable memory per PE.

---

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
• If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  — If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  — If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to Shareable memory by PE(n) can respond to all the Shareable memory accesses visible to it. This means it responds to:
• Accesses generated by PE(n).
• Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

**Clear global monitor event**

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Mechanisms for entering a low-power state* on page D1-1595.

*Figure B2-5* shows the state machine for PE(n) in a global monitor.

---

**Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system**

For more information about marking see *Marking and the size of the marked memory block* on page B2-113.

---

**Note**

For the global monitor state machine, as shown in *Figure B2-5*:

• The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
• Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked Shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B2-5 on page B2-112 only shows how the operations by (n) cause state transitions of the state machine for PE(n).

• A Load-Exclusive instruction can only update the marked Shareable memory address for the PE issuing the Load-Exclusive instruction.

• When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

• It is IMPLEMENTATION DEFINED:
  — Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  — Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.10.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a LDXR instruction is executed, a marked block of size $2^a$ is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. For example, in an implementation where $a$ is 4, a successful LDXR of address 0x341B4 defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

The size of the marked memory block is called the Exclusives Reservation Granule. The Exclusives Reservation Granule is IMPLEMENTATION DEFINED in the range 2 - 512 words:

• 3 words in an implementation where $a$ is 4.
• 512 words in an implementation where $a$ is 11.

In some implementations the CTR identifies the Exclusives Reservation Granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives Reservation Granule, 512 words, is implemented.

B2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

Note
Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

B2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDXP/STXP pair or a LDXR/STXR pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a LoadExcl/StoreExcl pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive pairs shown in Table B2-2 on page B2-107:

• The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target virtual address of a StoreExcl is different from the virtual address of the preceding
LoadExcl instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, a LoadExcl/StoreExcl pair can only be relied upon to eventually succeed if the LoadExcl and the StoreExcl are executed with the same virtual address.

- If two StoreExcl instructions are executed without an intervening LoadExcl instruction the second StoreExcl instruction returns a status value of 1. This means that:
  - ARM recommends that, in a given thread of execution, every StoreExcl instruction has a preceding LoadExcl instruction associated with it.

  It is not necessary for every LoadExcl instruction to have a subsequent StoreExcl instruction.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a Store-Exclusive instruction is the same as the transaction size of the preceding Load-Exclusive instruction executed in that thread. If the transaction size of a Store-Exclusive instruction is different from the preceding Load-Exclusive instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, software can rely on an LoadExcl/StoreExcl pair to eventually succeed only if they have the same size.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the Store-Exclusive instruction accesses the same number of registers as the preceding Load-Exclusive instruction executed in that thread. If the Store-Exclusive instruction accesses a different number of registers than the preceding Load-Exclusive instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. As a result, software can rely on an LoadExcl/StoreExcl pair to eventually succeed only if they access the same number of registers. For more information see UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers on page B2-115.

- An implementation might clear an exclusive monitor between the LoadExcl instruction and the StoreExcl instruction without any application-related cause. For example, this might happen because of cache evictions. Software must, in any single thread of execution, avoid having any explicit memory accesses, system control register updates, or cache maintenance instructions between the LoadExcl instruction and the associated StoreExcl instruction.

- Implementations can benefit from keeping the LoadExcl and StoreExcl operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the LoadExcl instruction and the StoreExcl instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between LoadExcl and StoreExcl instructions in a single thread of execution.

- The architecture sets an upper limit of 2048 bytes on the exclusive reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule. This is a performance guideline rather than a functional requirement.

- After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN.

- For the memory location accessed by a LoadExcl/StoreExcl pair, if the memory attributes for the LoadExcl instruction differ from the memory attributes for the StoreExcl instruction, behavior is UNPREDICTABLE.

  This can occur either:
  - Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  - As a result of using different virtual addresses, with different attributes, that point to the same physical address. This case is covered by another bullet point in this list.

- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is UNPREDICTABLE. The instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.
Note

ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

• If the mapping of the virtual to physical address is changed between the LDREX instruction and the STREX instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when updating translation table entries on page D4-1830, if the STREX is performed after another write to the same physical address as the STREX, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the STREX will not pass its monitor check.

Note

ARM expects that, in many implementations, either:
— The TLB invalidation will clear either the local or global monitor.
— The physical address will be checked between the LDREX and STREX.

Note

In the event of repeatedly-contending Load-Exclusive/Store-Exclusive instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers

As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED UNPREDICTABLE if, in a single thread of execution, either:

• An LDXP instruction of two 32-bit quantities is followed by an STXR instruction of one 64-bit quantity at the same address.

• An LDXR instruction of one 64-bit quantity is followed by an STXP instruction of two 32-bit quantities at the same address.

In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:

• The STXP or STXR instruction generates an external Data Abort.

• The STXP or STXR instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Fault Status code of ESR_ELx.DFSC = 0b110101.

• The STXP or STXR instruction always fails, returning a status of 1.

• The STXP or STXR instruction always passes, returning a status of 0.

• This STXP or STXR instruction has the same pass or fail behavior that it would have had if the instruction had used the same size and number of registers as the preceding LDXR or LDXP instruction.

B2.10.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, and SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in Wait for Event mechanism and Send event on page D1-1595. However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.
**Note**
This is equivalent to issuing an SEV instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.
Part C
The AArch64 Instruction Set
Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- *Introduction* on page C1-120.
- *Structure of the A64 assembler language* on page C1-121.
- *Address generation* on page C1-126.
- *Instruction aliases* on page C1-129.
C1.1 Introduction

The instruction set supported in the AArch64 Execution state is known as A64.

All A64 instructions have a width of 32 bits. The A64 encoding structure breaks down into the following functional groups:

- A miscellaneous group of branch instructions, exception generating instructions, and system instructions.
- Data processing instructions associated with general-purpose registers. These instructions are supported by two functional groups, depending on whether the operands:
  - Are all held in registers.
  - Include an operand with a constant immediate value.
- Load and store instructions associated with the general-purpose register file and the SIMD and floating-point register file.
- SIMD and scalar floating-point data processing instructions that operate on the SIMD and floating-point registers.

The encoding hierarchy within a functional group breaks down as follows:

- A functional group consists of a set of related instruction classes. A64 instruction index by encoding on page C4-184 provides an overview of the instruction encodings in the form of a list of instruction classes within their functional groups.
- An instruction class consists of a set of related instruction forms. Instruction forms are documented in one of two alphabetic lists:
  - The load, store, and data processing instructions associated with the general-purpose registers, together with those in the other instruction classes. See Chapter C6 A64 Base Instruction Descriptions.
  - The load, store, and data processing instructions associated with the SIMD and floating-point support. See Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions.
- An instruction form might support a single instruction syntax. Where an instruction supports more than one syntax, each syntax is an instruction variant. Instruction variants can occur because of differences in:
  - The size or format of the operands.
  - The register file used for the operands.
  - The addressing mode used for load/load/store memory operands.

Instruction variants might also arise as the result of other factors.

Instruction variants are described in the instruction description for the individual instructions.

A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data processing instructions. See The stack pointer registers on page D1-1499.
  - Indicate the value zero when used as a source register operand.
  - Indicate discarding the result when used as a destination register operand.

For SIMD and floating-point register access, the value used selects one of 32 registers.

- Immediate bits that provide constant data processing values or address offsets are placed in contiguous bit fields. Some computed values in instruction variants use one or more immediate bit fields together with the secondary encoding bit fields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction results in an Undefined Instruction exception, unless otherwise defined in the Exception model.
C1.2 Structure of the A64 assembler language

The letter $W$ denotes a general-purpose register holding a 32-bit word, and $X$ denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both upper-case and lower-case variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either upper-case or lower-case mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the `#` character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the `#` character. ARM recommends that an A64 disassembler outputs a `#` before an immediate operand.

In Example C1-1 on page C1-122 the sequence `//` is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.1 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

- **UPPER**: Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name $Xn$ indicates that the $X$ is required, followed by a variable register number, for example $X29$.
- **<>**: Any text enclosed by angle braces, `< >`, is a value that the user supplies. Subsequent text might supply additional information.
- **{}**: Any item enclosed by curly brackets, `{ }`, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.
- **[]**: Any items enclosed by square brackets, `[ ]`, constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.
- **a|b**: Alternative words are separated by a vertical bar, `|`, and can be surrounded by parentheses to delimit them. For example, $U(ADD|SUB)W$ represents $UADDW$ or $USUBW$.
- **±**: This indicates an optional + or - sign. If neither is used then + is assumed.
- **uimm**: An $n$-bit unsigned, positive, immediate value.
- **simm**: An $n$-bit two’s complement, signed immediate value, where $n$ includes the sign bit.
- **SP**: See Register names on page C1-122.
- **Wn**: See Register names on page C1-122.
- **WSP**: See Register names on page C1-122.
- **WZR**: See Register names on page C1-122.
- **Xn**: See Register names on page C1-122.
- **XZR**: See Register names on page C1-122.

C1.2.2 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following A00 instructions all have different opcodes. However, the programmer must only remember one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.
### Example C1-1  ADD instructions with different opcodes

- `ADD W0, W1, W2` // add 32-bit register
- `ADD X0, X1, X2` // add 64-bit register
- `ADD X0, X1, W2, SXTW` // add 64-bit extended register
- `ADD X0, X1, #42` // add 64-bit immediate

### C1.2.3 Condition Code

The A64 ISA has some instructions that set condition flags or test condition codes or both. For information about instructions that set the condition flags or use the condition mnemonics, see *Condition flags and related instructions* on page C6-402.

Table C1-1 shows the available condition codes.

#### Table C1-1 Condition codes

<table>
<thead>
<tr>
<th>cond</th>

</table>

- **a.** Unordered means at least one NaN operand.
- **b.** The condition code NV exists only to provide a valid disassembly of the 0b1111 encoding, otherwise its behavior is identical to AL.

### C1.2.4 Register names

This section describes the AArch64 registers. It contains the following subsections:

- *General-purpose register file and the stack pointer* on page C1-123.
- *SIMD and floating-point register file* on page C1-123.
- *SIMD and floating-point scalar register names* on page C1-124.
- *SIMD vector register names* on page C1-124.
• **SIMD vector element names on page C1-124.**

### General-purpose register file and the stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. A general-purpose register field that encodes the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

Table C1-2 shows the qualified names for registers, where \( n \) is a register number 0-30.

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wn</td>
<td>32 bits</td>
<td>0-30</td>
<td>General-purpose register 0-30</td>
</tr>
<tr>
<td>Xn</td>
<td>64 bits</td>
<td>0-30</td>
<td>General-purpose register 0-30</td>
</tr>
<tr>
<td>WZR</td>
<td>32 bits</td>
<td>31</td>
<td>Zero register</td>
</tr>
<tr>
<td>XZR</td>
<td>64 bits</td>
<td>31</td>
<td>Zero register</td>
</tr>
<tr>
<td>WSP</td>
<td>32 bits</td>
<td>31</td>
<td>Current stack pointer</td>
</tr>
<tr>
<td>SP</td>
<td>64 bits</td>
<td>31</td>
<td>Current stack pointer</td>
</tr>
</tbody>
</table>

The following list provides further details relating to Table C1-2.

• The names Xn and Wn both refer to the same general-purpose register, Rn.

• There is no register named W31 or X31.

• The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.

• The name WSP represents the current stack pointer in a 32-bit context.

• The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.

• The name WZR represents the zero register in a 32-bit context.

• The architecture does not define a special name for general-purpose register R30 that reflects its special role as the link register on procedure calls. An A64 assembler must always use W30 and X30. Additional software names might be defined as part of the Procedure Call Standard, see *Procedure Call Standard for the ARM 64-bit Architecture*.

### SIMD and floating-point register file

The 32 registers in the SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See *General-purpose register file and the stack pointer.*
Note

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials or cryptographic hashes.

SIMD and floating-point scalar register names

SIMD and floating-point instructions that operate on scalar data only access the lower bits of a SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-3 shows the qualified names for accessing scalar SIMD and floating-point registers. The letter $n$ denotes a register number between 0 and 31.

<table>
<thead>
<tr>
<th>Size</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>B$n$</td>
</tr>
<tr>
<td>16 bits</td>
<td>H$n$</td>
</tr>
<tr>
<td>32 bits</td>
<td>S$n$</td>
</tr>
<tr>
<td>64 bits</td>
<td>D$n$</td>
</tr>
<tr>
<td>128 bits</td>
<td>Q$n$</td>
</tr>
</tbody>
</table>

SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD, manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-4 shows the SIMD vector register names. The letter $n$ denotes a register number between 0 and 31.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits × 8 lanes</td>
<td>V$n$.8B</td>
</tr>
<tr>
<td>8 bits × 16 lanes</td>
<td>V$n$.16B</td>
</tr>
<tr>
<td>16 bits × 4 lanes</td>
<td>V$n$.4H</td>
</tr>
<tr>
<td>16 bits × 8 lanes</td>
<td>V$n$.8H</td>
</tr>
<tr>
<td>32 bits × 2 lanes</td>
<td>V$n$.2S</td>
</tr>
<tr>
<td>32 bits × 4 lanes</td>
<td>V$n$.4S</td>
</tr>
<tr>
<td>64 bits × 1 lane</td>
<td>V$n$.1D</td>
</tr>
<tr>
<td>64 bits × 2 lanes</td>
<td>V$n$.2D</td>
</tr>
</tbody>
</table>

SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.
Table C1-5 shows the vector register names and the element index. The letter $i$ denotes the element index.

<table>
<thead>
<tr>
<th>Size</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>$V_n.B[i]$</td>
</tr>
<tr>
<td>16 bits</td>
<td>$V_n.H[i]$</td>
</tr>
<tr>
<td>32 bits</td>
<td>$V_n.S[i]$</td>
</tr>
<tr>
<td>64 bits</td>
<td>$V_n.D[i]$</td>
</tr>
</tbody>
</table>

An assembler must accept a fully qualified SIMD register name, if the number of lanes is greater than the index value. See **SIMD vector register names** on page C1-124. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register $V_9$:

- $V_9.2S[1]$  //optional number of lanes
- $V_9.4S[1]$  //optional number of lanes

**Note**
The SIMD and floating-point register element name $V_n.S[0]$ is not equivalent to the scalar SIMD and floating-point register name $S_n$. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

**SIMD vector register list**

Where an instruction operates on multiple SIMD and floating-point registers, for example vector Load/Store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register number are increasing. The following examples are equivalent representations of a set of four registers $V_4$ to $V_7$, each holding four lanes of 32-bit elements:

- $\{ V_4.4S - V_7.4S \}$  //standard disassembly
- $\{ V_4.4S, V_5.4S, V_6.4S, V_7.4S \}$  //alternative representation

**SIMD vector element list**

Registers in a list can also have a vector element form. For example, the $Ld4$ instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

- $\{ V_4.5 - V_7.5 \}[3]$  //standard disassembly
- $\{ V_4.4S, V_5.4S, V_6.4S, V_7.4S \}[3]$  //alternative with optional number of lanes
C1.3 Address generation

The A64 instruction set supports 64-bit addresses. The valid address range is determined by the following factors:

- The size of the implemented virtual address space.
- Memory Management Unit (MMU) configuration settings.

The top 8 bits of the 64-bit address can be used as a tag, see *Address tagging in AArch64 state on page D4-1726.* For more information on memory management and address translation, see Chapter D4 *The AArch64 Virtual Memory System Architecture.*

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative Load/Store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/Store addressing modes

Load/Store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, SP, with an optional immediate or register offset. Table C1-6 shows the assembler syntax for the complete set of Load/Store addressing modes.

<table>
<thead>
<tr>
<th>Addressing Mode</th>
<th>Immediate</th>
<th>Offset</th>
<th>Extended Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base register only (no offset)</td>
<td>[base, #0]</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Base plus offset</td>
<td>[base, #imm]</td>
<td>[base, Xm{, LSL #imm}]</td>
<td>[base, Wm, (S</td>
</tr>
<tr>
<td>Pre-indexed</td>
<td>[base, #imm]!</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Post-indexed</td>
<td>[base], #imm</td>
<td>[base], Xm#</td>
<td>-</td>
</tr>
<tr>
<td>Literal (PC-relative)</td>
<td>label</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

a. The post-indexed by register offset mode can be used with the SIMD Load/Store structure instructions described in *Load/Store Vector on page C3-148.* Otherwise the post-indexed by register offset mode is not available.
Some types of Load/Store instruction support only a subset of the Load/Store addressing modes listed in Table C1-6 on page C1-126. Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can only be used for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of Load/Store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of Load/Store instruction and the transfer size.

Table C1-7 shows the offset and the type of Load/Store instruction.

<table>
<thead>
<tr>
<th>Offset bits</th>
<th>Sign</th>
<th>Scaling</th>
<th>Write-Back</th>
<th>Load/Store type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>Exclusive/acquire/release</td>
</tr>
<tr>
<td>7</td>
<td>Signed</td>
<td>Scaled</td>
<td>Optional</td>
<td>Register pair</td>
</tr>
<tr>
<td>9</td>
<td>Signed</td>
<td>Unscaled</td>
<td>Optional</td>
<td>Single register</td>
</tr>
<tr>
<td>12</td>
<td>Unsigned</td>
<td>Scaled</td>
<td>No</td>
<td>Single register</td>
</tr>
</tbody>
</table>

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if \( \text{LSL} \ #\text{imm} \) is present and where \( \text{imm} \) must be equal to \( \log_2(\text{transfer\_size}) \).
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by \( \#\text{imm} \), where \( \text{imm} \) must be equal to \( \log_2(\text{transfer\_size}) \). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific Load/Store instruction requires this. SP cannot be used as a register offset.

**Address calculation**

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.
Table C1-8 shows the arithmetic instructions that can compute addressing modes.

Table C1-8 Arithmetic instructions to compute addressing modes

<table>
<thead>

<td>-</td>
</tr>
</tbody>
</table>

---

Note

- To calculate a base plus immediate offset the ADD instructions defined in *Arithmetic (immediate)* on page C3-151 accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single ADD instruction cannot support the full range of byte offsets available to a single register Load/Store with a scaled 12-bit immediate offset. For example, a quadword LDR effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two ADD instructions. The following example shows this:

  `ADD Xd, base, #(imm & 0xFFF)`
  `ADD Xd, Xd, #(imm>>12), LSL #12`

- To calculate a base plus extended register offset, the ADD instructions defined in *Arithmetic (extended register)* on page C3-156 provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

  `ADD Xd, base, Wm, SXTW #3`  // Xd = base + (SignExtend(Wm) LSL 3)
  `ADD Xd, base, Wm, UXTH #4`  // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)

- If the same extended register offset is used by more than one Load/Store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then re-use it as a simple register offset. The extend and scale calculation can be performed using the SBFIZ and UBFIZ bitfield instructions defined in *Bitfield move* on page C3-153, for example:

  `SBFIZ Xd, Xm, #3, #32`  // Xd = “Wm, SXTW #3”
  `UBFIZ Xd, Xm, #4, #16`  // Xd = “Wm, UXTH #4”
C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.
C1 The A64 Instruction Set
C1.4 Instruction aliases
Chapter C2
About the A64 Instruction Descriptions

This chapter describes the instruction descriptions contained in Chapter C6 *A64 Base Instruction Descriptions* and Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

It contains the following section:

- *Understanding the A64 instruction descriptions on page C2-132.*
C2.1 Understanding the A64 instruction descriptions

Each instruction description in Chapter C6 and Chapter C7 has the following content:

1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in Chapter C6 there are the following titles for different forms of the \texttt{ADD} instruction:

- \texttt{ADD (extended register)} on page C6-406.
- \texttt{ADD (immediate)} on page C6-409.
- \texttt{ADD (shifted register)} on page C6-411.

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:

- Post-index.
- Pre-index.
- Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address $A$ shows, from left to right, the bytes at addresses $A+3$, $A+2$, $A+1$, and $A$.

There might be variants of an encoding, if the assembler syntax prototype differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in Chapter C6 there are the following subheadings for variants of the \texttt{ADC} instruction encoding:

- 32-bit variant ($sf = 0$).
- 64-bit variant ($sf = 1$).

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.
Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See Pseudocode describing how the instruction operates on page C2-134.

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

ARM recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The Assembler symbols subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

- **< >** Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

- **{ }** Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

- **#** This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. ARM recommends that disassemblers output the # where the assembler syntax prototype includes it.

- **+-** This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

- **<Xn>** The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).

- **<Wn>** The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).

- **<Xn|SP>** The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).

- **<Wn|WSP>** The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).

- **<Bn>, <Hn>, <Sn>, <Dn>, <Qn>** The 8, 16, 32, 64 or 128-bit name of a SIMD and floating-point register in a scalar context as described in Register names on page C1-122.

- **<Vn>** The name of a SIMD and floating-point register name in a vector context as described in Register names on page C1-122.

If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.
C2 About the A64 Instruction Descriptions
C2.1 Understanding the A64 instruction descriptions

——— Note ————
Register names on page C1-122 provides the A64 register names.

C2.1.6 Pseudocode describing how the instruction operates

The Operation subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

——— Note ————
For a description of ARM pseudocode, see Appendix J9 ARM Pseudocode Definition. This appendix also describes the execution model for an instruction.

C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.
Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- **Branches, Exception generating, and System instructions** on page C3-136.
- **Loads and stores** on page C3-140.
- **Data processing - immediate** on page C3-151.
- **Data processing - register** on page C3-156.
- **Data processing - SIMD and floating-point** on page C3-163.

For a structured breakdown of instruction groups by encoding, see Chapter C4 *A64 Instruction Set Encoding.*
C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and system instructions. It contains the following subsections:

- Conditional branch.
- Unconditional branch (immediate).
- Unconditional branch (register) on page C3-137.
- Exception generation and return on page C3-137.
- System register instructions on page C3-138.
- System instructions on page C3-138.
- Hint instructions on page C3-139.
- Barriers and CLREX instructions on page C3-139.

For information about the encoding structure of the instructions in this instruction group, see Branches, exception generating and system instructions on page C4-185.

Note

Software must:

- Use only BLR or BL to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the BLR or BL instruction incremented by four.
- Use only RET to perform a subroutine return, when that subroutine is expected to have been entered by a BL or BLR instruction.
- Use only B, BR, or the instructions listed in Table C3-1 to perform a control transfer that is not a subroutine call or subroutine return described in this Note.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the current state of the condition flags or the value in a general-purpose register. See Table C1-1 on page C1-122 for a list of the condition codes that can be used for cond.

Table C3-1 shows the Conditional branch instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>Branch offset range from the PC</th>
<th>See</th>
</tr>
</thead>
<tbody>

<td>TBZ on page C6-782</td>
</tr>
</tbody>
</table>

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The BL instruction also writes the address of the sequentially following instruction to general-purpose register, X30.
Table C3-2 shows the Unconditional branch instructions with an immediate branch offset.

### Table C3-2 Unconditional branch instructions (immediate)

<table>

<td>B on page C6-435</td>
</tr>
<tr>
<td>BL</td>
<td>Branch with link</td>
<td>±128MB</td>
<td>BL on page C6-444</td>
</tr>
</tbody>
</table>

### C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The **BLR** instruction also writes the address of the sequentially following instruction to general-purpose register X30. The **RET** instruction behaves identically to **BR**, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

For more information about the barriers, see Memory barriers on page B2-87.

For information about the allocated values for the data barriers, see:
- DMB on page C6-487.
- DSB on page C6-490.
C3.2 Loads and stores

This section describes the Load/Store instructions. It contains the following subsections:

- Load/Store register.
- Load/Store register (unscaled offset) on page C3-141.
- Load/Store Pair on page C3-142.
- Load/Store Non-temporal Pair on page C3-143.
- Load/Store Unprivileged on page C3-143.
- Load-Exclusive/Store-Exclusive on page C3-144.
- Load-Acquire/Store-Release on page C3-145.
- Load/Store scalar SIMD and floating-point on page C3-145.
- Prefetch memory on page C3-149.

Apart from Load-Exclusive, Store-Exclusive, Load-Acquire, and Store-Release, addresses can have any alignment unless strict alignment checking is enabled, that is if SCTLR_ELx.A == 1.

The additional control bits SCTLR_ELx.SA and SCTLR_EL1.SA0 control whether the stack pointer must be quadword aligned when used as a base register. See Stack pointer alignment checking on page D1-1510. Using a misaligned stack pointer generates a Stack Alignment exception.

For information about the encoding structure of the instructions in this instruction group, see Loads and stores on page C4-188.

Note

In some cases, Load/Store instructions can lead to CONSTRANDED UNPREDICTABLE behavior. See Constraints on AArch64 state UNPREDICTABLE behaviors on page J1-5440.

C3.2.1 Load/Store register

The Load/Store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also Load/Store addressing modes on page C1-126.

If a Load instruction specifies writeback and the register being loaded is also the base register, then one of the following behaviors occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store instruction performs a writeback and the register that is stored is also the base register, then one of the following behaviors occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-11 shows the Load/Store Register instructions.

</tr>
</tbody>
</table>

#### C3.2.2 Load/Store register (unscaled offset)

The Load/Store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/Store addressing modes on page C1-126.

The Load/Store register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:

- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a Load/Store instruction, for example LDR, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-12 on page C3-142. ARM recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a Load/Store single register mnemonic, for example, LDR.
Table C3-12 shows the Load/Store register instructions with an unscaled offset.

<table>

</tr>
<tr>
<td>STURH</td>
<td>Store halfword (unscaled offset)</td>
<td>STURH on page C6-746</td>
</tr>
</tbody>
</table>

### C3.2.3 Load/Store Pair

The Load/Store Pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-126.

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then one of the following behaviors occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then one of the following behaviors occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then one of the following behaviors occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.
Table C3-13 shows the Load/Store Pair instructions.

<tr>
<td>STP</td>
<td>Store Pair</td>
<td>STP on page C6-713</td>
</tr>
</tbody>
</table>

C3.2.4   Load/Store Non-temporal Pair

The Load/Store Non-temporal Pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See Load/Store addressing modes on page C1-126.

The Load/Store Non-temporal Pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition there is a special exception to the normal memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then one of the following can occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-14 shows the Load/Store Non-temporal Pair instructions.

</tbody>
</table>

C3.2.5   Load/Store Unprivileged

The Load/Store Unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/Store addressing modes on page C1-126.

The Load/Store Unprivileged instructions can be used when the PE is at EL1 to perform unprivileged memory accesses. If the PE is executing in any other Exception level, then the access permissions for that level apply.
Table C3-15 shows the Load/Store Unprivileged instructions.

</tbody>
</table>

### C3.2.6 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes on page C1-126*.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See *Synchronization and semaphores on page B2-107*.

Natural alignment is required and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair. When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location.

Table C3-16 shows the Load-Exclusive/Store-Exclusive instructions.

C3.2.7 Load-Acquire/Store-Release

The Load-Acquire/Store-Release instructions support only one addressing mode:

- Base register with no offset.

See Load/Store addressing modes on page C1-126.

The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of Load-Acquire/Store-Release, see Load-Acquire, Store-Release on page B2-90.

C3.2.8 Load/Store scalar SIMD and floating-point

The Load/Store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in SIMD and floating-point scalar register names on page C1-124. The memory addressing modes available, described in Load/Store addressing modes on page C1-126, are identical to the general-purpose register Load/Store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the Load/Store instructions that transfer general-purpose registers, Load/Store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.
Load/Store scalar SIMD and floating-point register

The Load/Store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see Load/Store addressing modes on page C1-126.

Note

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see Load/Store scalar SIMD and floating-point register (unscaled offset).

Table C3-19 shows the Load/Store instructions for a single SIMD and floating-point register.

Table C3-19 Load/Store single SIMD and floating-point register instructions

<td>• <strong>STR</strong>(immediate, SIMD&amp;FP) on page C7-1358</td>
</tr>
</tbody>
</table>

Load/Store scalar SIMD and floating-point register (unscaled offset)

The Load/Store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also Load/Store addressing modes on page C1-126.

The Load/Store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the Load/Store register (unscaled offset) instructions, that disambiguate this instruction class from the Load/Store register instruction, see Load/Store register (unscaled offset) on page C3-141.

Table C3-20 shows the Load/Store SIMD and floating-point register instructions with an unscaled offset.

</table>
Load/Store SIMD and Floating-point register pair

The Load/Store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/Store addressing modes on page C1-126.

If a Load pair instruction specifies the same register for the two registers that are being loaded, then one of the following occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-21 shows the Load/Store SIMD and floating-point register pair instructions.

<td>Store pair of scalar SIMD&amp;FP registers</td>
<td>STP (SIMD&amp;FP) on page C7-1355</td>
</tr>
</tbody>
</table>

Load/Store SIMD and Floating-point Non-temporal pair

The Load/Store SIMD and Floating-point Non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also Load/Store addressing modes on page C1-126.

The Load/Store Non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition there is a special exception to the normal memory ordering rules. If an address dependency exists between two memory reads, and a Load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-temporal pair instruction specifies the same register for the two registers that are being loaded, then one of the following occurs:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.
Table C3-22 shows the Load/Store SIMD and floating-point Non-temporal pair instructions.

C3.2.9 Load/Store Vector

The Vector Load/Store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
- Post-indexed by an immediate, equal to the number of bytes transferred.

Load/Store vector instructions, like other Load/Store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the Load/Store instructions that transfer general-purpose registers, the Load/Store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

Load/Store structures

Table C3-23 shows the Load/Store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

Table C3-23 Load/Store multiple structures instructions

### Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The prefetch memory instructions signal to the memory system that memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as pre-loading the specified address into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a PRFM instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is a SError interrupt.

A PRFM instruction can only have an effect on software visible structures, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution as defined in the translation regime of the current Exception level.

A PRFM instruction is guaranteed not to access Device memory.
A PRFM instruction using a PLI hint must not result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a PLI hint cannot access any memory location that cannot be accessed by instruction fetches.

The PRFM instructions require an additional <prfop> operand to be specified, which must be one of the following:

- PLDL1KEEP, PLDL1STRM, PLDL2KEEP, PLDL2STRM, PLDL3KEEP, PLDL3STRM
- PSTL1KEEP, PSTL1STRM, PSTL2KEEP, PSTL2STRM, PSTL3KEEP, PSTL3STRM
- PLIL1KEEP, PLIL1STRM, PLIL2KEEP, PLIL2STRM, PLIL3KEEP, PLIL3STRM

<prfop> is defined as <type><target><policy>.

Here:
- <type> Is one of:
  - PLD: Prefetch for load
  - PST: Prefetch for store
  - PLI: Preload instructions
- <target> Is one of:
  - L1: Level 1 cache
  - L2: Level 2 cache
  - L3: Level 3 cache
- <policy> Is one of:
  - KEEP: Retained or temporal prefetch, allocated in the cache normally
  - STRM: Streaming or non-temporal prefetch, for data that is used only once

PRFUM explicitly uses the unscaled 9-bit signed immediate offset addressing mode, as described in Load/Store register (unscaled offset) on page C3-141.

Table C3-25 shows the Prefetch memory instructions.

C3.3 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- Arithmetic (immediate).
- Logical (immediate).
- Move (wide immediate) on page C3-152.
- Move (immediate) on page C3-152.
- PC-relative address calculation on page C3-153.
- Bitfield move on page C3-153.
- Bitfield insert and extract on page C3-154
- Extract register on page C3-154.
- Shift (immediate) on page C3-154.
- Sign-extend and Zero-extend on page C3-154.

For information about the encoding structure of the instructions in this instruction group, see Data processing - immediate on page C4-205.

C3.3.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits. The Arithmetic (immediate) instructions that do not set condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-26 shows the Arithmetic instructions with an immediate offset.

<td>Compare</td>
<td>CMP (immediate) on page C6-466</td>
</tr>
<tr>
<td>CMN</td>
<td>Compare negative</td>
<td>CMN (immediate) on page C6-461</td>
</tr>
</tbody>
</table>

C3.3.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size $e = 2, 4, 8, 16, 32$ or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to $(e - 1)$ nonzero bits from bit 0 followed by zero bits, then rotated by 0 to $(e - 1)$ bits. This mechanism can generate 5334 unique 64-bit patterns as 2667 pairs of pattern and their bitwise inverse.

--- Note ---

Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.
### Note

Apart from **ANDS**, and its TST alias, Logical (immediate) instructions do not set the condition flags. However, the final results of a bitwise operation can be tested by a **CBZ**, **CBNZ**, **TBZ**, or **TBNZ** conditional branch.

Table C3-27 shows the Logical immediate instructions.

#### C3.3.3 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-28 shows the Move (wide immediate) instructions.

#### C3.3.4 Move (immediate)

The Move (immediate) instructions are aliases for a single **MOVZ**, **MOVN**, or **ORR** (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the **MOVZ**, **MOVN**, and **ORR** instruction to encode the immediate, then an assembler must prefer **MOVZ** to **MOVN**, and **MOVZ** or **MOVN** to **ORR**, to ensure reversibility. A disassembler must output **ORR** (immediate with zero register) **MOVZ**, and **MOVN**, as a **MOV** mnemonic except that the underlying instruction must be used when:

- **ORR** has an immediate that can be generated by a **MOVZ** or **MOVN** instruction.
- A **MOVN** instruction has an immediate that can be encoded by **MOVZ**.
- **MOVZ #0** or **MOVN #0** have a shift amount other than **LSL #0**.
Table C3-29 shows the Move (immediate) instructions.

</tr>
</tbody>
</table>

### C3.3.5 PC-relative address calculation

The ADR instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The ADRP instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an ADD (immediate) instruction, or a Load/Store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

**Note**

The term page used in the ADRP description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-30 shows the instructions used for PC-relative address calculations are as follows:

<table>
<thead>
<tr>
<th>Mnemonic</th>

</tr>
</tbody>
</table>

### C3.3.6 Bitfield move

The Bitfield move instructions copy a bitfield of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For BFM, the remaining bits are unchanged.
- For UBFM, the lower bits, if any, and upper bits, if any, are set to zero.
- For SBFM, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied bitfield.

Table C3-31 shows the Bitfield move instructions.

</tbody>
</table>

C3.3.8 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-33 shows the Extract (immediate) instructions.

C3.4 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- Arithmetic (shifted register).
- Arithmetic (extended register).
- Arithmetic with carry on page C3-157.
- Logical (shifted register) on page C3-158.
- Move (register) on page C3-159.
- Shift (register) on page C3-159.
- Multiply and divide on page C3-159.
- CRC32 on page C3-161.
- Bit operation on page C3-161.
- Conditional select on page C3-161.
- Conditional comparison on page C3-162.

For information about the encoding structure of the instructions in this instruction group, see Data processing - register on page C4-208.

C3.4.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR and LSR accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See Arithmetic (extended register) for arithmetic instructions that can operate on the current stack pointer.

Table C3-36 shows the Arithmetic (shifted register) instructions.

<td>NEG (shifted register) on page C6-641</td>
</tr>
<tr>
<td>NEGS</td>
<td>Negate and set flags</td>
<td>NEGS on page C6-643</td>
</tr>
</tbody>
</table>

C3.4.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.
The extended shift is described by the mandatory extend operator \(SXTB\), \(SXTH\), \(SXTW\), \(UXTB\), \(UXTH\), or \(UXTW\). This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms the additional operators \(UXTX\) and \(SXTX\) use all 64 bits of the second source register with an optional shift. In that case ARM recommends \(UXTX\) as the operator. If and only if at least one register is SP, ARM recommends use of the \(LSL\) operator name, rather than \(UXTX\), and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms the operators \(UXTW\) and \(SXTW\) both use all 32 bits of the second source register with an optional shift. In that case ARM recommends \(UXTW\) as the operator. If and only if at least one register is WSP, ARM recommends use of the \(LSL\) operator name, rather than \(UXTW\), and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions the final register operand is written as \(Wm\) for all except the \(UXTX/LSL\) and \(SXTX\) extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1 // SUB SP, SP, X1, UXTX #0
```

Table C3-37 shows the Arithmetic (extended register) instructions.

<table>
<thead>
<tr>

<td>(CMP) (extended register) on page C6-464</td>
</tr>
</tbody>
</table>

### C3.4.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-38 shows the Arithmetic with carry instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>

<td>(ADCS) on page C6-405</td>
</tr>
<tr>
<td>SBC</td>
<td>Subtract with carry</td>
<td>(SBC) on page C6-676</td>
</tr>
</tbody>
</table>
C3.4.4 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators $\text{LSL}$, $\text{ASR}$, $\text{LSR}$ and $\text{ROR}$ accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator and amount implies $\text{LSL} \ #0$, which means that there is no shift. A disassembler must not output $\text{LSL} \ #0$. However, a disassembler must output all other shifts by zero.

--- Note ---
Apart from $\text{ANDS}$, $\text{TST}$ and $\text{BICS}$ the logical instructions do not set the condition flags, but the final result of a bit operation can usually directly control a $\text{CBZ}$, $\text{CBNZ}$, $\text{TBZ}$, or $\text{TBNZ}$ conditional branch.

Table C3-39 shows the Logical (shifted register) instructions.

C3.4.5 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a
general-purpose register to another general-purpose register or the current stack pointer, or from the current stack
pointer to a general-purpose register.

Table C3-40 MOV register instructions

<table>
<thead>
<tr>
<th>Mnemonic</th>

<tr>
<td></td>
<td>Move register to SP or move SP to register</td>
<td>MOV (to/from SP) on page C6-621</td>
</tr>
</tbody>
</table>

C3.4.6 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the
register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift
or rotate at bit[63] or bit[31].

Table C3-41 shows the Shift (register) instructions.

C3.4.7 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following
subsections:

• Multiply on page C3-160.
• Divide on page C3-160.
Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using SMULH or UMULH to generate the upper 64 bits. Table C3-43 shows the Multiply instructions.

</tr>
</tbody>
</table>

Divide

The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the MSUB instruction.

If a signed integer division (\(\text{INT}_\text{MIN} / -1\)) is performed where \(\text{INT}_\text{MIN}\) is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is \(\text{INT}_\text{MIN}\).

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-44 shows the Divide instructions.

</table>
C3.4.8   CRC32

The optional CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32 and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of ID_AA64ISAR0_EL1 are set to 0b0001 the CRC instructions are implemented.

Table C3-45 shows the CRC instructions.

C3.4.10   Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might not be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.
Table C3-47 shows the Conditional select instructions.

### C3.4.11  Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-48 shows the Conditional comparison instructions.

C3.5 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

It contains the following subsections that describe the scalar floating-point data processing instructions:

• Floating-point move (register) on page C3-164.
• Floating-point move (immediate) on page C3-164.
• Floating-point conversion on page C3-165.
• Floating-point round to integral on page C3-166.
• Floating-point multiply-add on page C3-167.
• Floating-point arithmetic (one source) on page C3-167.
• Floating-point arithmetic (two sources) on page C3-167.
• Floating-point minimum and maximum on page C3-167.
• Floating-point comparison on page C3-168.
• Floating-point conditional select on page C3-168.

It also contains the following subsections that describe the SIMD data processing instructions:

• SIMD move on page C3-169
• SIMD arithmetic on page C3-169.
• SIMD compare on page C3-171.
• SIMD widening and narrowing arithmetic on page C3-172.
• SIMD unary arithmetic on page C3-173.
• SIMD by element arithmetic on page C3-175.
• SIMD permute on page C3-176.
• SIMD immediate on page C3-176.
• SIMD shift (immediate) on page C3-177.
• SIMD floating-point and integer conversion on page C3-178.
• SIMD reduce (across vector lanes) on page C3-179.
• SIMD pairwise arithmetic on page C3-179.
• SIMD table lookup on page C3-180.
• The Cryptographic Extensions on page C3-180.

For information about the encoding structure of the instructions in this instruction group, see Data processing, SIMD and floating-point on page C4-215.

For information about the floating-point exceptions, see Floating-point exception traps on page D1-1549.

C3.5.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

• Wide:
  — This is indicated by the suffix \( W \). The element width of the destination register and the first source operand is double that of the second source operand.

• Long:
  — This is indicated by the suffix \( L \). The element width of the destination register is double that of both source operands.

• Narrow:
  — This is indicated by the suffix \( N \). The element width of the destination register is half that of both source operands.
Furthermore, each vector form of the instruction is part of a pair, with a second and upper half suffix of 2, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

--- Note ---

This is referred to as a lane set specifier.

### C3.5.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions DUP, INS, and UMOV. However, ARM recommends using the FMOV instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-49 shows the Floating-point move (register) instructions.

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>Floating-point move to or from general-purpose register without conversion</td>
<td>FMOV (general) on page C7-1006</td>
</tr>
</tbody>
</table>

### C3.5.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a single-precision or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with 0x followed by a hexadecimal representation of the IEEE 754 single-precision or double-precision encoding. ARM recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

The floating-point value must be expressible as $(\pm n/16 \times 2^r)$, where $n$ is an integer in the range $16 \leq n \leq 31$ and $r$ is an integer in the range $-3 \leq r \leq 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

--- Note ---

This encoding does not include the floating-point constant 0.0. There are several instructions that can store zero in a SIMD and floating-point register, but ARM recommends that software uses FMOV Sd, WZR or FMOV Dd, XZR to provide consistency across a range of microarchitectures.

Table C3-50 shows the Floating-point move (immediate) instruction:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FMOV</td>
<td>Floating-point move immediate</td>
<td>FMOV (scalar, immediate) on page C7-1009</td>
</tr>
</tbody>
</table>
C3.5.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- Convert floating-point precision.
- Convert between floating-point and integer or fixed-point.

Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-51 shows the Floating-point precision conversion instruction.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FCVT</td>
<td>Floating-point convert precision (scalar)</td>
<td>FCVT on page C7-904</td>
</tr>
</tbody>
</table>

Convert between floating-point and integer or fixed-point

These instructions convert a floating-point scalar in a SIMD and floating-point register to or from a signed or unsigned integer or fixed-point in a general-purpose register. For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and fbits indicates the number of bits after the binary point. fbits is in the range 1-32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

These instructions generate the Invalid Operation exception, in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out-of-range integer or fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input generates an Inexact exception. When flush-to-zero mode is enabled, zero replaces a denormal input and generates an Input Denormal exception.

Table C3-52 shows the Floating-point and fixed-point conversion instructions.

<table>
<thead>
<tr>

</tr>
<tr>
<td>FCVTPS</td>
<td>Floating-point scalar convert to signed integer, rounding toward positive infinity (scalar form)</td>
<td>FCVTPS (scalar) on page C7-934</td>
</tr>
</tbody>
</table>
The Floating-point round to integral instructions round a floating-point value to an integral floating-point value of the same size.

These instructions generate the Invalid Operation exception in response to a signaling NaN input, or the Input Denormal exception in response to a denormal input when flush-to-zero mode is enabled. The FRINTX instruction can also generate the Inexact exception if the result is numeric and does not have the same numerical value as the input. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as in normal floating-point arithmetic.

Table C3-53 shows the Floating-point round to integral instructions.

<td>Floating-point scalar subtract</td>
<td>FSUB (scalar) on page C7-1057</td>
</tr>
</tbody>
</table>

C3.5.9 Floating-point minimum and maximum

The \( \min(x, y) \) and \( \max(x, y) \) operations return a quiet NaN when either \( x \) or \( y \) is NaN. In flush-to-zero mode subnormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both \( x \) and \( y \) are zero, or subnormal values flushed to zero, with different signs, then +0.0 is returned by \( \max() \) and -0.0 by \( \min() \).

The \( \min\text{Num}(x, y) \) and \( \max\text{Num}(x, y) \) operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN the result is then identical to \( \min(x, y) \) and \( \max(x, y) \).
Table C3-57 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

</tbody>
</table>

C3.5.10   Floating-point comparison

These instructions set the NZCV condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are unordered, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

**Note**
The NZCV flags in the FPSR are associated with AArch32 state. The A64 floating-point comparison instructions do not change the condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

The quiet compare instructions generate an Invalid Operation exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation exception if either of the source operands is any type of NaN.

Table C3-58 shows the Floating-point comparison instructions.

C.5.14 SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

Note
Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-62 shows that SIMD compare instructions.

C3.5.21 SIMD floating-point and integer conversion

The SIMD floating-point and integer conversion instructions generate the Invalid Operation exception in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out-of-range integer or a fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input raises the Inexact exception.

Table C3-69 shows the SIMD floating-point and integer conversion instructions.

C3 A64 Instruction Set Overview
C3.5 Data processing - SIMD and floating-point
Chapter C4
A64 Instruction Set Encoding

This chapter describes the A64 instruction set encoding. It contains an encoding index followed by a set of functional groups. Each group contains an alphabetical list of instructions that have similar function within the instruction set.

It contains the following sections:

• A64 instruction index by encoding on page C4-184.
• Branches, exception generating and system instructions on page C4-185.
• Loads and stores on page C4-188.
• Data processing - immediate on page C4-205.
• Data processing - register on page C4-208.
• Data processing, SIMD and floating-point on page C4-215.

C4.2 Branches, exception generating and system instructions

This section describes the encoding of the instruction classes in the Branch, exception generation and system instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see Branches, Exception generating, and System instructions on page C3-136.

C4.3 Loads and stores

This section describes the encoding of the instruction classes in the Loads and stores instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see Loads and stores on page C3-140.

Table C4-3 Encoding table for the Loads and Stores functional group

C4.4 Data processing - immediate

This section describes the encoding of the instruction classes in the Data processing (immediate) instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see Data processing - immediate on page C3-151.

Table C4-4 Encoding table for the Data Processing - Immediate functional group

C4.5 Data processing - register

This section describes the encoding of the instruction classes in the Data processing (register) instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see Data processing - register on page C3-156.

<table>
<thead>

## C4.6 Data processing, SIMD and floating-point

This section describes the encoding of the instruction classes in the Data processing (SIMD and floating-point) instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see Data processing - SIMD and floating-point on page C3-163.

### Table C4-6 Encoding table for the Data Processing, scalar floating-point and Advanced SIMD functional group

Chapter C5
The A64 System Instruction Class

This chapter describes the A64 system instructions and registers, and the system instruction class encoding space. It contains the following sections:

• About the System instruction and System register descriptions on page C5-242.
• The System instruction class encoding space on page C5-244.
• Special-purpose registers on page C5-264.
• A64 system instructions for cache maintenance on page C5-315.
• A64 system instructions for address translation on page C5-331.
• A64 system instructions for TLB maintenance on page C5-344.
C5.1 About the System instruction and System register descriptions

This section provides general information about the System instructions and the System register descriptions.

The terms defined in Fixed values in instruction and System register descriptions apply throughout this manual. That is, they are not restricted to the System instruction and the System register descriptions.

C5.1.1 Fixed values in instruction and System register descriptions

This section summarizes the terms used to describe fixed values in register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ
Read-As-Zero. See Read-As-Zero (RAZ).
In diagrams, a RAZ bit can be shown as 0.

(0), RES0
Reserved, Should-Be-Zero (SBZ) or RES0.
In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction executes as if the value of the bit was 0.
• Any destination registers of the instruction become UNKNOWN.
This notation can be expanded for bitfields, so a three-bit field can be shown as either (0)(0)(0) or as (000).
In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

The (0) and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

RAO
Read-As-One. See Read-As-One (RAO).
In diagrams, a RAO bit can be shown as 1.

(1), RES1
Reserved, Should-Be-One (SBO) or RES1.
In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates a SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction executes as if the value of the bit was 1.
• Any destination registers of the instruction become UNKNOWN.
This notation can be expanded for bitfields, so a three-bit field can be shown as either (1)(1)(1) or as (111).
In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of RES1 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES1 fields,
The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.
C5.2 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the system register space. These instructions provide:

- Access to System registers, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the CLREX instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

Note

In AArch32 state this functionality is provided through conceptual coprocessors CP14 and CP15, and in part through CP10 and CP11. These are accessed through a generic coprocessor interface. In ARMv8:

- AArch32 state retains this conceptual coprocessor model, and adds register and operation aliases, to simplify access to this functionality.
- In the instruction encoding descriptions, AArch64 state retains the naming of the instruction arguments as Op1, CRn, CRm, and Op2. However, there is no functional distinction between the Opn arguments and the CRx arguments.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview on page C5-245 then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy:

- Op0==0b00, architectural hints, barriers and CLREX, and PSTATE access on page C5-246.
- Op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-249.
- Op0==0b10, Moves to and from debug and trace System registers on page C5-253.
- Op0==0b11, Moves to and from non-debug System registers and Special-purpose registers on page C5-255.
- Reserved control space for IMPLEMENTATION DEFINED functionality on page C5-263.

C5.2.1 Principles of the System instruction class encoding

In ARMv8, an encoding in the System instruction space is identified by a set of arguments, \{ Op0, Op1, CRn, CRm, Op2 \}. These form an encoding hierarchy, where:

Op0

Defines the top-level division of the encoding space, see System instruction class encoding overview on page C5-245.

Op1

Identifies the lowest Exception level at which the encoding is accessible, as follows:

- Accessible at EL0
- Accessible at EL1
- Accessible at EL2
- Accessible at EL3

ARM strongly recommends that implementers adopt this use of Op1 when using the IMPLEMENTATION DEFINED regions of the encoding space described in Reserved control space for IMPLEMENTATION DEFINED functionality on page C5-263.
C5.2.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 16 15</th>
<th>12</th>
<th>11 8 7 5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 1 0 0</td>
<td>L</td>
<td>Op0</td>
<td>Op1</td>
<td>CRn</td>
<td>CRm</td>
<td>Op2</td>
</tr>
</tbody>
</table>

The value of L indicates the transfer direction:

- 0 Transfer to system register.
- 1 Transfer from system register.

The Op0 field is the top level encoding of the System instruction type. Its possible values are:

0b00 These encodings provide:

- Instructions with an immediate field for accessing PSTATE, the current PE state.
- The architectural hint instructions.
- Barriers and the CLREX instruction.

For more information about these encodings, see Op0==0b00, architectural hints, barriers and CLREX, and PSTATE access on page C5-246.

0b01 These encodings provide the cache maintenance, TLB maintenance, and address translation instructions.

--- Note ---

These are equivalent to operations in the AArch32 CP15 space.

---

For more information, see Op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-249.

0b10 These encodings provide moves to and from:

- Legacy AArch32 System registers for execution environments, to provide access to these registers from higher exception levels that are using AArch64.
- Debug and trace registers.

--- Note ---

These are equivalent to the registers in the AArch32 CP14 space.

---

For more information, see Op0==0b10, Moves to and from debug and trace System registers on page C5-253.

0b11 These encodings provide:

- Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.

--- Note ---

The accessed registers are equivalent to the registers in the AArch32 CP15 space.

---

- Access to Special-purpose registers.

For more information, see Instructions for accessing Special-purpose registers on page C5-261 and Instructions for accessing non-debug System registers on page C5-255.
UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.
- All encodings with \( L=1 \) and \( Op0=0b0x \) are UNDEFINED, except for encodings in the area reserved for IMPLEMENTATION DEFINED use, see Reserved control space for IMPLEMENTATION DEFINED functionality on page C5-263.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with \( L=0 \) is UNDEFINED.
- Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with \( L=1 \) is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in Principles of the System instruction class encoding on page C5-244.

C5.2.3 \( Op0==0b00 \), architectural hints, barriers and CLREX, and PSTATE access

The different groups of System register instructions with \( Op0==0b00 \):

- Are identified by the value of \( Crn \).
- Are always encoded with a value of \( 0b11111 \) in the \( Rt \) field.

The encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18</th>
<th>16 15</th>
<th>12 11</th>
<th>8 7 5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 1 0 0</td>
<td>0 0</td>
<td>0</td>
<td>CRn</td>
<td>CRm</td>
<td>Op2</td>
<td>1 1 1 1</td>
<td></td>
</tr>
</tbody>
</table>

The encoding of the \( Crn \) field is as follows:

- \( 0b0010 \) See Architectural hint instructions.
- \( 0b0011 \) See Barriers and CLREX on page C5-247.
- \( 0b0100 \) See Instructions for accessing the PSTATE fields on page C5-248.

Architectural hint instructions

Within the \( Op0==0b00 \) encodings, the architectural hint instructions are identified by \( Crn \) having the value \( 0b0010 \). The encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18</th>
<th>16 15</th>
<th>12 11</th>
<th>5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 1 0 0</td>
<td>0 0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0 1</td>
<td>Op&lt;6:0&gt;</td>
</tr>
</tbody>
</table>

The value of \( Op<6:0> \), formed by concatenating the \( Crn \) and \( Op2 \) fields, determines the hint instruction as follows:

- \( 0b0000000 \) NOP instruction. This has no effect on architectural state other than to advance the PC.
- \( 0b0000001 \) YIELD instruction.
- \( 0b0000010 \) WFE instruction.
- \( 0b0000011 \) WFI instruction.
- \( 0b0000100 \) SEV instruction.
- \( 0b0000101 \) SEVL instruction.
- \( 0b0000110-0b1111111 \)

Unallocated values. These encodings behave as NOPs.
Note

• Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

• The operation of the A64 instructions for architectural hints are identical to the corresponding A32 and T32 instructions.

For more information about:
• The WFE, WFI, SEV, and SEVL instructions, see Mechanisms for entering a low-power state on page D1-1595.
• The YIELD instruction, see Software control features and EL0 on page B1-67.

Barriers and CLREX

Within the Op0==0b00 encodings, the barriers and CLREX instructions are identified by CRn having the value 0b0011. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>CRm</th>
<th>Op2</th>
<th>0b0011</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSHLD</td>
<td>0001</td>
<td></td>
</tr>
<tr>
<td>OSHST</td>
<td>0010</td>
<td></td>
</tr>
<tr>
<td>OSH</td>
<td>0011</td>
<td></td>
</tr>
<tr>
<td>NSHLD</td>
<td>0101</td>
<td></td>
</tr>
<tr>
<td>NSHST</td>
<td>0110</td>
<td></td>
</tr>
<tr>
<td>NSH</td>
<td>0111</td>
<td></td>
</tr>
<tr>
<td>ISHLD</td>
<td>1001</td>
<td></td>
</tr>
<tr>
<td>ISHST</td>
<td>1010</td>
<td></td>
</tr>
<tr>
<td>ISH</td>
<td>1011</td>
<td></td>
</tr>
<tr>
<td>LD</td>
<td>1101</td>
<td></td>
</tr>
</tbody>
</table>

The value of Op2 determines the instruction, as follows. For the DSB and DMB instructions, CRm controls the instruction options.

0b010 CLREX instruction. The value of CRm is ignored.
0b100 DSB instruction. The value of CRm sets the option type, see Table C5-1.
0b101 DMB instruction. The value of CRm sets the option type, see Table C5-1.
0b110 ISB instruction. The value of CRm is ignored.
0b000, 0b001, 0b111, 0b111 UNDEFINED.

Note

Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

Table C5-1 shows the CRm encodings for the data barrier option types.

<table>
<thead>
<tr>
<th>CRm value</th>
<th>Option, for DMB and DSB</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>OSHLD</td>
<td>Outer Shareable, load</td>
</tr>
<tr>
<td>0010</td>
<td>OSHST</td>
<td>Outer Shareable, store</td>
</tr>
<tr>
<td>0011</td>
<td>OSH</td>
<td>Outer Shareable, all</td>
</tr>
<tr>
<td>0101</td>
<td>NSHLD</td>
<td>Non-shareable, load</td>
</tr>
<tr>
<td>0110</td>
<td>NSHST</td>
<td>Non-shareable, store</td>
</tr>
<tr>
<td>0111</td>
<td>NSH</td>
<td>Non-shareable, all</td>
</tr>
<tr>
<td>1001</td>
<td>ISHLD</td>
<td>Inner Shareable, load</td>
</tr>
<tr>
<td>1010</td>
<td>ISHST</td>
<td>Inner Shareable, store</td>
</tr>
<tr>
<td>1011</td>
<td>ISH</td>
<td>Inner Shareable, all</td>
</tr>
<tr>
<td>1101</td>
<td>LD</td>
<td>Full system, load</td>
</tr>
</tbody>
</table>
The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

For more information about:
• The barrier instructions, see Memory barriers on page B2-87.
• The CLREX instruction, see Synchronization and semaphores on page B2-107.

Instructions for accessing the PSTATE fields

Within the Op0==0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>CRm value</th>
<th>Option, for DMB and DSB</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>ST</td>
<td>Full system, store</td>
</tr>
<tr>
<td>0000, 0100, 1000, 1100</td>
<td>#&lt;imm&gt;</td>
<td>Full system, all</td>
</tr>
<tr>
<td>1111</td>
<td>SY</td>
<td>Full system, all</td>
</tr>
</tbody>
</table>

a. #<imm> is a 4-bit unsigned immediate in the range 0-15, encoded in the CRm field.

Note

The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

Instructions for accessing the PSTATE fields

Within the Op0==0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>CRm value</th>
<th>Option, for DMB and DSB</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>ST</td>
<td>Full system, store</td>
</tr>
<tr>
<td>0000, 0100, 1000, 1100</td>
<td>#&lt;imm&gt;</td>
<td>Full system, all</td>
</tr>
<tr>
<td>1111</td>
<td>SY</td>
<td>Full system, all</td>
</tr>
</tbody>
</table>

a. #<imm> is a 4-bit unsigned immediate in the range 0-15, encoded in the CRm field.

For more information about:
• The barrier instructions, see Memory barriers on page B2-87.
• The CLREX instruction, see Synchronization and semaphores on page B2-107.

Instructions for accessing the PSTATE fields

Within the Op0==0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>CRm value</th>
<th>Option, for DMB and DSB</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>ST</td>
<td>Full system, store</td>
</tr>
<tr>
<td>0000, 0100, 1000, 1100</td>
<td>#&lt;imm&gt;</td>
<td>Full system, all</td>
</tr>
<tr>
<td>1111</td>
<td>SY</td>
<td>Full system, all</td>
</tr>
</tbody>
</table>

a. #<imm> is a 4-bit unsigned immediate in the range 0-15, encoded in the CRm field.

Note

The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

For more information about:
• The barrier instructions, see Memory barriers on page B2-87.
• The CLREX instruction, see Synchronization and semaphores on page B2-107.

Instructions for accessing the PSTATE fields

Within the Op0==0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>CRm value</th>
<th>Option, for DMB and DSB</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>ST</td>
<td>Full system, store</td>
</tr>
<tr>
<td>0000, 0100, 1000, 1100</td>
<td>#&lt;imm&gt;</td>
<td>Full system, all</td>
</tr>
<tr>
<td>1111</td>
<td>SY</td>
<td>Full system, all</td>
</tr>
</tbody>
</table>

a. #<imm> is a 4-bit unsigned immediate in the range 0-15, encoded in the CRm field.
Op2==0b111 Selects the MSR DAIFClr instruction, that clears the specified PSTATE.\{D, A, I, F\} bits to 0.
Op1 must be 0b011.
This instruction is accessible at EL1 or higher, and when the value of the SCTLR_EL1.UMA bit is 1 it is also accessible at EL0.

Imm4 determines which of the PSTATE.\{D, A, I, F\} bits is cleared to 0, as follows:
Imm4<3>: If this bit is set to 1 then the D bit is cleared to 0, otherwise the D bit is not changed.
Imm4<2>: If this bit is set to 1 then the A bit is cleared to 0, otherwise the A bit is not changed.
Imm4<1>: If this bit is set to 1 then the I bit is cleared to 0, otherwise the I bit is not changed.
Imm4<0>: If this bit is set to 1 then the F bit is cleared to 0, otherwise the F bit is not changed.

All other combinations of Op1 and Op2 are reserved, and the corresponding instructions are UNDEFINED.

--- Note ---
For PSTATE updates, instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

Writes to PSTATE.\{D, A, I, F\} occur in program order without the need for additional synchronization. Changing PSTATE.SPSel to use EL0 synchronizes any updates to SP_EL0 that have been written by an MSR to SP_EL0, without the need for additional synchronization.

C5.2.4 Op0==0b01, cache maintenance, TLB maintenance, and address translation instructions

The System instructions are encoded with Op0==0b01. The different groups of System instructions are identified by the values of CRn and CRm, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>CRn</th>
<th>CRm</th>
<th>Op1</th>
<th>CRn</th>
<th>CRm</th>
<th>Op2</th>
<th>Xt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The grouping of these instructions depending on the CRn and CRm fields is as follows:

CRn==7
CRm==\{1, 5\} Instruction cache maintenance instructions.
CRm==4 Data cache zero operation.
CRm==\{6, 10, 11, 14\} Data cache maintenance instructions.

See Cache maintenance instructions, and data cache zero on page C5-250.

CRm==8

See Address translation instructions on page C5-251.

CRm==\{11, 15\} See Reserved control space for IMPLEMENTATION DEFINED functionality on page C5-263.
Cache maintenance instructions, and data cache zero

Table C5-2 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111.

Table C5-2 Cache maintenance instructions

<table>
<thead>
<tr>
<th>Instruction</th>

<td></td>
</tr>
<tr>
<td>Data cache zero operation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DC ZVA, Xt</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

For more information about these instructions, see Overview of the cache maintenance instructions on page D3-1696 and Cache maintenance instructions on page D3-1700.
Address translation instructions

Table C5-3 lists the Address translation instructions and their encodings. The syntax of the instructions includes $X_t$, that provides the address to be translated.

Table C5-3 Address translation instructions

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Access instruction encoding</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AT S1E1R, $X_t$</td>

</tr>
</tbody>
</table>

For more information about these instructions, see *Address translation instructions* on page D4-1775.
## TLB maintenance instructions

Table C5-4 lists the TLB maintenance instructions and their encodings. Instructions that take an argument include \(X_t\) in the instruction syntax. For instructions that do not take an argument, the \(X_t\) field is encoded as \(0b11111\).

### Table C5-4 TLB maintenance instructions

</tbody>
</table>
C5.2.5 Op0==0b10, Moves to and from debug and trace System registers

The instructions that move data to and from the debug, Execution environment, and trace system registers are encoded with Op0==0b10. This means the encoding of these instructions is:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Access instruction encoding</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLBI ALLE3IS</td>
<td>1 6 8 3 0</td>
<td>Accessible only from EL3.</td>
</tr>
<tr>
<td>TLBI VAES, xt</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>TLBI VAES, xt</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>TLBI ALE3</td>
<td>7 0</td>
<td></td>
</tr>
<tr>
<td>TLBI VAES, xt</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>TLBI VAES, xt</td>
<td>5</td>
<td></td>
</tr>
</tbody>
</table>

For more information about these instructions, see TLB maintenance instructions on page D4-1830.

Note

These encodings access the registers that are equivalent to the AArch32 CP14 registers.

The value of Op1 provides the next level of decode of these instructions, as follows:

- **Op1 == {0, 3, 4}**
  
  Debug. See Instructions for accessing debug System registers

- **Op1 == 1**
  
  Trace. See the appropriate trace architecture specification.

Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

- MSR <System register>, Xt ; Write to System register
- MRS Xt, <System register> ; Read from System register

Where <System_register> is the register name, for example MDCCSR_EL0.

This section includes only the System register access encodings for which both:

- Op0 is 0b10.
- The value of Op1 is one of {0, 3, 4}.

Note

These encodings access the registers that are equivalent to the AArch32 CP14 registers.
Table C5-5 shows the mapping of the System register encodings for debug System register access.

<table>
<thead>
<tr>

<td>0</td>
</tr>
</tbody>
</table>

a. Unimplemented breakpoint and watchpoint register access instructions are unallocated. CRm encodes \(<n>\); the breakpoint or watchpoint number.

For more information see *Mapping of the System registers between the Execution states* on page D1-1607.
C5.2.6 Op0==0b11, Moves to and from non-debug System registers and Special-purpose registers

The instructions that move data to and from non-debug system registers are encoded with Op0==0b11, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|----------------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|
| 1 1 0 1 0 1 0 0 | L | 1 1 | Op1 | CRn | CRm | Op2 | Rt |

The value of CRn provides the next level of decode of these instructions, as follows:

CRn=={0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14}  See Instructions for accessing non-debug System registers.

CRn==4  See Instructions for accessing Special-purpose registers on page C5-261.

CRn=={11, 15}  See Reserved control space for IMPLEMENTATION DEFINED functionality on page C5-263.

Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

MSR <System register>, Xt ; Write to System register
MRS Xt, <System register> ; Read from System register

Where <System_register> is the register name, for example MIDR_EL1.

This section includes only the System register access encodings for which both:

• Op0 is 0b11.
• The value of CRn is one of {0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14}.

Note

These encodings access the registers that are equivalent to the AArch32 CP15 registers.

The instruction encoding for these accesses is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|----------------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|
| 1 1 0 1 0 1 0 0 | L | 1 1 | Op1 | CRn | CRm | Op2 | Rt |

See text for permitted values of CRn.
Table C5-6 shows the encodings of the register access instructions.

Performance Monitors registers, AArch64 view
Instructions for accessing Special-purpose registers

The A64 instructions for accessing Special-purpose registers are:

MSR <Special-purpose register>, Xt ; Write to Special-purpose register
MRS Xt, <Special-purpose register> ; Read from Special-purpose register

For these accesses, CRn has the value 4. The encoding for Special-purpose register accesses is:

```
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | L | 1 | 1 | Op1 | 0 | 1 | 0 | CRm | Op2 | Rt |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
```

</tbody>
</table>

All direct and indirect reads and writes to these registers appear to occur in program order relative to other instructions.
### C5.2.7 Reserved control space for IMPLEMENTATION DEFINED functionality

The A64 instruction set reserves the following space for IMPLEMENTATION DEFINED instructions:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 16 | 15 | 12 | 11 | 5 | 4 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | L  | 0  | 1  |

| IMPLEMENTATION DEFINED | IMPLEMENTATION DEFINED |

The value of L defines the use of Rt as follows:

- **0**: Rt is an argument supplied to the instruction.
- **1**: Rt is a result returned by the instruction.

The A64 instruction set reserves the following space for IMPLEMENTATION DEFINED registers:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 16 | 15 | 12 | 11 | 5 | 4 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | L  | 1  | 1  |

| IMPLEMENTATION DEFINED | IMPLEMENTATION DEFINED |

The value of L defines the access type and the use of Rt as follows:

- **0**: Write the value in Rt to the IMPLEMENTATION DEFINED register.
- **L==1**: Read the value of the IMPLEMENTATION DEFINED register to Rt.
C5.3 Special-purpose registers

This section describes the following registers:

- CurrentEL, that software can read to determine the current Exception level.
- DAIF, that specifies the current interrupt mask bits.
- DLR_EL0, that holds the address to return to for a return from Debug state.
- DSPSR_EL0, that holds process state on entry to Debug state.
- ELR_EL1, that holds the address to return to for an exception return from EL1.
- ELR_EL2, that holds the address to return to for an exception return from EL2.
- ELR_EL3, that holds the address to return to for an exception return from EL3.
- FPCR, that provides control of floating-point operation.
- FPSR, that provides floating-point status information.
- NZCV, that holds the condition flags.
- SP_EL0, that holds the stack pointer for EL0.
- SP_EL1, that holds the stack pointer for EL1.
- SP_EL2, that holds the stack pointer for EL2.
- SP_EL3, that holds the stack pointer for EL3.
- SPSelect, that at EL1 or higher selects between the SP for the current Exception level and SP_EL0.
- SPSR_abt, that holds process state on taking an exception to AArch32 Abort mode.
- SPSR_EL1, that holds process state on taking an exception to AArch64 EL1.
- SPSR_EL2, that holds process state on taking an exception to AArch64 EL2.
- SPSR_EL3, that holds process state on taking an exception to AArch64 EL3.
- SPSR_fiq, that holds process state on taking an exception to AArch32 FIQ mode.
- SPSR_irq, that holds process state on taking an exception to AArch32 IRQ mode.
- SPSR_und, that holds process state on taking an exception to AArch32 Undefined mode.

The PSRs hold the PE state from immediately before taking the exception or entering Debug state. This means they hold the state required for the return from Debug state, or for the exception return.
C5.3.1 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

Purpose

Holds the current Exception level.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

A write to the CurrentEL register is UNDEFINED.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There are no configuration notes.

Attributes

CurrentEL is a 32-bit register.

Field descriptions

The CurrentEL bit assignments are:

![Field Assignment Diagram]

Bits [31:4]

Reserved, RES0.

EL, bits [3:2]

Current Exception level. Possible values of this field are:

<table>
<thead>
<tr>
<th>EL</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>EL0</td>
</tr>
<tr>
<td>01</td>
<td>EL1</td>
</tr>
<tr>
<td>10</td>
<td>EL2</td>
</tr>
<tr>
<td>11</td>
<td>EL3</td>
</tr>
</tbody>
</table>

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED value, that might be UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the CurrentEL:

To access the CurrentEL:
MRS <Xt>, CurrentEL ; Read CurrentEL into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0100</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
C5.3.2 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

Purpose

Allows access to the interrupt mask bits.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If SCTLR_EL1.UMA==0, EL0 accesses to this register are trapped to EL1.

If SCTLR_EL1.UMA==1, EL0 execution of MRS, MSR(register), or MSR(immediate) instructions that access the DAIF is not trapped to EL1.

Configurations

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

DAIF is a 32-bit register.

Field descriptions

The DAIF bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>D</td>
<td>A</td>
<td>I</td>
<td>F</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

0 Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are not masked.

1 Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are masked.

When the target Exception level of the debug exception is not than the current Exception level, the exception is not masked by this bit.

When this register has an architecturally-defined reset value, this field resets to 1.

A, bit [8]

SError (System Error) mask bit. The possible values of this bit are:

0 Exception not masked.
Exception masked.
When this register has an architecturally-defined reset value, this field resets to 1.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
When this register has an architecturally-defined reset value, this field resets to 1.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
When this register has an architecturally-defined reset value, this field resets to 1.

Bits [5:0]
Reserved, RES0.

Accessing the DAIF:
To access the DAIF:

MRS <Xt>, DAIF ; Read DAIF into Xt
MSR DAIF, <Xt> ; Write Xt to DAIF

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.3  DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register DLR_EL0[31:0] is architecturally mapped to AArch32 System register DLR.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

DLR_EL0 is a member of multiple register groups and is defined elsewhere. For the full definition, see DLR_EL0.

Accessing the DLR_EL0:

To access the DLR_EL0:

MRS <Xt>, DLR_EL0 ; Read DLR_EL0 into Xt
MSR DLR_EL0, <Xt> ; Write Xt to DLR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.4 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved process state on entry to Debug state.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register DSPSR_EL0 is architecturally mapped to AArch32 System register DSPSR.

Attributes

DSPSR_EL0 is a 32-bit register.

Field descriptions

DSPSR_EL0 is a member of multiple register groups and is defined elsewhere. For the full definition, see DSPSR_EL0.

Accessing the DSPSR_EL0:

To access the DSPSR_EL0:

MRS <Xt>, DSPSR_EL0 ; Read DSPSR_EL0 into Xt
MSR DSPSR_EL0, <Xt> ; Write Xt to DSPSR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.5 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

**Purpose**

When taking an exception to EL1, holds the address to return to.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

There are no configuration notes.

**Attributes**

ELR_EL1 is a 64-bit register.

**Field descriptions**

The ELR_EL1 bit assignments are:

![Return address]

Bits [63:0]

Return address.

**Accessing the ELR_EL1:**

To access the ELR_EL1:

MRS <Xt>, ELR_EL1 ; Read ELR_EL1 into Xt
MSR ELR_EL1, <Xt> ; Write Xt to ELR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.6  ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

**Purpose**

When taking an exception to EL2, holds the address to return to.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.

When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register ELR_EL2 is architecturally mapped to AArch32 System register ELR_hyp.

**Attributes**

ELR_EL2 is a 64-bit register.

**Field descriptions**

The ELR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
<th>_</th>
<th>_</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Return address</td>
<td>Return address</td>
</tr>
</tbody>
</table>

**Accessing the ELR_EL2:**

To access the ELR_EL2:

MRS <Xt>, ELR_EL2 ; Read ELR_EL2 into Xt
MSR ELR_EL2, <Xt> ; Write Xt to ELR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.7 ELR_EL3, Exception Link Register (EL3)

The ELR_EL3 characteristics are:

Purpose
When taking an exception to EL3, holds the address to return to.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

An exception return from EL3 using AArch64 makes ELR_EL3 become UNKNOWN.

Traps and Enables
There are no traps or enables affecting this register.

Configurations
There are no configuration notes.

Attributes
ELR_EL3 is a 64-bit register.

Field descriptions
The ELR_EL3 bit assignments are:

```
+----------------+---------+---------+---------+---------+---------+
| 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

| Return address |
| 63 | 0 |
| 63 | 0 |
| 63 | 0 |
| 63 | 0 |

Bits [63:0]
Return address.

Accessing the ELR_EL3:
To access the ELR_EL3:

MRS <Xt>, ELR_EL3 ; Read ELR_EL3 into Xt
MSR ELR_EL3, <Xt> ; Write Xt to ELR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.8 FPCR, Floating-point Control Register

The FPCR characteristics are:

**Purpose**

Controls floating-point behavior.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If CPACR_EL1.FPEN==00, EL0 and EL1 accesses to this register are trapped to EL1.
- If CPACR_EL1.FPEN==01, EL0 accesses to this register are trapped to EL1.
- If CPACR_EL1.FPEN==10, EL0 and EL1 accesses to this register are trapped to EL1.
- If CPACR_EL1.FPEN==11, Does not cause any instruction to be trapped.
- If CPTR_EL2.TFP==1, Non-secure EL0, EL1, and EL2 accesses to this register are trapped to EL2.
- If CPTR_EL3.TFP==1, EL0, EL1, EL2, and EL3 accesses to this register are trapped to EL3.

**Configurations**

The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

FPCR is a 32-bit register.

**Field descriptions**

The FPCR bit assignments are:

| 31 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|
| RES0 | FZ  | Stride | Len | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 |

AHP
DN
RM ode
RES0

**Bits [31:27]**

Reserved, RES0.
AHP, bit [26]  
Alternative half-precision control bit:  
0 IEEE half-precision format selected.  
1 Alternative half-precision format selected.  

DN, bit [25]  
Default NaN mode control bit:  
0 NaN operands propagate through to the output of a floating-point operation.  
1 Any operation involving one or more NaNs returns the Default NaN.  
The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.  

FZ, bit [24]  
Flush-to-zero mode control bit:  
0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.  
1 Flush-to-zero mode enabled.  
The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.  

RMode, bits [23:22]  
Rounding Mode control field. The encoding of this field is:  
00 Round to Nearest (RN) mode  
01 Round towards Plus Infinity (RP) mode  
10 Round towards Minus Infinity (RM) mode  
11 Round towards Zero (RZ) mode.  
The specified rounding mode is used by both scalar and Advanced SIMD floating-point instructions.  

Stride, bits [21:20]  
This field has no function in AArch64, and non-zero values are ignored during AArch64 execution. It is included only for context saving and restoration of AArch32 FPSCR.Stride.  

Bit [19]  
Reserved, RES0.  

Len, bits [18:16]  
This field has no function in AArch64, and non-zero values are ignored during AArch64 execution. It is included only for context saving and restoration of AArch32 FPSCR.Len.  

IDE, bit [15]  
Input Denormal exception trap enable. Possible values are:  
0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IDC bit is set to 1.  
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit. The trap handling software can decide whether to set the FPSR.IDC bit to 1.  
The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic. If the implementation does not support this exception, this bit is RES0.  

Bits [14:13]  
Reserved, RES0.
C5 The A64 System Instruction Class
C5.3 Special-purpose registers

IXE, bit [12]
Inexact exception trap enable. Possible values are:
0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IXC bit is set to 1.
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit. The trap handling software can decide whether to set the FPSR.IXC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RES0.

UFE, bit [11]
Underflow exception trap enable. Possible values are:
0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.UFC bit is set to 1.
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.UFC bit. The trap handling software can decide whether to set the FPSR.UFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RES0.

OFE, bit [10]
Overflow exception trap enable. Possible values are:
0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.OFC bit is set to 1.
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.OFC bit. The trap handling software can decide whether to set the FPSR.OFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RES0.

DZE, bit [9]
Division by Zero exception trap enable. Possible values are:
0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.DZC bit is set to 1.
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.DZC bit. The trap handling software can decide whether to set the FPSR.DZC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RES0.

IOE, bit [8]
Invalid Operation exception trap enable. Possible values are:
0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IOC bit is set to 1.
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IOC bit. The trap handling software can decide whether to set the FPSR.IOC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RES0.
Bits [7:0]

Reserved, RES0.

**Accessing the FPCR:**

To access the FPCR:

MRS <Xt>, FPCR ; Read FPCR into Xt
MSR FPCR, <Xt> ; Write Xt to FPCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0100</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.9  FPSR, Floating-point Status Register

The FPSR characteristics are:

Purpose

Provides floating-point system status information.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If CPACR_EL1.FPEN==00, EL0 and EL1 accesses to this register are trapped to EL1.
If CPACR_EL1.FPEN==01, EL0 accesses to this register are trapped to EL1.
If CPACR_EL1.FPEN==10, EL0 and EL1 accesses to this register are trapped to EL1.
If CPTR_EL2.TFP==1, Non-secure EL0, EL1, and EL2 accesses to this register are trapped to EL2.
If CPTR_EL3.TFP==1, EL0, EL1, EL2, and EL3 accesses to this register are trapped to EL3.
If CPACR_EL1.FPEN==11, Does not cause any instruction to be trapped.

Configurations

The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

FPSR is a 32-bit register.

Field descriptions

The FPSR bit assignments are:

N, bit [31]

Negative condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.N flag instead.
Z, bit [30]
Zero condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.Z flag instead.

C, bit [29]
Carry condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.C flag instead.

V, bit [28]
Overflow condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.V flag instead.

QC, bit [27]
Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

Bits [26:8]
Reserved, RES0.

IDC, bit [7]
Input Denormal cumulative exception bit. This bit is set to 1 to indicate that the Input Denormal exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is only set to 1 to indicate an exception if FPCR.IDE is 0, or if trapping software sets it.

Bits [6:5]
Reserved, RES0.

IXC, bit [4]
Inexact cumulative exception bit. This bit is set to 1 to indicate that the Inexact exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is only set to 1 to indicate an exception if FPCR.IXE is 0, or if trapping software sets it.

UFC, bit [3]
Underflow cumulative exception bit. This bit is set to 1 to indicate that the Underflow exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is only set to 1 to indicate an exception if FPCR.UFE is 0, or if trapping software sets it.

OFC, bit [2]
Overflow cumulative exception bit. This bit is set to 1 to indicate that the Overflow exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is only set to 1 to indicate an exception if FPCR.OFE is 0, or if trapping software sets it.

DZC, bit [1]
Division by Zero cumulative exception bit. This bit is set to 1 to indicate that the Division by Zero exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is only set to 1 to indicate an exception if FPCR.DZE is 0, or if trapping software sets it.
IOC, bit [0]

Invalid Operation cumulative exception bit. This bit is set to 1 to indicate that the Invalid Operation exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IOE bit. This bit is only set to 1 to indicate an exception if FPCR.IOE is 0, or if trapping software sets it.

Accessing the FPSR:

To access the FPSR:

MRS <Xt>, FPSR ; Read FPSR into Xt
MSR FPSR, <Xt> ; Write Xt to FPSR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0100</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.10   NZCV, Condition Flags

The NZCV characteristics are:

**Purpose**

Allows access to the condition flags.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

There are no configuration notes.

**Attributes**

NZCV is a 32-bit register.

**Field descriptions**

The NZCV bit assignments are:

N, bit [31]  
Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative.

Z, bit [30]  
Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]  
Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]  
Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Bits [27:0]  
Reserved, RES0.

**Accessing the NZCV:**

To access the NZCV:

MRS <Xt>, NZCV ; Read NZCV into Xt
MSR NZCV, <Xt> ; Write Xt to NZCV
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.11 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

**Purpose**

Holds the stack pointer if SPSel.SP is 0, or the stack pointer for EL0 if SPSel.SP is 1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is also accessible at EL0 as the current stack pointer, and at any Exception level as the current stack pointer when SPSel.SP is 0.

If SPSel.SP is 0 (the stack pointer selected is SP_EL0) then any access to SP_EL0 using the MSR or MRS instructions is UNDEFINED.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

There are no configuration notes.

**Attributes**

SP_EL0 is a 64-bit register.

**Field descriptions**

The SP_EL0 bit assignments are:

Bits [63:0]

Stack pointer

Accessing the SP_EL0:

To access the SP_EL0:

MRS <Xt>, SP_EL0 ; Read SP_EL0 into Xt
MSR SP_EL0, <Xt> ; Write Xt to SP_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0100</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.12 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

Purpose

Holds the stack pointer for EL1 if SPSel.SP is 1 (the stack pointer selected is SP_ELx).

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is also accessible at EL1 as the current stack pointer when SPSel.SP is 1.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There are no configuration notes.

Attributes

SP_EL1 is a 64-bit register.

Field descriptions

The SP_EL1 bit assignments are:

\[
\begin{array}{c}
\text{63} \\
\text{0}
\end{array}
\]

\begin{itemize}
  \item Stack pointer
\end{itemize}

Bits [63:0]

Stack pointer.

Accessing the SP_EL1:

To access the SP_EL1:

MRS <Xt>, SP_EL1 ; Read SP_EL1 into Xt
MSR SP_EL1, <Xt> ; Write Xt to SP_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0100</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.13  SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

Purpose
Holds the stack pointer for EL2 if SPSel.SP is 1 (the stack pointer selected is SP_ELx).

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is also accessible at EL2 as the current stack pointer when SPSel.SP is 1.

Traps and Enables
There are no traps or enables affecting this register.

Configurations
There are no configuration notes.

Attributes
SP_EL2 is a 64-bit register.

Field descriptions
The SP_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
</tr>
<tr>
<td>Stack pointer</td>
</tr>
</tbody>
</table>

Accessing the SP_EL2:
To access the SP_EL2:

MRS <Xt>, SP_EL2 ; Read SP_EL2 into Xt
MSR SP_EL2, <Xt> ; Write Xt to SP_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0100</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.14 SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

Purpose

Holds the stack pointer for EL3 if SPSel.SP is 1 (the stack pointer selected is SP_ELx).

Usage constraints

This register is only accessible at EL3 as the current stack pointer when SPSel.SP is 1.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There are no configuration notes.

Attributes

SP_EL3 is a 64-bit register.

Field descriptions

The SP_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
</table>
| ![Stack pointer](image)

Bits [63:0]

Stack pointer.
C5.3.15 SPSel, Stack Pointer Select

The SPSel characteristics are:

**Purpose**

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

SPSel is a 32-bit register.

**Field descriptions**

The SPSel bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:1]</th>
<th>SP, bit [0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0.</td>
<td>Stack pointer to use. Possible values of this bit are:</td>
</tr>
<tr>
<td>0</td>
<td>Use SP_EL0 at all Exception levels.</td>
</tr>
<tr>
<td>1</td>
<td>Use SP_ELx for Exception level ELx.</td>
</tr>
</tbody>
</table>

When this register has an architecturally-defined reset value, this field resets to 1.

**Accessing the SPSel:**

To access the SPSel:

MRS <Xt>, SPSel ; Read SPSel into Xt
MSR SPSel, <Xt> ; Write Xt to SPSel

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0100</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.16  SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved process state when an exception is taken to Abort mode.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td></td>

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register SPSR_abt is architecturally mapped to AArch32 System register SPSR_abt.

If EL1 does not support execution in AArch32, this register is RES0.

Attributes

SPSR_abt is a 32-bit register.

Field descriptions

The SPSR_abt bit assignments are:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 2 1 0 |
|-------------------|-------------------|-------------------|-------------------|-------------------|
|ansen exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode. |

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.
### IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

### J, bit [24]
RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

### Bits [23:21]
Reserved, RES0.

### IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

### GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

### IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is \texttt{0b00000000} when no IT block is active.

### E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

### A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
- 0 Exception not masked.
- 1 Exception masked.

### I, bit [7]
IRQ mask bit. The possible values of this bit are:
- 0 Exception not masked.
- 1 Exception masked.
F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]
T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]
Execution state that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]
AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

**Accessing the SPSR_abt:**
To access the SPSR_abt:
MRS <Xt>, SPSR_abt ; Read SPSR_abt into Xt
MSR SPSR_abt, <Xt> ; Write Xt to SPSR_abt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0100</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.3.17  **SPSR_EL1, Saved Program Status Register (EL1)**

The SPSR_EL1 characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SPSR_EL1 is architecturally mapped to AArch32 System register SPSR_svc.

**Attributes**

SPSR_EL1 is a 32-bit register.

**Field descriptions**

The SPSR_EL1 bit assignments are:

*When exception taken from AArch32:*

| 31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 0 |
|-------------------------|-------------------------|------------------------|-------------------|-------------------|-------------------|
| N Z C V Q J SS IL GE IT[7:2] E A I F T M[3:0] |
| IT[1:0] | RES0 | M[4] |

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.
Q, bit [27]
Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some
instructions.

IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this
field.

J, bit [24]
RES0.
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.
ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction
set state.

Bits [23:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was
taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in
two parts.
• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the
condition code specified by the first condition field of the IT instruction.
• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be
conditionally executed, by the position of the least significant 1 in this field. It also encodes
the value of the least significant bit of the condition code for each instruction in the block.
The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.
Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also
applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide
Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception
return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to
any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]
T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]
Execution state that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]
AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

When exception taken from AArch64:

<table>
<thead>
<tr>
<th>31 30 29 28 27</th>
<th>22 21 20 19</th>
<th>10 9 8 7 6 5 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>N   Z   C   V</td>
<td>RES0</td>
<td>SS IL</td>
</tr>
<tr>
<td>RES0</td>
<td>D   A   I   F</td>
<td>M[3:0]</td>
</tr>
</tbody>
</table>

M[4] RES0
N, bit [31]
Set to the value of the N condition flag on taking an exception to EL1, and copied to the N condition flag on executing an exception return operation in EL1.

Z, bit [30]
Set to the value of the Z condition flag on taking an exception to EL1, and copied to the Z condition flag on executing an exception return operation in EL1.

C, bit [29]
Set to the value of the C condition flag on taking an exception to EL1, and copied to the C condition flag on executing an exception return operation in EL1.

V, bit [28]
Set to the value of the V condition flag on taking an exception to EL1, and copied to the V condition flag on executing an exception return operation in EL1.

Bits [27:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]
Reserved, RES0.

D, bit [9]
Process state D mask. The possible values of this bit are:
0 Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are not masked.
1 Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are masked.

When the target Exception level of the debug exception is not than the current Exception level, the exception is not masked by this bit.

A, bit [8]
SError (System Error) mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

Bit [5]
Reserved, RES0.
M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

0 Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EL0t</td>
</tr>
<tr>
<td>0010</td>
<td>EL1t</td>
</tr>
<tr>
<td>0011</td>
<td>EL1h</td>
</tr>
</tbody>
</table>

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

• M[3:2] holds the Exception Level.
• M[1] is unused and is RES0 for all non-reserved values.
• M[0] is used to select the SP:
  — 0 means the SP is always SP0.
  — 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL1:

To access the SPSR_EL1:

MRS <Xt>, SPSR_EL1 ; Read SPSR_EL1 into Xt
MSR SPSR_EL1, <Xt> ; Write Xt to SPSR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0100</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.18 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL2.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register SPSR_EL2 is architecturally mapped to AArch32 System register SPSR_hyp.

Attributes

SPSR_EL2 is a 32-bit register.

Field descriptions

The SPSR_EL2 bit assignments are:

When exception taken from AArch32:

N, bit [31]

Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.
Q, bit [27]
Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.

• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:

0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.
1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

*When exception taken from AArch64:*

<table>
<thead>
<tr>
<th>31 30 29 28 27</th>
<th>22 21 20 19</th>
<th>10 9 8 7 6 5 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Z</td>
<td>C</td>
</tr>
</tbody>
</table>

| M[4] | RES0 |

1. Exception masked.
N, bit [31]
Set to the value of the N condition flag on taking an exception to EL2, and copied to the N condition flag on executing an exception return operation in EL2.

Z, bit [30]
Set to the value of the Z condition flag on taking an exception to EL2, and copied to the Z condition flag on executing an exception return operation in EL2.

C, bit [29]
Set to the value of the C condition flag on taking an exception to EL2, and copied to the C condition flag on executing an exception return operation in EL2.

V, bit [28]
Set to the value of the V condition flag on taking an exception to EL2, and copied to the V condition flag on executing an exception return operation in EL2.

Bits [27:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]
Reserved, RES0.

D, bit [9]
Process state D mask. The possible values of this bit are:
0 Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are not masked.
1 Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are masked.

When the target Exception level of the debug exception is not than the current Exception level, the exception is not masked by this bit.

A, bit [8]
SError (System Error) mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

Bit [5]
Reserved, RES0.
M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

0  Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EL0t</td>
</tr>
<tr>
<td>0010</td>
<td>EL1t</td>
</tr>
<tr>
<td>0011</td>
<td>EL1h</td>
</tr>
<tr>
<td>0100</td>
<td>EL2t</td>
</tr>
<tr>
<td>0101</td>
<td>EL2h</td>
</tr>
</tbody>
</table>

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

• M[3:2] holds the Exception Level.
• M[1] is unused and is RES0 for all non-reserved values.
• M[0] is used to select the SP:
  — 0 means the SP is always SP0.
  — 1 means the exception SP is determined by the EL.

**Accessing the SPSR_EL2:**

To access the SPSR_EL2:

MRS <Xt>, SPSR_EL2 ; Read SPSR_EL2 into Xt
MSR SPSR_EL2, <Xt> ; Write Xt to SPSR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0100</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.19 SPSR_EL3, Saved Program Status Register (EL3)

The SPSR_EL3 characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

An exception return from EL3 using AArch64 makes SPSR_EL3 become **UNKNOWN**.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SPSR_EL3 can be mapped to AArch32 System register SPSR_mon, but this is not architecturally mandated.

**Attributes**

SPSR_EL3 is a 32-bit register.

**Field descriptions**

The SPSR_EL3 bit assignments are:

*When exception taken from AArch32:*

N, bit [31]

Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.
Q, bit [27]
Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
RES0.
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

When exception taken from AArch64:

```
N  Z  C  V  RES0  SS  IL  RES0  D  A  I  F  M[3:0]
```

M[4]  

RES0
N, bit [31]
Set to the value of the N condition flag on taking an exception to EL3, and copied to the N condition flag on executing an exception return operation in EL3.

Z, bit [30]
Set to the value of the Z condition flag on taking an exception to EL3, and copied to the Z condition flag on executing an exception return operation in EL3.

C, bit [29]
Set to the value of the C condition flag on taking an exception to EL3, and copied to the C condition flag on executing an exception return operation in EL3.

V, bit [28]
Set to the value of the V condition flag on taking an exception to EL3, and copied to the V condition flag on executing an exception return operation in EL3.

Bits [27:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]
Reserved, RES0.

D, bit [9]
Process state D mask. The possible values of this bit are:
0  Debug exceptions from Watchpoint, Breakpoint, and Software step debug events
targeted at the current Exception level are not masked.
1  Debug exceptions from Watchpoint, Breakpoint, and Software step debug events
   targeted at the current Exception level are masked.

When the target Exception level of the debug exception is not than the current Exception level, the
exception is not masked by this bit.

A, bit [8]
SError (System Error) mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.

Bit [5]
Reserved, RES0.
M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

0 Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>EL0t</td>
</tr>
<tr>
<td>0b0100</td>
<td>EL1t</td>
</tr>
<tr>
<td>0b0101</td>
<td>EL1h</td>
</tr>
<tr>
<td>0b1000</td>
<td>EL2t</td>
</tr>
<tr>
<td>0b1001</td>
<td>EL2h</td>
</tr>
<tr>
<td>0b1100</td>
<td>EL3t</td>
</tr>
<tr>
<td>0b1101</td>
<td>EL3h</td>
</tr>
</tbody>
</table>

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

• M[3:2] holds the Exception Level.
• M[1] is unused and is RES0 for all non-reserved values.
• M[0] is used to select the SP:
  — 0 means the SP is always SP0.
  — 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL3:

To access the SPSR_EL3:

MRS <Xt>, SPSR_EL3 ; Read SPSR_EL3 into Xt
MSR SPSR_EL3, <Xt> ; Write Xt to SPSR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0100</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.3.20   **SPSR_fiq, Saved Program Status Register (FIQ mode)**

The SPSR_fiq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to FIQ mode.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SPSR_fiq is architecturally mapped to AArch32 System register SPSR_fiq.

If EL1 does not support execution in AArch32, this register is RES0.

**Attributes**

SPSR_fiq is a 32-bit register.

**Field descriptions**

The SPSR_fiq bit assignments are:

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 0
```

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

**Q, bit [27]**

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.
IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
RES0.
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]
Reserved, RES0.

IL., bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.
The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.
Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
F, bit [6]

FIQ mask bit. The possible values of this bit are:
0       Exception not masked.
1       Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was
taken from. Possible values of this bit are:
0       Taken from A32 state.
1       Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1       Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SPSR_irq is architecturally mapped to AArch32 System register SPSR_irq.

If EL1 does not support execution in AArch32, this register is RES0.

**Attributes**

SPSR_irq is a 32-bit register.

**Field descriptions**

The SPSR_irq bit assignments are:

```
31 30 29 28 27 26 25 24 23 21 20 19 16 15 10 9 8 7 6 5 4 3 0
```

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

**Q, bit [27]**

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.
IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
RES0.
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]
Reserved, RES0.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.
Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
F, bit [6]

FIQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Taken from A32 state.
1  Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1  Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>

</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SPSR_und is architecturally mapped to AArch32 System register SPSR_und.

If EL1 does not support execution in AArch32, this register is RES0.

**Attributes**

SPSR_und is a 32-bit register.

**Field descriptions**

The SPSR_und bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.

**Q, bit [27]**

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.
C5 The A64 System Instruction Class
C5.3 Special-purpose registers

IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
RES0.
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]
Reserved, RES0.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.
Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
F, bit [6]

FIQ mask bit. The possible values of this bit are:
0   Exception not masked.
1   Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0   Taken from A32 state.
1   Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1   Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>

C5.4 A64 system instructions for cache maintenance

The following sections define the cache maintenance system instructions in A64:

- DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way on page C5-316.
- DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC on page C5-318.
- DC CSW, Data or unified Cache line Clean by Set/Way on page C5-319.
- DC CVAC, Data or unified Cache line Clean by VA to PoC on page C5-321.
- DC CVAU, Data or unified Cache line Clean by VA to PoU on page C5-322.
- DC ISW, Data or unified Cache line Invalidate by Set/Way on page C5-323.
- DC IVAC, Data or unified Cache line Invalidate by VA to PoC on page C5-325.
- DC ZVA, Data Cache Zero by VA on page C5-326.
- IC IALLU, Instruction Cache Invalidate All to PoU on page C5-328.
- IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable on page C5-329.
- IC IVAU, Instruction Cache line Invalidate by VA to PoU on page C5-330.
C5.4.1 DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way

The DC CISW characteristics are:

**Purpose**

Clean and Invalidate data cache by set/way.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization](#D1-1546). Subject to the prioritization rules:

If HCR_EL2.TSW==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

AArch64 System operation DC CISW performs the same function as AArch32 System operation DCCISW.

**Attributes**

DC CISW is a 64-bit system operation.

**Field descriptions**

The DC CISW input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>RES0</td>
</tr>
<tr>
<td>32-31</td>
<td>SetWay</td>
</tr>
<tr>
<td>4-0</td>
<td>Level</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.
Bits[L-1:4] are RES0.

A = \log_2(\text{ASSOCIATIVITY}), L = \log_2(\text{LINELEN}), B = (L + S), S = \log_2(\text{NSETS}).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Performing the DC CISW operation:**

To perform the DC CISW operation:

```
DC CISW, <Xt>
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>0111</td>
<td>1110</td>
<td>010</td>
</tr>
</tbody>
</table>
C5.4.2 DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC

The DC CIVAC characteristics are:

**Purpose**

Clean and Invalidate data cache by address to Point of Coherency.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TPC==1, Non-secure EL0 execution of this instruction is trapped to EL2.
- If SCTLR_EL1.UCI==0, EL0 execution of this instruction is trapped to EL1.

**Configurations**

AArch64 System operation DC CIVAC performs the same function as AArch32 System operation DCCIMVAC.

**Attributes**

DC CIVAC is a 64-bit system operation.

**Field descriptions**

The DC CIVAC input value bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Virtual address to use</td>
</tr>
<tr>
<td>0</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>
```

**Performing the DC CIVAC operation:**

To perform the DC CIVAC operation:

```
DC CIVAC, <x>
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>011</td>
<td>0111</td>
<td>1110</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.4.3 DC CSW, Data or unified Cache line Clean by Set/Way

The DC CSW characteristics are:

**Purpose**

Clean data cache by set/way.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

If HCR_EL2.TSW==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

AArch64 System operation DC CSW performs the same function as AArch32 System operation DCCSW.

**Attributes**

DC CSW is a 64-bit system operation.

**Field descriptions**

The DC CSW input value bit assignments are:

```
63  32  31  4  3  1  0
RES0 SetWay Level RES0
```

**Bits [63:32]**

Reserved, RES0.

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.
Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Performing the DC CSW operation:**

To perform the DC CSW operation:

DC CSW, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>0111</td>
<td>1010</td>
<td>010</td>
</tr>
</tbody>
</table>
C5.4.4 DC CVAC, Data or unified Cache line Clean by VA to PoC

The DC CVAC characteristics are:

**Purpose**

Clean data cache by address to Point of Coherency.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TPC==1, Non-secure EL0 execution of this instruction is trapped to EL2.
- If SCTLR_EL1.UCI==0, EL0 execution of this instruction is trapped to EL1.

**Configurations**

AArch64 System operation DC CVAC performs the same function as AArch32 System operation DCCMVAC.

**Attributes**

DC CVAC is a 64-bit system operation.

**Field descriptions**

The DC CVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

**Performing the DC CVAC operation:**

To perform the DC CVAC operation:

DC CVAC, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>011</td>
<td>011</td>
<td>1010</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.4.5 DC CVAU, Data or unified Cache line Clean by VA to PoU

The DC CVAU characteristics are:

**Purpose**

Clean data cache by address to Point of Unification.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td></td>
</tr>
</tbody>
</table>

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TPU==1, Non-secure EL0 and EL1 execution of this instruction is trapped to EL2.
- If SCTLR_EL1.UCI==0, EL0 execution of this instruction is trapped to EL1.

**Configurations**

AArch64 System operation DC CVAU performs the same function as AArch32 System operation DCCMV AU.

**Attributes**

DC CVAU is a 64-bit system operation.

**Field descriptions**

The DC CVAU input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

To perform the DC CVAU operation:

DC CVAU, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>011</td>
<td>0111</td>
<td>1011</td>
<td>001</td>
</tr>
</tbody>
</table>
## C5.4.6 DC ISW, Data or unified Cache line Invalidate by Set/Way

The DC ISW characteristics are:

### Purpose

Invalidate data cache by set/way.

### Usage constraints

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

At EL1, this operation must operate as DC CISW if all of the following apply:

- EL2 is implemented.
- The value of HCR_EL2.SWIO is 1 or the value of HCR_EL2.VM is 1.

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TSW==1, Non-secure EL1 execution of this instruction is trapped to EL2.

### Configurations

AArch64 System operation DC ISW performs the same function as AArch32 System operation DCISW.

### Attributes

DC ISW is a 64-bit system operation.

### Field descriptions

The DC ISW input value bit assignments are:

![Diagram of field assignments]

- **Bits [63:32]**
  - Reserved, RES0.
SetWay, bits [31:4]
Contains two fields:
• Way, bits[31:32-A], the number of the way to operate on.
• Set, bits[B-1:L], the number of the set to operate on.
Bits[L-1:4] are RES0.
A = \log_2(\text{ASSOCIATIVITY}), \quad L = \log_2(\text{LINELEN}), \quad B = (L + S), \quad S = \log_2(\text{NSETS}).
\text{ASSOCIATIVITY}, \ \text{LINELEN} (\text{line length, in bytes}), \ \text{and NSETS (number of sets)} \ \text{have their usual meanings and are the values for the cache level being operated on. The values of} \ \text{A and S} \ \text{are rounded up to the next integer.}

Level, bits [3:1]
Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]
Reserved, RES0.

Performing the DC ISW operation:
To perform the DC ISW operation:
\text{DC ISW, } <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>0111</td>
<td>0110</td>
<td>010</td>
</tr>
</tbody>
</table>
C5.4.7 DC IVAC, Data or unified Cache line Invalidate by VA to PoC

The DC IVAC characteristics are:

**Purpose**

Invalidate data cache by address to Point of Coherency.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

This instruction requires write access permission to the VA, otherwise it causes a Permission Fault.

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

At EL1, this instruction must be performed as DC CIVAC if all of the following apply:

- EL2 is implemented.
- HCR_EL2.VM is set to 1.
- SCR_EL3.NS is set to 1 or EL3 is not implemented.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

AArch64 System operation DC IVAC performs the same function as AArch32 System operation DCIMVAC.

**Attributes**

DC IVAC is a 64-bit system operation.

**Field descriptions**

The DC IVAC input value bit assignments are:

![Virtual address to use](image)

**Bits [63:0]**

Virtual address to use.

**Performing the DC IVAC operation:**

To perform the DC IVAC operation:

DC IVAC, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>0111</td>
<td>0110</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.4.8 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

**Purpose**

Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

When UNDEFINED, this instruction always takes the EL1 UNDEFINED exception.

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being zeroed is any type of Device memory, this instruction can give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Will cause a Permission Fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

If HCR_EL2.TDZ==1, Non-secure EL0 and EL1 execution of this instruction is trapped to EL2.

If SCTLR_EL1.DZE==0, EL0 execution of this instruction is trapped to EL1.

**Configurations**

There are no configuration notes.

**Attributes**

DC ZVA is a 64-bit system operation.

**Field descriptions**

The DC ZVA input value bit assignments are:

- **Virtual address to use**

  Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.
Performing the DC ZVA operation:

To perform the DC ZVA operation:

```
DC ZVA, <xt>
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>11</td>
<td>111</td>
<td>100</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.4.9 IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

**Purpose**

Invalidate all instruction caches to Point of Unification.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TPU==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

AArch64 System operation IC IALLU performs the same function as AArch32 System operation ICIALLU.

**Attributes**

IC IALLU is a 64-bit system operation.

**Field descriptions**

The IC IALLU operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the IC IALLU operation:**

To perform the IC IALLU operation:

IC IALLU

The operation is encoded as follows:

```
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>0111</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
```
C5.4.10 IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The IC IALLUIS characteristics are:

**Purpose**

Invalidate all instruction caches in Inner Shareable domain to Point of Unification.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TPU==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

AArch64 System operation IC IALLUIS performs the same function as AArch32 System operation ICIALLUIS.

**Attributes**

IC IALLUIS is a 64-bit system operation.

**Field descriptions**

The IC IALLUIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the IC IALLUIS operation:**

To perform the IC IALLUIS operation:

IC IALLUIS

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

C5.5 A64 system instructions for address translation

The following sections define the address translation system instructions in A64:

- AT S1E0R, Address Translate Stage 1 EL0 Read on page C5-332.
- AT S1E0W, Address Translate Stage 1 EL0 Write on page C5-333.
- AT S1E1R, Address Translate Stage 1 EL1 Read on page C5-334.
- AT S1E1W, Address Translate Stage 1 EL1 Write on page C5-335.
- AT S1E0R, Address Translate Stage 1 EL0 Read on page C5-336.
- AT S1E0W, Address Translate Stage 1 EL0 Write on page C5-337.
- AT S1E1R, Address Translate Stage 1 EL1 Read on page C5-338.
- AT S1E1W, Address Translate Stage 1 EL1 Write on page C5-339.
- AT S1E2R, Address Translate Stage 1 EL2 Read on page C5-340.
- AT S1E2W, Address Translate Stage 1 EL2 Write on page C5-341.
- AT S1E3R, Address Translate Stage 1 EL3 Read on page C5-342.
- AT S1E3W, Address Translate Stage 1 EL3 Write on page C5-343.
C5.5.1  AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for EL0, with permissions as if reading from the given virtual address.

Usage constraints

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td></td>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E0R.

Traps and Enables

There are no traps or enables affecting this operation.

Configurations

There are no configuration notes.

Attributes

AT S12E0R is a 64-bit system operation.

Field descriptions

The AT S12E0R input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Input address for translation

Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S12E0R operation:

To perform the AT S12E0R operation:

AT S12E0R, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>011</td>
<td>1000</td>
<td>110</td>
</tr>
</tbody>
</table>
C5.5.2 AT S12E0W, Address Translate Stages 1 and 2 EL0 Write

The AT S12E0W characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL0, with permissions as if writing to the given virtual address.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E0W.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

AT S12E0W is a 64-bit system operation.

**Field descriptions**

The AT S12E0W input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Performing the AT S12E0W operation:**

To perform the AT S12E0W operation:

AT S12E0W, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>0111</td>
<td>1000</td>
<td>111</td>
</tr>
</tbody>
</table>
C5.5.3 AT S12E1R, Address Translate Stages 1 and 2 EL1 Read

The AT S12E1R characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL1, with permissions as if reading from the given virtual address.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E1R.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

AT S12E1R is a 64-bit system operation.

**Field descriptions**

The AT S12E1R input value bit assignments are:

Input address for translation

Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

**Performing the AT S12E1R operation:**

To perform the AT S12E1R operation:

AT S12E1R, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>0111</td>
<td>1000</td>
<td>100</td>
</tr>
</tbody>
</table>
C5.5.4  AT S12E1W, Address Translate Stages 1 and 2 EL1 Write

The AT S12E1W characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL1, with permissions as if writing to the given virtual address.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E1W.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

AT S12E1W is a 64-bit system operation.

**Field descriptions**

The AT S12E1W input value bit assignments are:

**Bits [63:0]**

Input address for translation. The resulting address can be read from the PAR_EL1.

Input translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

**Performing the AT S12E1W operation:**

To perform the AT S12E1W operation:

AT S12E1W, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>

- TLBI VALE3, TLB Invalidate by VA, Last level, EL3 on page C5-389.
- TLBI VALE3IS, TLB Invalidate by VA, Last level, EL3, Inner Shareable on page C5-391.
- TLBI VMALE1, TLB Invalidate by VMID, All at stage 1, EL1 on page C5-393.
- TLBI VMALE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable on page C5-394.
- TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1 on page C5-395.
- TLBI VMALLS12E1IS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable on page C5-396.

For more information about these instructions see TLB maintenance instructions on page D4-1830. In particular, for the full description of the scope of each instruction see Scope of the A64 TLB maintenance instructions on page D4-1833.
C5.6.1 TLBI ALLE1, TLB Invalidate All, EL1

The TLBI ALLE1 characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries.

Usage constraints

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see ALL on page D4-1833.

Traps and Enables

There are no traps or enables affecting this operation.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1 is a 64-bit system operation.

Field descriptions

The TLBI ALLE1 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE1 operation:

To perform the TLBI ALLE1 operation:

TLBI ALLE1

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>1000</td>
<td>0111</td>
<td>100</td>
</tr>
</tbody>
</table>
C5.6.2 TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS characteristics are:

**Purpose**

Invalidate all EL1&0 regime stage 1 and 2 TLB entries on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see ALL on page D4-1833.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI ALLE1IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBI ALLE1IS operation:**

To perform the TLBI ALLE1IS operation:

TLBI ALLE1IS

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.
C5.6.3 TLBI ALLE2, TLB Invalidate All, EL2

The TLBI ALLE2 characteristics are:

**Purpose**

Invalidate all EL2 regime stage 1 TLB entries.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

For details of the scope of this instruction see *ALL on page D4-1833*.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE2 is a 64-bit system operation.

**Field descriptions**

The TLBI ALLE2 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBI ALLE2 operation:**

To perform the TLBI ALLE2 operation:

TLBI ALLE2

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>1000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.6.4 TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable

The TLBI ALLE2IS characteristics are:

**Purpose**

Invalidate all EL2 regime stage 1 TLB entries on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Performing this operation from EL3 is **UNDEFINED** if EL2 does not exist.

For details of the scope of this instruction see *ALL* on page D4-1833.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE2IS is a 64-bit system operation.

**Field descriptions**

The TLBI ALLE2IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBI ALLE2IS operation:**

To perform the TLBI ALLE2IS operation:

TLBI ALLE2IS

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>1000</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.6.5 TLBI ALLE3, TLB Invalidate All, EL3

The TLBI ALLE3 characteristics are:

**Purpose**

Invalidate all EL3 regime stage 1 TLB entries.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

For details of the scope of this instruction see *ALL on page D4-1833*.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE3 is a 64-bit system operation.

**Field descriptions**

The TLBI ALLE3 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBI ALLE3 operation:**

To perform the TLBI ALLE3 operation:

TLBI ALLE3

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>110</td>
<td>1000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.6.6 TLBI ALLE3IS, TLB Invalidate All, EL3, Inner Shareable

The TLBI ALLE3IS characteristics are:

**Purpose**

Invalidate all EL3 regime stage 1 TLB entries on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

For details of the scope of this instruction see *ALL* on page D4-1833.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE3IS is a 64-bit system operation.

**Field descriptions**

The TLBI ALLE3IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBI ALLE3IS operation:**

To perform the TLBI ALLE3IS operation:

TLBI ALLE3IS

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>110</td>
<td>1000</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.6.7 TLBI ASIDE1, TLB Invalidate by ASID, EL1

The TLBI ASIDE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID.

Usage constraints

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see ASID on page D4-1834.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBI ASIDE1 is a 64-bit system operation.

Field descriptions

The TLBI ASIDE1 input value bit assignments are:

```
  63  48  47  0
   |   |   |
   ASID  RES0
```

ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this operation.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:0]

Reserved, RES0.

Performing the TLBI ASIDE1 operation:

To perform the TLBI ASIDE1 operation:

TLBI ASIDE1, <Xt>
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>010</td>
</tr>
</tbody>
</table>
### TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable

The TLBI ASIDE1IS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *ASID* on page D4-1834.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ASIDE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI ASIDE1IS input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td></td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this operation.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

**Bits [47:0]**

Reserved, RES0.

**Performing the TLBI ASIDE1IS operation:**

To perform the TLBI ASIDE1IS operation:

TLBI ASIDE1IS, <Xt>
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>010</td>
</tr>
</tbody>
</table>
C5.6.9 TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID.

For details of the scope of this instruction see IPAS2 on page D4-1835.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2E1 is a 64-bit system operation.

**Field descriptions**

The TLBI IPAS2E1 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>36-35</td>
<td>IPA[47:12]</td>
</tr>
</tbody>
</table>

**Performing the TLBI IPAS2E1 operation:**

To perform the TLBI IPAS2E1 operation:

TLBI IPAS2E1, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>1000</td>
<td>0100</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.6.10 TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI IPAS2E1IS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see IPAS2 on page D4-1835.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2E1IS is a 64-bit system operation.

**Field descriptions**

The TLBI IPAS2E1IS input value bit assignments are:

```
  63  36  35   0
RES0 IPA[47:12] ?

Bits [63:36]
Reserved, RES0.

IPA[47:12], bits [35:0]
Bits[47:12] of the intermediate physical address to match.
```

**Performing the TLBI IPAS2E1IS operation:**

To perform the TLBI IPAS2E1IS operation:

TLBI IPAS2E1IS, <x>
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>100</td>
<td>1000</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.6.11 TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI IPAS2LE1 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID.

For details of the scope of this instruction see IPAS2L on page D4-1835.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If SCR_EL3.NS=0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI IPAS2LE1 is a 64-bit system operation.

**Field descriptions**

The TLBI IPAS2LE1 input value bit assignments are:

![Field Descriptions Diagram](image)

- **RES0**: Reserved, RES0.
- **IPA[47:12]**: Bits [47:12] of the intermediate physical address to match.

**Performing the TLBI IPAS2LE1 operation:**

To perform the TLBI IPAS2LE1 operation:

TLBI IPAS2LE1, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

<td>0100</td>
<td>101</td>
</tr>
</tbody>
</table>
C5.6.12  TLBI IPAS2LE1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI IPAS2LE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see IPAS2L on page D4-1835.

Usage constraints

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Traps and Enables

There are no traps or enables affecting this operation.

Configurations

There are no configuration notes.

Attributes

TLBI IPAS2LE1IS is a 64-bit system operation.

Field descriptions

The TLBI IPAS2LE1IS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:36]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPA[47:12], bits [35:0]</td>
<td>Bits[47:12] of the intermediate physical address to match.</td>
</tr>
</tbody>
</table>

Performing the TLBI IPAS2LE1IS operation:

To perform the TLBI IPAS2LE1IS operation:

TLBI IPAS2LE1IS, <Xt>
The operation is encoded as follows:

<table>
<thead>
<tr>

</tbody>
</table>
C5.6.13 TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *VIA* on page D4-1835.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAAE1 is a 64-bit system operation.

**Field descriptions**

The TLBI VAAE1 input value bit assignments are:

![Field descriptions](image)

Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
Where a 64KB translation granularity is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAAE1 operation:

To perform the TLBI VAAE1 operation:

TLBI VAAE1, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>011</td>
</tr>
</tbody>
</table>
C5.6 A64 system instructions for TLB maintenance

C5.6.14 TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *VIA* on page D4-1835.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAAE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI VAAE1IS input value bit assignments are:

| Bits [63:44] | Reserved, RES0. |
| Bits [55:12] | of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID. |

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits [55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAAE1IS operation:

To perform the TLBI VAAE1IS operation:

TLBI VAAE1IS, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>011</td>
</tr>
</tbody>
</table>
C5.6.15 TLBI VAALE1, TLB Invalidate by VA, All ASID, Last level, EL1

The TLBI VAALE1 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *VAAL on page D4-1835*.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAALE1 is a 64-bit system operation.

**Field descriptions**

The TLBI VAALE1 input value bit assignments are:

```
  63 44 43
RES0 VA[55:12]
```

**Bits [63:44]**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits[1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
Where a 64KB translation granule is being used, bits [3:0] of this field are \texttt{RES0} and ignored when the instruction is executed, because \texttt{VA[15:12]} have no effect on the operation of the instruction.

**Performing the TLBI VAALE1 operation:**

To perform the TLBI VAALE1 operation:

\begin{verbatim}
TLBI VAALE1, <Xt>
\end{verbatim}

The operation is encoded as follows:

\begin{verbatim}
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>111</td>
</tr>
</tbody>
</table>
\end{verbatim}
C5.6.16 TLBI VAALLE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAALLE1IS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID, on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see VAAL on page D4-1835.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAALLE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI VAALLE1IS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:44]</th>
<th>Bits [43:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VA[55:12]</td>
</tr>
</tbody>
</table>

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
• Where a 64KB translation granule is used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAALE1IS operation:

To perform the TLBI VAALE1IS operation:

TLBI VAALE1IS, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>111</td>
</tr>
</tbody>
</table>
C5.6.17 TLBI VAE1, TLB Invalidate by VA, EL1

The TLBI VAE1 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and ASID and the current VMID.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *VA* on page D4-1834.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE1 is a 64-bit system operation.

**Field descriptions**

The TLBI VAE1 input value bit assignments are:

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

**Bits [47:44]**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.
If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Performing the TLBI VAE1 operation:**

To perform the TLBI VAE1 operation:

\[ \text{TLBI VAE1, } <\text{x}> \]

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>001</td>
</tr>
</tbody>
</table>
C5.6.18 TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable

The TLBI VAE1IS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *VA* on page D4-1834.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI VAE1IS input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>RES0</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

**Bits [47:44]**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.
If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Performing the TLBI VAE1IS operation:**

To perform the TLBI VAE1IS operation:

TLBI VAE1IS, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>

<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
### TLBI VAE2, TLB Invalidate by VA, EL2

The TLBI VAE2 characteristics are:

**Purpose**
Invalidate EL2 regime stage 1 TLB entries for the given VA.

**Usage constraints**
This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
</tr>
</tbody>
</table>

Performing this operation from EL3 is **UNDEFINED** if EL2 does not exist.

For details of the scope of this instruction see VI on page D4-1834.

**Traps and Enables**
There are no traps or enables affecting this operation.

**Configurations**
There are no configuration notes.

**Attributes**
TLBI VAE2 is a 64-bit system operation.

**Field descriptions**
The TLBI VAE2 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:44]</td>
<td>Reserved, RES0</td>

</tbody>
</table>
C5.6.20 TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable

The TLBI VAE2IS characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the given VA on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

For details of the scope of this instruction see VA on page D4-1834.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAE2IS is a 64-bit system operation.

**Field descriptions**

The TLBI VAE2IS input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>44</th>
<th>43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:44] Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.
Performing the TLBI VAE2IS operation:

To perform the TLBI VAE2IS operation:

TLBI VAE2IS, <xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>

<tr>
<td>43</td>
<td>VA[55:12]</td>
</tr>
</tbody>
</table>

**Bits [63:44]**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Performing the TLBI VAE3IS operation:**

To perform the TLBI VAE3IS operation:
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>110</td>
<td>1000</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
### TLBI VALE1, TLB Invalidate by VA, Last level, EL1

The TLBI VALE1 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see VAL on page D4-1835.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB=1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VALE1 is a 64-bit system operation.

**Field descriptions**

The TLBI VALE1 input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>RES0</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

**Bits [47:44]**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.
If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE1 operation:

To perform the TLBI VALE1 operation:

TLBI VALE1, <Xt>

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>101</td>
</tr>
</tbody>
</table>
C5.6.24 TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see VAL on page D4-1835.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VALE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI VALE1IS input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>RES0</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

**Bits [47:44]**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.
If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Performing the TLBI VALE1IS operation:**

To perform the TLBI VALE1IS operation:

```
TLBI VALE1IS, <xt>
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>101</td>
</tr>
</tbody>
</table>
C5.6.25 TLBI VALE2, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
</tr>
</tbody>
</table>

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

For details of the scope of this instruction see VAL on page D4-1835.

**Traps and Enables**

There are no traps or enables affecting this operation.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VALE2 is a 64-bit system operation.

**Field descriptions**

The TLBI VALE2 input value bit assignments are:

- **Bits [63:44]**
  - Reserved, RES0.

- **VA[55:12]**, bits [43:0]
  - Bits [55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.
  - If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.
  - The treatment of the low-order bits of this field depends on the translation granule size, as follows:
    - Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
    - Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
    - Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.
Performing the TLBI VALE2 operation:

To perform the TLBI VALE2 operation:

C5.6.26 TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI VALE2IS characteristics are:

**Purpose**
Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA on all PEs in the same Inner Shareable domain.

**Usage constraints**
This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td></td>
<td>WO</td>
<td>WO</td>
<td>-</td>
</tr>
</tbody>
</table>

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

For details of the scope of this instruction see **VAL** on page D4-1835.

**Traps and Enables**
There are no traps or enables affecting this operation.

**Configurations**
There are no configuration notes.

**Attributes**
TLBI VALE2IS is a 64-bit system operation.

### Field descriptions
The TLBI VALE2IS input value bit assignments are:

$$
\begin{array}{cccc}
  & 63 & 44 & 43 & 0 \\
\text{RES0} & \text{VA}[55:12] \\
\end{array}
$$

**Bits [63:44]**
Reserved, RES0.

**VA[55:12], bits [43:0]**
Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.
Performing the TLBI VALE2IS operation:

<td>1000</td>
<td>0011</td>
<td>101</td>
</tr>
</tbody>
</table>
C5.6.29 TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 TLB entries for the current VMID.

Usage constraints

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see VMALL on page D4-1834.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1 is a 64-bit system operation.

Field descriptions

The TLBI VMALLE1 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI VMALLE1 operation:

To perform the TLBI VMALLE1 operation:

TLBI VMALLE1

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
C5.6.30 TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS characteristics are:

**Purpose**

Invalidate all EL1&0 regime stage 1 TLB entries for the current VMID on all PEs in the same Inner Shareable domain.

**Usage constraints**

This operation can be performed at the following exception levels:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the value of SCR_EL3.NS determines whether the instruction invalidates the translations that are associated with Secure address space, or invalidates the translations associated with the Non-secure address space.

For details of the scope of this instruction see *VMALL* on page D4-1834.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TTLB==1, Non-secure EL1 execution of this instruction is trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VMALLE1IS is a 64-bit system operation.

**Field descriptions**

The TLBI VMALLE1IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBI VMALLE1IS operation:**

To perform the TLBI VMALLE1IS operation:

TLBI VMALLE1IS

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

Chapter C6
A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:
• Introduction on page C6-398.
• Register size on page C6-399.
• Use of the PC on page C6-400.
• Use of the stack pointer on page C6-401.
• Condition flags and related instructions on page C6-402.
• Alphabetical list of instructions on page C6-403.
C6.1 Introduction

This chapter provides information on key aspects of the base instructions, and an alphabetic list of instructions from the following functional groups:

- Branch, Exception generation, and system instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

_A64 instruction index by encoding on page C4-184_ provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The base instruction descriptions include:

- _Register size_ on page C6-399.
- _Use of the PC_ on page C6-400.
- _Use of the stack pointer_ on page C6-401.
- _Condition flags and related instructions_ on page C6-402.
C6.2 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise ORR could be performed using a 64-bit ORR and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the ORR instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an ADD, SUB, ADDS, or SUBS instruction and the index register of a Load/Store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See Register names on page C1-122 and Register indexed addressing on page C1-126.
C6.3 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- ADR and ADRP.
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, BL and BLR, that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.

For more details on instructions that can modify the PC, see Branches, Exception generating, and System instructions on page C3-136.
C6.4 Use of the stack pointer

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/Store instructions use the current stack pointer as the base address:
  - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned, that is, it must be aligned to 16 bytes. Misalignment generates a Stack Alignment fault. See Stack pointer alignment checking on page D1-1510 for more information.

- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.

- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.
C6.5 Condition flags and related instructions

The A64 base instructions that use the condition flags as an input are:

- Conditional branch. The conditional branch instruction is B.cond.
- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are ADC, ADCS, SBC, and SBCS, or an architectural alias for these instructions.
- Conditional select with increment, negate, or invert. This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are CSINC, CSINV, and CSNEG.

These instructions also implement:
- Conditional select or move. The condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, CSEL.
- Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include CSET and CSETM.
- Conditional compare. This instruction type sets the condition flags to the result of a comparison if the original condition is true, otherwise it sets the condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers. The conditional compare instructions are CCMP and CMN.

The A64 base instructions that update the condition flags as an output are:

- Flag-setting data processing instructions, such as ADCS, ADDS, ANDS, BICS, SBCS, and SUBS, and the aliases CMN, CMP, and TST.
- Conditional compare instructions such as CMN, CMP.

The flags can be directly accessed for a read/write using the NZCV, Condition Flags on page C5-281.

The A64 base instructions also include conditional branch instructions that do not use the condition flags as an input:

- Compare and branch if a register is zero or nonzero, CBZ and CBNZ.
- Test a single bit in a register and branch if the bit is zero or nonzero, TBZ and TBNZ.
C6.6 Alphabetical list of instructions

This section lists every instruction in the base category of the A64 instruction set. For details of the format used, see *Understanding the A64 instruction descriptions* on page C2-132.
C6.6.1   ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{ADC} \ <Wd>, \ <Wn>, \ <Wm>
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{ADC} \ <Xd>, \ <Xn>, \ <Xm>
\]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{boolean } \text{sub\_op} &= (op == '1'); \\
\text{boolean } \text{setflags} &= (S == '1'); \\
\end{align*}
\]

**Assembler symbols**

- \(<Wd>\) \quad Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) \quad Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) \quad Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) \quad Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) \quad Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) \quad Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

**Operation**

\[
\begin{align*}
\text{bits(data\_size)} \text{ result}; \\
\text{bits(data\_size)} \text{ operand1} &= X[n]; \\
\text{bits(data\_size)} \text{ operand2} &= X[m]; \\
\text{bits(4)} \text{ nzcv}; \\
\text{if } \text{sub\_op} \text{ then} \\
&\quad \text{operand2} = \text{NOT}(\text{operand2}); \\
\text{(result, nzcv)} &= \text{Add\_With\_Carry}(\text{operand1}, \text{operand2}, \text{PSTATE.C}); \\
\text{if } \text{setflags} \text{ then} \\
&\quad \text{PSTATE.}<N,Z,C,V> = \text{nzcv}; \\
X[d] &= \text{result};
\end{align*}
\]
C6.6.2 ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.

### 32-bit variant

Applies when $sf = 0$.

```
ADCS <Wd>, <Wn>, <Wm>
```

### 64-bit variant

Applies when $sf = 1$.

```
ADCS <Xd>, <Xn>, <Xm>
```

#### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
```

#### Assembler symbols

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>`: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>`: Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

#### Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

if sub_op then
    operand2 = NOT(operand2);

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```
### C6.6.3 ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the `<Rm>` register can be a byte, halfword, word, or doubleword.

#### 32-bit variant

Applies when `sf = 0`.

```assembly
ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

#### 64-bit variant

Applies when `sf = 1`.

```assembly
ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

#### Decode for all variants of this encoding

- `integer d = UInt(Rd);`
- `integer n = UInt(Rn);`
- `integer m = UInt(Rm);`
- `integer datasize = if sf == '1' then 64 else 32;`
- `boolean sub_op = (op == '1');`
- `boolean setflags = (S == '1');`
- `ExtendType extend_type = DecodeRegExtend(option);`
- `integer shift = UInt(imm3);`
- `if shift > 4 then ReservedValue();`

#### Assembler symbols

- `<Wd|WSP>` is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` is a width specifier, encoded in the "option" field. It can have the following values:
  - `W` when option = 00x
  - `W` when option = 010
  - `X` when option = x11
  - `W` when option = 10x
  - `W` when option = 110
<m>
Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend>
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- **UXTB** when option = 000
- **UXTH** when option = 001
- **LSL|UXTW** when option = 010
- **UXTX** when option = 011
- **SXTB** when option = 100
- **SXTH** when option = 101
- **SXTW** when option = 110
- **SXTX** when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- **UXTB** when option = 000
- **UXTH** when option = 001
- **UXTW** when option = 010
- **LSL|UXTX** when option = 011
- **SXTB** when option = 100
- **SXTH** when option = 101
- **SXTW** when option = 110
- **SXTX** when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount>
Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```c
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
broadcasts(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;
if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
if d == 31 && !setflags then
```

SP[] = result;
else
  X[d] = result;
C6.6.4 ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP). See the Alias conditions table for details of when each alias is preferred.

32-bit variant
Applies when $sf = 0$.

ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}

64-bit variant
Applies when $sf = 1$.

ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if $sf == '1$' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
bits(datasize) imm;

case shift of
  when '00' imm = ZeroExtend(imm12, datasize);
  when '01' imm = ZeroExtend(imm12 : Zeros(12), datasize);
  when '1x' ReservedValue();

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (to/from SP)</td>
<td>shift == '00' &amp; imm12 == '000000000000' &amp; (Rd == '11111'</td>

</table>

Assembler symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

- LSL #0 when shift = 00
- LSL #12 when shift = 01
- It is reserved when shift = 1x.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = imm;
bits(4) nzcv;
bit carry_in;

if sub_op then

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMN (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

**Assembler symbols**

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn|WSP>\) Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn|SP>\) Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R> Is a width specifier, encoded in the "option" field. It can have the following values:
- W when option = 00x
- W when option = 010
- X when option = x11
- W when option = 10x
- W when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:
- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```plaintext
bits(datasize) result;
b Philosophy = if n == 31 then SP[] else X[n];
b Philosophy operand1 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;
if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';
```

    imm = SignExtend(immhi:immlo, 64);

**Assembler symbols**

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<label> Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

**Operation**

bits(64) base = PC[];

if page then
    base<11:0> = Zeros(12);

X[d] = base + imm;
C6.6.10 ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.

| 31 30 29 28|27 26 25 24|23 | 5 4 | 0 |
|---|---|---|---|---|---|
| immlo | immhi | Rd |

Literal variant

ADR P <Xd>, <label>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
boolean page = (op == '1');
bits(64) imm;

if page then
    imm = SignExtend(immhi:immlo:Zeros(12), 64);
else
    imm = SignExtend(immhi:immlo, 64);
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<label> Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

Operation

```plaintext
bits(64) base = PC[];

if page then
    base<11:0> = Zeros(12);

X[d] = base + imm;
```
C6.6.11 AND (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

32-bit variant

Applies when \( sf = 0 \) && \( N = 0 \).

\[
\text{AND} \ {<Wd|WSP>, <Wn>, #<imm>}
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{AND} \ {<Xd|SP>, <Xn>, #<imm>}
\]

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
  case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;
  end;
bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

\(<Wd|WSP>\) Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<Xd|SP>\) Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<imm>\) Is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;
  case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
```
when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
  PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

if d == 31 && !setflags then
  SP[] = result;
else
  X[d] = result;
C6.6.12 **AND (shifted register)**

Bitwise AND (shifted register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

![Instruction Format](image)

### 32-bit variant

Applies when $sf = 0$.

AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

### 64-bit variant

Applies when $sf = 1$.

AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

#### Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
  when '00' op = LogicalOp_AND; setflags = FALSE;
  when '01' op = LogicalOp_ORR; setflags = FALSE;
  when '10' op = LogicalOp_EOR; setflags = FALSE;
  when '11' op = LogicalOp_AND; setflags = TRUE;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

#### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

case op of
  when LogicalOp_AND result = operand1 AND operand2;
  when LogicalOp_ORR result = operand1 OR operand2;
  when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
  PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
### C6.6.13 ANDS (immediate)

Bitwise AND (immediate), setting flags, performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (immediate). See the Aliases table for details of when each alias is preferred.

#### 32-bit variant

Applies when $sf = 0 \&\& N = 0$.

`ANDS <Wd>, <Wn>, #<imm>`

#### 64-bit variant

Applies when $sf = 1$.

`ANDS <Xd>, <Xn>, #<imm>`

**Decode for all variants of this encoding**

```java
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

### Assembler symbols

\(<Wd>\)  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wn>\)  Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Wm>\)  Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<Xd>\)  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10
- ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

``` assembled
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
if invert then operand2 = NOT(operand2);

case op of
  when LogicalOp_AND result = operand1 AND operand2;
  when LogicalOp_ORR result = operand1 OR operand2;
  when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
  PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```
C6.6.15   ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the ASRV instruction. This means that:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode for this instruction.

### 32-bit variant
Applies when $sf = 0$.

$ASR <Wd>, <Wn>, <Wm>$

is equivalent to

$ASRV <Wd>, <Wn>, <Wm>$

and is always the preferred disassembly.

### 64-bit variant
Applies when $sf = 1$.

$ASR <Xd>, <Xn>, < Xm>$

is equivalent to

$ASRV <Xd>, <Xn>, < Xm>$

and is always the preferred disassembly.

### Assembler symbols

- $<Wd>$: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Wm>$: Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- $<Xd>$: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $< Xm>$: Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of ASRV gives the operational pseudocode for this instruction.
C6.6.16   ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \) \&\& \( imms = 011111 \).

\[
\text{ASR} \ <Wd>, <Wn>, #<shift>
\]

is equivalent to

\[
\text{SBFM} \ <Wd>, <Wn>, #<shift>, #31
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \) \&\& \( N = 1 \) \&\& \( imms = 111111 \).

\[
\text{ASR} \ <Xd>, <Xn>, #<shift>
\]

is equivalent to

\[
\text{SBFM} \ <Xd>, <Xn>, #<shift>, #63
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{shift}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

### Operation

The description of SBFM gives the operational pseudocode for this instruction.
C6.6.17    ASRV

Arithmetic Shift Right Variable shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ASR (register). The alias is always the preferred disassembly.

| 31 30 29 28 27 26 25 24 23 22 21 20 | 16 15 14 13 12 11 10 9 | 5 4 | 0 |
| sf | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 |
| Rm | 0 | 0 | 1 | 0 | 1 | 0 |
| Rn | Rd |

**32-bit variant**

Applies when $sf = 0$.

ASRV $<Wd>$, $<Wn>$, $<Wm>$

**64-bit variant**

Applies when $sf = 1$.

ASRV $<Xd>$, $<Xn>$, $<Xm>$

**Decode for all variants of this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

**Assembler symbols**

- $<Wd>$  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$  Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Wm>$  Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- $<Xd>$  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$  Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Xm>$  Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```
C6.6.18   AT

Address Translate. For more information, see *A64 system instructions for address translation* on page C5-331.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

**System variant**

AT \(<_{\text{at} \_\text{op}}>,<_{\text{Xt}}>\)

is equivalent to

SYS \(#_{\text{op}1},C7,C8,#_{\text{op}2},<_{\text{Xt}}>\)

and is the preferred disassembly when SysOp(op1,'0111','1000',op2) == Sys_AT.

**Assembler symbols**

\(<_{\text{at} \_\text{op}}>\) Is an AT operation name, as listed for the AT system operation group, encoded in the "op1:op2" field. It can have the following values:

- S1E1R when op1 = 000, op2 = 000
- S1E1W when op1 = 000, op2 = 001
- S1E0R when op1 = 000, op2 = 010
- S1E0W when op1 = 000, op2 = 011
- S1E2R when op1 = 100, op2 = 000
- S1E2W when op1 = 100, op2 = 001
- S1E1R when op1 = 100, op2 = 100
- S1E1W when op1 = 100, op2 = 101
- S1E0R when op1 = 100, op2 = 110
- S1E0W when op1 = 100, op2 = 111
- S1E3R when op1 = 110, op2 = 000
- S1E3W when op1 = 110, op2 = 001

\(<_{\text{op}1}>\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

\(<_{\text{op}2}>\) Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

\(<_{\text{Xt}}>> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.6.19   B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

\[
\begin{array}{cccccccccc}
31 & 30 & 29 & 28 & 27 & 26 & 25 & 24 & 23 & 5 & 4 & 3 & 0 \\
0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & \text{imm19} & \text{cond} & 0 & 0
\end{array}
\]

**19-bit signed PC-relative branch offset variant**

B.<cond> <label>

**Decode for this encoding**

bits(64) offset = SignExtend(imm19: '00', 64);
bits(4) condition = cond;

**Assembler symbols**

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

**Operation**

if ConditionHolds(condition) then

   BranchTo(PC[] + offset, BranchType_JMP);

C6.6.20  B

Branch causes an unconditional branch to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

26-bit signed PC-relative branch offset variant

B <label>

Decode for this encoding

BranchType branch_type = if op == '1' then BranchType_CALL else BranchType_JMP;
bits(64) offset = SignExtend(imm26:'00', 64);

Assembler symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

if branch_type == BranchType_CALL then X[30] = PC[] + 4;
BranchTo(PC[] + offset, branch_type);
C6.6.21   BFI

Bitfield Insert copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, leaving other bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

32-bit variant
Applies when sf = 0 && N = 0.
BFI <Wd>, <Wn>, #<lsb>, #<width>
is equivalent to
BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
and is the preferred disassembly when UInt(immr) < UInt(imms).

64-bit variant
Applies when sf = 1 && N = 1.
BFI <Xd>, <Xn>, #<lsb>, #<width>
is equivalent to
BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
and is the preferred disassembly when UInt(immr) < UInt(imms).

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation
The description of BFM gives the operational pseudocode for this instruction.
C6.6.22  BFM

Bitfield Move copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, leaving other bits unchanged.

This instruction is used by the aliases BFI and BFXIL. See the Aliases conditions on page C6-438 table for details of when each alias is preferred.

32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \).

BFM <Wd>, <Wn>, #<immr>, #<imms>

64-bit variant

Applies when \( sf = 1 \) \&\& \( N = 1 \).

BFM <Xd>, <Xn>, #<immr>, #<imms>

**Decode for all variants of this encoding**

[31 30 29 28|27 26 25 24|23 22 21 | 16|15 | 10 | 9 | 5 | 4 | 0 ]

sf opc
01
```

**Register usage**

- **Rd**: destination register
- **Rn**: source register
- **immr**: immediate value for low-order bits
- **imms**: immediate value for high-order bits

**Examples**

- **BFM** <Wd>, <Wn>, #<immr>, #<imms>
- **BFM** <Xd>, <Xn>, #<immr>, #<imms>

**Notes**

- **32-bit variant**: Applies when \( sf = 0 \) \&\& \( N = 0 \).
- **64-bit variant**: Applies when \( sf = 1 \) \&\& \( N = 1 \).

**References**

Assembler symbols

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`: Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`: Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<immr>`: For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
- `<imms>`: For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

```c
bits(datasize) dst = if inzero then Zeros() else X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

// determine extension bits (sign, zero or dest register)
bits(datasize) top = if extend then Replicate(src<S>) else dst;

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```
C6.6.23   BFXIL

Bitfield extract and insert at low end copies any number of low-order bits from a source register into the same number of adjacent bits at the low end in the destination register, leaving other bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf = 0 && N = 0.

BFXIL <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when UInt(imms) >= UInt(immr).

64-bit variant

Applies when sf = 1 && N = 1.

BFXIL <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when UInt(imms) >= UInt(immr).

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.
C6.6.24  BIC (shifted register)

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when $sf = 0$.

BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when $sf = 1$.

BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

```plaintext
d = UInt(Rd);
n = UInt(Rn);
m = UInt(Rm);
datasize = if sf == '1' then 64 else 32;
setflags = false;
op = case opc of
    '00' => LogicalOp_AND;
    '01' => LogicalOp_ORR;
    '10' => LogicalOp_EOR;
    '11' => LogicalOp_AND;
end;
if sf == '0' && imm6<5> == '1' then ReservedValue();
shift_type = DecodeShift(shift);
shift_amount = UInt(imm6);
invert = (N == '1');
```

Assembler symbols

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>`: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>`: Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>`: Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
ROR  when shift = 11 <amount>

For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

\[
\text{bits(datasize)} \text{ operand1} = X[n]; \\
\text{bits(datasize)} \text{ operand2} = \text{ShiftReg}(m, \text{shift_type}, \text{shift_amount}); \\
\text{if invert then operand2} = \text{NOT(operand2)}; \\
\text{case op of} \\
\quad \text{when LogicalOp\_AND result} = \text{operand1 AND operand2}; \\

\quad \text{when LogicalOp\_EOR result} = \text{operand1 EOR operand2}; \\
\text{if setflags then} \\
\quad \text{PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';} \\
\text{X[d] = result;}
\]
C6.6.25  BICS (shifted register)

Bitwise bit clear (shifted register) performs a bitwise AND of a register value and the complement of a shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

32-bit variant

Applies when $sf = 0$.

BICS $<Wd>, <Wm>, <Wn>{, <shift> #<amount>}$

64-bit variant

Applies when $sf = 1$.

BICS $<Xd>, <Xm>, <Xn>{, <shift> #<amount>}$

26-bit signed PC-relative branch offset variant

BL \(<\text{label}>\)

*Decode for this encoding*

\[
\text{BranchType} \ \text{branch\_type} = \text{if} \ \text{op} = \text{'1'} \ \text{then} \ \text{BranchType\_CALL} \ \text{else} \ \text{BranchType\_JMP};
\]
\[
\text{bits(64) offset} = \text{SignExtend(imm26:00', 64)};
\]

*Assembler symbols*

\(<\text{label}>\) Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

*Operation*

\[
\text{if} \ \text{branch\_type} = \text{BranchType\_CALL} \ \text{then} \ X[30] = \text{PC}[] + 4;
\]
\[
\text{BranchTo(\text{PC}[] + \text{offset}, \text{branch\_type});}
\]
C6.6.27  BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 3 2 1 0 | 5 4 3 2 1 0 5 4 3 2 1 0]
1 1 0 1 0 1 | 0 0 1 1 1 1 0 0 0 0 0 0 | Rn | 0 0 0 0 0
```

*Integer variant*

BLR <Xn>

*Decode for this encoding*

```python
integer n = UInt(Rn);
BranchType branch_type;

    case op of
        when '00' branch_type = BranchType_JMP;
        when '01' branch_type = BranchType_CALL;
        when '10' branch_type = BranchType_RET;
        otherwise UnallocatedEncoding();
```

*Assembler symbols*

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

*Operation*

```python
bits(64) target = X[n];

    if branch_type == BranchType_CALL then X[30] = PC[] + 4;
    BranchTo(target, branch_type);
```
C6.6.28    BR

Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.

---

**Integer variant**

BR `<Xn>`

**Decode for this encoding**

```plaintext
integer n = UInt(Rn);
BranchType branch_type;

case op of
  when '00' branch_type = BranchType_JMP;
  when '01' branch_type = BranchType_CALL;
  when '10' branch_type = BranchType_RET;
  otherwise UnallocatedEncoding();
```

**Assembler symbols**

`<Xn>` Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

**Operation**

```plaintext
bits(64) target = X[n];

if branch_type == BranchType_CALL then X[30] = PC[] + 4;
BranchTo(target, branch_type);
```
C6.6.29  BRK

Breakpoint instruction causes a Software Breakpoint Instruction exception. The PE records the exception in ESR_ELx, using the EC value 0x3c, and captures the value of the immediate argument in ESR_ELx.ISS.

\[
\begin{array}{cccccccccccc}
\text{31} & \text{30} & \text{29} & \text{28} & \text{27} & \text{26} & \text{25} & \text{24} & \text{23} & \text{22} & \text{21} & \text{20} \\

<Xn>    Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>    Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<nzcv>  Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
<cond>  Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bit carry_in = '0';

if ConditionHolds(condition) then
    if sub_op then
        operand2 = NOT(operand2);
        carry_in = '1';
    (-, flags) = AddWithCarry(operand1, operand2, carry_in);
PSTATE.<N,Z,C,V> = flags;
C6.6.36 CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when $sf = 0$.

CINC <Wd>, <Wn>, <cond>

is equivalent to

CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when $Rn == Rm$.

### 64-bit variant

Applies when $sf = 1$.

CINC <Xd>, <Xn>, <cond>

is equivalent to

CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when $Rn == Rm$.

### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- `<cond>` Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

### Operation

The description of CSINC gives the operational pseudocode for this instruction.
C6.6.37 CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINV instruction. This means that:

• The encodings in this description are named to match the encodings of CSINV.

• The description of CSINV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

CINV \(<Wd>, <Wn>, <cond>\)

is equivalent to

CSINV \(<Wd>, <Wn>, <Wn>, \text{invert}(<cond>)\)

and is the preferred disassembly when \( Rn == Rm \).

### 64-bit variant

Applies when \( sf = 1 \).

CINV \(<Xd>, <Xn>, <cond>\)

is equivalent to

CSINV \(<Xd>, <Xn>, <Xn>, \text{invert}(<cond>)\)

and is the preferred disassembly when \( Rn == Rm \).

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<\text{cond}>\) Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

### Operation

The description of CSINV gives the operational pseudocode for this instruction.
C6.6.38   CLREX

Clear Exclusive clears the local monitor of the executing PE.

```
+----------------------------------+
| 31 30 29 28 27 26 25 24 23 22 21 |
| 19 18 17 16 15 14 13 12 11  10  9 |
|  8   7   6   5   4   3   2   1   0 |
+----------------------------------+
```

**System variant**

CLREX {#imm}

**Decode for this encoding**

// CRm field is ignored

**Assembler symbols**

<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

**Operation**

ClearExclusiveLocal(ProcessorID());
C6.6.39 CLS

Count leading sign bits: Rd = CLS(Rn)

32-bit variant
Applies when \( sf = 0 \).

\[
\text{CLS } <Wd>, <Wn>
\]

64-bit variant
Applies when \( sf = 1 \).

\[
\text{CLS } <Xd>, <Xn>
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then 64 else 32}; \\
\text{CountOp opcode} &= \text{if } \text{op} == '0' \text{ then CountOp_CLZ else CountOp_CLS};
\end{align*}
\]

Assembler symbols

\[
\begin{align*}
<Wd> & \quad \text{Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.} \\
<Wn> & \quad \text{Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.} \\
<Xd> & \quad \text{Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.} \\
<Xn> & \quad \text{Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.}
\end{align*}
\]

Operation

\[
\begin{align*}
\text{integer } \text{result}; \\
\text{bits(\text{datasize}) } \text{operand1} &= X[n]; \\
\text{if } \text{opcode} == \text{CountOp_CLZ} \text{ then} \\
& \quad \text{result} = \text{CountLeadingZeroBits(operand1)}; \\
\text{else} \\
& \quad \text{result} = \text{CountLeadingSignBits(operand1)}; \\
X[d] &= \text{result}<\text{datasize}-1:0>;
\end{align*}
\]
C6.6.40   CLZ

Count leading zero bits : Rd = CLZ(Rn)

32-bit variant
Applies when sf = 0.
CLZ <Wd>, <Wn>

64-bit variant
Applies when sf = 1.
CLZ <Xd>, <Xn>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
CountOp opcode = if op == '0' then CountOp_CLZ else CountOp_CLS;

Assembler symbols

<Wd>  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

integer result;
bits(datasize) operand1 = X[n];
if opcode == CountOp_CLZ then
    result = CountLeadingZeroBits(operand1);
else
    result = CountLeadingSignBits(operand1);
X[d] = result<datasize-1:0>;}
C6.6.41  CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the $<Rm>$ register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when $sf = 0$.

\[
\text{CMN} \ <Wn|WSP>, \ <Wm>\{, \ <extend> \ {#<amount>}\}
\]

is equivalent to

\[
\text{ADDS} \ WZR, \ <Wn|WSP>, \ <Wm>\{, \ <extend> \ {#<amount>}\}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when $sf = 1$.

\[
\text{CMN} \ <Xn|SP>, \ <R><m>\{, \ <extend> \ {#<amount>}\}
\]

is equivalent to

\[
\text{ADDS} \ XZR, \ <Xn|SP>, \ <R><m>\{, \ <extend> \ {#<amount>}\}
\]

and is always the preferred disassembly.

### Assembler symbols

- $<Wn|WSP>$ Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- $<Wm>$ Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<Xn|SP>$ Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- $<R>$ Is a width specifier, encoded in the "option" field. It can have the following values:
  - W when option = 00x
  - W when option = 010
  - X when option = x11
  - W when option = 10x
  - W when option = 110
- $<m>$ Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB  when option = 000
- UXTH  when option = 001
- LSL|UXTW when option = 010
- UTXT  when option = 011
- SXTB  when option = 100
- SXTH  when option = 101
- SXTW when option = 110
- SXTX  when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB  when option = 000
- UXTH  when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB  when option = 100
- SXTH  when option = 101
- SXTW when option = 110
- SXTX  when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UTXT when "option" is '011'.

Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

The description of ADDS (extended register) gives the operational pseudocode for this instruction.
C6.6.42  CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (immediate) instruction. This means that:

•  The encodings in this description are named to match the encodings of ADDS (immediate).
•  The description of ADDS (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CMN} \ <\text{Wn}|\text{WSP}>, \ #<\text{imm}\rangle \{, \ <\text{shift}\}\}
\]

is equivalent to

\[
\text{ADDS} \ \text{WZR}, \ <\text{Wn}|\text{WSP}>, \ #<\text{imm}\rangle \{, \ <\text{shift}\}\}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CMN} \ <\text{Xn}|\text{SP}>, \ #<\text{imm}\rangle \{, \ <\text{shift}\}\}
\]

is equivalent to

\[
\text{ADDS} \ \text{XZR}, \ <\text{Xn}|\text{SP}>, \ #<\text{imm}\rangle \{, \ <\text{shift}\}\}
\]

and is always the preferred disassembly.

Assembler symbols

\(<\text{Wn}|\text{WSP}>\)  Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<\text{Xn}|\text{SP}>\)  Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<\text{imm}>\)  Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

\(<\text{shift}>\)  Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

| LSL #0 | when shift = 00  |
| LSL #12 | when shift = 01  |

It is reserved when shift = 1x.

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.
C6.6.43  CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CMN} \ <Wn>, \ <Wm> \{, \text{<shift>} \ #\text{<amount>}\}
\]

is equivalent to

\[
\text{ADDS} \ \text{WZR}, \ <Wn>, \ <Wm> \{, \text{<shift>} \ #\text{<amount>}\}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CMN} \ <Xn>, \ <Xm> \{, \text{<shift>} \ #\text{<amount>}\}
\]

is equivalent to

\[
\text{ADDS} \ \text{XZR}, \ <Xn>, \ <Xm> \{, \text{<shift>} \ #\text{<amount>}\}
\]

and is always the preferred disassembly.

Assembler symbols

- \(<Wm>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - It is reserved when \( \text{shift} = 11 \).
- \(<\text{amount}>\) is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 32-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.
C6.6.44  **CMP (extended register)**

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the \(<Rm>\) register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the **SUBS (extended register)** instruction. This means that:

- The encodings in this description are named to match the encodings of **SUBS (extended register)**.
- The description of **SUBS (extended register)** gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \(sf = 0\).

\[
\text{CMP } <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
\]

is equivalent to

\[
\text{SUBS } WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \(sf = 1\).

\[
\text{CMP } <Xn|SP>, <R>m>{, <extend> {#<amount>}}
\]

is equivalent to

\[
\text{SUBS } XZR, <Xn|SP>, <R>m>{, <extend> {#<amount>}}
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wn|WSP>\) Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn|SP>\) Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<R>\) Is a width specifier, encoded in the "option" field. It can have the following values:
  - \(W\) when option = 00x
  - \(W\) when option = 010
  - \(X\) when option = x11
  - \(W\) when option = 10x
  - \(W\) when option = 110
- \(<m>\) Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTXT when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.
C6.6.45 **CMP (immediate)**

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the **SUBS (immediate)** instruction. This means that:

- The encodings in this description are named to match the encodings of **SUBS (immediate)**.
- The description of **SUBS (immediate)** gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{CMP } <Wn|WSP>, \#<imm>{, <shift>}
\]

is equivalent to

\[
\text{SUBS } WZR, <Wn|WSP>, \#<imm> {, <shift>}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{CMP } <Xn|SP>, \#<imm>{, <shift>}
\]

is equivalent to

\[
\text{SUBS } XZR, <Xn|SP>, \#<imm> {, <shift>}
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wn|WSP>\) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Xn|SP>\) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<imm>\) Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- \(<shift>\) Is the optional left shift to apply to the immediate, defaulting to LSL \#0 and encoded in the "shift" field. It can have the following values:
  - LSL \#0 when \( shift = 00 \)
  - LSL \#12 when \( shift = 01 \)
  - It is reserved when \( shift = 1x \).

### Operation

The description of **SUBS (immediate)** gives the operational pseudocode for this instruction.
C6.6.46  CMP (shifted register)

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CMP } <Wn>, <Wm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{SUBS WZR, } <Wn>, <Wm> {, <shift> #<amount>}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CMP } <Xn>, <Xm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{SUBS XZR, } <Xn>, <Xm> {, <shift> #<amount>}
\]

and is always the preferred disassembly.

Assembler symbols

- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<shift>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
  - It is reserved when shift = 11.
- \(<amount>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.
C6.6.47 CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSNEG instruction. This means that:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf = 0.

CNEG <Wd>, <Wn>, <cond>
is equivalent to

CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit variant

Applies when sf = 1.

CNEG <Xd>, <Xn>, <cond>
is equivalent to

CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.
C6.6.48  CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It is an OPTIONAL instruction. It takes an input CRC value in the first source operand, performs a CRC on an input value in the second source operand that can be 8, 16, 32, or 64 bits, and returns the output CRC value. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

**CRC32B variant**

Applies when \( sf = 0 && sz = 00 \).

CRC32B \(<Wd>, <Wn>, <Wm>\)

**CRC32H variant**

Applies when \( sf = 0 && sz = 01 \).

CRC32H \(<Wd>, <Wn>, <Wm>\)

**CRC32W variant**

Applies when \( sf = 0 && sz = 10 \).

CRC32W \(<Wd>, <Wn>, <Wm>\)

**CRC32X variant**

Applies when \( sf = 1 && sz = 11 \).

CRC32X \(<Wd>, <Wn>, <Xm>\)

**Decode for all variants of this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UnallocatedEncoding();
if sf == '0' && sz == '11' then UnallocatedEncoding();
integer size = 8 << UInt(sz);  // 2-bit size field -> 8, 16, 32, 64
boolean crc32c = (C == '1');
```

**Assembler symbols**

- \(<Wd>\): Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
- \(<Wn>\): Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
- \(<Xm>\): Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
- \(<Wm>\): Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

**Operation**

```
if !HaveCRCExt() then
 UnallocatedEncoding();
```
bits(32) acc = X[n]; // accumulator
bits(size) val = X[m]; // input value
bits(32) poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;

bits(32+size) tempacc = BitReverse(acc) : Zeros(size);
buts(size+32) tempval = BitReverse(val) : Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
### CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It is an **optional** instruction. It takes an input CRC value in the first source operand, performs a CRC on an input value in the second source operand that can be 8, 16, 32, or 64 bits, and returns the output CRC value. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

#### CRC32CB variant
Applies when $sf = 0 \&\& sz = 00$.

CRC32CB `<Wd>, <Wn>, <Wm>`

#### CRC32CH variant
Applies when $sf = 0 \&\& sz = 01$.

CRC32CH `<Wd>, <Wn>, <Wm>`

#### CRC32CW variant
Applies when $sf = 0 \&\& sz = 10$.

CRC32CW `<Wd>, <Wn>, <Wm>`

#### CRC32CX variant
Applies when $sf = 1 \&\& sz = 11$.

CRC32CX `<Wd>, <Wn>, <Xm>`

#### Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UnallocatedEncoding();
if sf == '0' && sz == '11' then UnallocatedEncoding();
integer size = 8 << UInt(sz);  // 2-bit size field -> 8, 16, 32, 64
boolean crc32c = (C == '1');
```

#### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
- `<Wm>` Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

#### Operation

```plaintext
if !HaveCRCExt() then
  UnallocatedEncoding();
```
bits(32) acc = X[n]; // accumulator
bits(size) val = X[m]; // input value
bits(32) poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;

bits(32+size) tempacc = BitReverse(acc) : Zeros(size);
bits(size+32) tempval = BitReverse(val) : Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
C6.6.50 CSEL

Conditional Select returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CSEL} \ <Wd>, \ <Wn>, \ <Wm>, \ <\text{cond}>
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CSEL} \ <Xd>, \ <Xn>, \ <Xm>, \ <\text{cond}>
\]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then 64 else 32; } \\
\text{bits}(4) \text{ condition} &= \text{cond; } \\
\text{boolean } \text{else_inv} &= (\text{op} == '1'); \\
\text{boolean } \text{else_inc} &= (o2 == '1');
\end{align*}
\]

**Assembler symbols**

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{cond}>\) Is one of the standard conditions, encoded in the "cond" field in the standard way.

**Operation**

\[
\begin{align*}
\text{bits(\text{datasize}) result; } \\
\text{bits(\text{datasize}) operand1} &= X[n]; \\
\text{bits(\text{datasize}) operand2} &= X[m]; \\
\text{if } \text{ConditionHolds(\text{condition})} \text{ then } \\
\text{result} &= \text{operand1}; \\
\text{else} \\
\text{result} &= \text{operand2}; \\
\text{if } \text{else_inv} \text{ then result} &= \text{NOT(result); } \\
\text{if } \text{else_inc} \text{ then result} &= \text{result} + 1;
\end{align*}
\]

\( X[d] = \text{result}; \)
C6.6.51 CSET

Conditional Set sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when sf = 0.

CSET <Wd>, <cond>

is equivalent to

CSINC <Wd>, WZR, WZR, invert(<cond>)

and is always the preferred disassembly.

### 64-bit variant

Applies when sf = 1.

CSET <Xd>, <cond>

is equivalent to

CSINC <Xd>, XZR, XZR, invert(<cond>)

and is always the preferred disassembly.

### Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

### Operation

The description of CSINC gives the operational pseudocode for this instruction.
C6.6.52 **CSETM**

Conditional Set Mask sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when \( sf = 0 \).

CSETM \(<Wd>, <cond>\)

is equivalent to

CSINV \(<Wd>, WZR, WZR, invert(<cond>)\)

and is always the preferred disassembly.

**64-bit variant**

Applies when \( sf = 1 \).

CSETM \(<Xd>, <cond>\)

is equivalent to

CSINV \(<Xd>, XZR, XZR, invert(<cond>)\)

and is always the preferred disassembly.

**Assembler symbols**

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{cond}>\) Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

**Operation**

The description of CSINV gives the operational pseudocode for this instruction.
C6.6.53  CSINC

Conditional Select Increment returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC and CSET. See the Alias conditions table for details of when each alias is preferred.

32-bit variant
Applies when \( sf = 0 \).

\[
\text{CSINC} \ <Wd>, \ <Wn>, \ <Wm>, \ <\text{cond}>
\]

64-bit variant
Applies when \( sf = 1 \).

\[
\text{CSINC} \ <Xd>, \ <Xn>, \ <Xm>, \ <\text{cond}>
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(\text{Rd}); \\
\text{integer } n &= \text{UInt}(\text{Rn}); \\
\text{integer } m &= \text{UInt}(\text{Rm}); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then 64 else 32}; \\
\text{bits(4) } \text{condition} &= \text{cond}; \\
\text{boolean } \text{else}_\text{inv} &= (\text{op} == '1'); \\
\text{boolean } \text{else}_\text{inc} &= (o2 == '1');
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>

<td>CSET</td>
<td>( Rm = '11111' ) &amp;&amp; ( \text{cond} != '111x' ) &amp;&amp; ( Rn == '11111' )</td>
</tr>
</tbody>
</table>

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(< Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{cond}>\) Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(condition) then
  result = operand1;
else
  result = operand2;
  if else_inv then result = NOT(result);
  if else_inc then result = result + 1;

X[d] = result;
C6.6.54  CSINV

Conditional Select Invert returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV and CSETM. See the Alias conditions table for details of when each alias is preferred.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CSINV} \ <Wd>, <Wn>, <Wm>, <\text{cond}>
\]

64-bit variant

Applies when \( sf = 1 \).

X[d] = result;
C6.6.56 DC

Data Cache operation. For more information, see *A64 system instructions for cache maintenance* on page C5-315.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

**System variant**

DC <dc_op>, <Xt>

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>, <Xt>

and is the preferred disassembly when SysOp(op1, '0111', CRm, op2) == Sys_DC.

**Assembler symbols**

- `<dc_op>` is a DC operation name, as listed for the DC system operation group, encoded in the "op1:CRm:op2" field. It can have the following values:
  - IVAC when op1 = 000, CRm = 0110, op2 = 001
  - ISW when op1 = 000, CRm = 0110, op2 = 010
  - CSW when op1 = 000, CRm = 1010, op2 = 010
  - CISW when op1 = 000, CRm = 1110, op2 = 010
  - ZVA when op1 = 011, CRm = 0100, op2 = 001
  - CVAC when op1 = 011, CRm = 1010, op2 = 001
  - CVAU when op1 = 011, CRm = 1011, op2 = 001
  - CIVAC when op1 = 011, CRm = 1110, op2 = 001

- `<op1>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

- `<Cm>` is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

- `<op2>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

- `<Xt>` is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.6.57 DCPS1

Debug Change PE State to EL1 allows the debugger to move the PE into EL1 from a lower Exception Level or to a specific mode at the current Exception Level.

If the PE is at EL1 or lower, then the PE enters EL1h.

If the PE is at an Exception Level higher than EL1, then the PE does not change Exception Level but selects use of the stack pointer for the current Exception Level by updating PSTATE.SP.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of this instructions, see DCPS on page H2-5003.

```
|31 30 29 28|27 26 25 24|23 22 21 20|   |   | 5 4 3 2 1 0 |

```

**System variant**

DCPS1 {#<imm>}

**Decode for this encoding**

```
bits(2) target_level = LL;
if LL == '00' then UnallocatedEncoding();
if !Halted() then AArch64.UndefinedFault();
```

**Assembler symbols**

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

**Operation**

DCPSInstruction(target_level);
C6.6.58      DCPS2

Debug Change PE State to EL2 allows the debugger to move the PE into EL2 from a lower Exception Level or to a specific mode at the current Exception Level.

If the PE is at EL2 or lower, then the PE enters EL2h.

If the PE is at an Exception Level higher than EL2, then the PE does not change Exception Level but selects use of the stack pointer for the current Exception Level by updating PSTATE.SP.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of this instruction, see DCPS on page H2-5003.

```

System variant
DCPS2 {#<imm>}

Decode for this encoding
bits(2) target_level = LL;
if LL == "00" then UnallocatedEncoding();
if !Halted() then AArch64.UndefineFault();

Assembler symbols
<imm>    Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation
DCPSInstruction(target_level);
C6.6.59   DCPS3

Debug Change PE State to EL3 allows the debugger to move the PE into EL3 from a lower Exception Level or to a specific mode at the current Exception Level. The PE enters EL3h. This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of this instructions, see DCPS on page H2-5003.

System variant

DCPS3 {#imm}

Decode for this encoding

bits(2) target_level = LL;
if LL == '00' then UnallocatedEncoding();
if !Halted() then AArch64.UndefiedFault();

Assembler symbols

<imm>  Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

DCPSInstruction(target_level);
C6.6.60 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see Data Memory Barrier (DMB) on page B2-87.

MemBarrierOp op;
MBReqDomain domain;
MBReqTypes types;

case opc of
  when '00' op = MemBarrierOp_DSB;
  when '01' op = MemBarrierOp_DMB;
  when '10' op = MemBarrierOp_ISB;
  otherwise UnallocatedEncoding();

case CRm<3:2> of
  when '00' domain = MBReqDomain_OuterShareable;
  when '01' domain = MBReqDomain_Nonshareable;
  when '10' domain = MBReqDomain_InnerShareable;
  when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
  when '01' types = MBReqTypes_Reads;
  when '10' types = MBReqTypes_Writes;
  when '11' types = MBReqTypes_All;
  otherwise
    types = MBReqTypes_All;
    domain = MBReqDomain_FullSystem;

Assembler symbols
<option> Specifies the limitation on the barrier operation. Values are:

SY Full system is the required shareability domain, reads and writes are the required access types in both Group A on page B2-87 and Group B on page B2-88. This option is referred to as the full system DMB. Encoded as CRm = 0b1111.

ST Full system is the required shareability domain, writes are the required access type in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b1110.

LD Full system is the required shareability domain, reads are the required access type in Group A on page B2-87, and reads and writes are the required access types in Group B on page B2-88. Encoded as CRm = 0b1101.

ISH Inner Shareable is the required shareability domain, reads and writes are the required access types in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b1011.

ISHST Inner Shareable is the required shareability domain, writes are the required access type in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b1010.
ISHLD  Inner Shareable is the required shareability domain, reads are the required access type in Group A on page B2-87, and reads and writes are the required access types in Group B on page B2-88. Encoded as CRm = 0b1001.

NSH  Non-shareable is the required shareability domain, reads and writes are the required access types in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b0111.

NSHST  Non-shareable is the required shareability domain, writes are the required access type in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b0110.

NSHLD  Non-shareable is the required shareability domain, reads are the required access type in Group B on page B2-88. Encoded as CRm = 0b0101.

OSH  Outer Shareable is the required shareability domain, reads and writes are the required access types in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b0011.

OSHST  Outer Shareable is the required shareability domain, writes are the required access type in both Group A on page B2-87 and Group B on page B2-88. Encoded as CRm = 0b0010.

OSHLD  Outer Shareable is the required shareability domain, reads are the required access type in Group A on page B2-87, and reads and writes are the required access types in Group B on page B2-88. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system operation, but software must not rely on this behavior.

<imm>  Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

```c
case op of
  when MemBarrierOp_DSB
    DataSynchronizationBarrier(domain, types);
  when MemBarrierOp_DMB
    DataMemoryBarrier(domain, types);
  when MemBarrierOp_ISS
    InstructionsSynchronizationBarrier();

**System variant**

DSB <option>|#<imm>

**Decode for this encoding**

```c
MemBarrierOp op;
MBReqDomain domain;
MBReqTypes types;

case opc of
  when '00' op = MemBarrierOp_DSB;
  when '01' op = MemBarrierOp_DMB;
  when '10' op = MemBarrierOp_ISB;
  otherwise UnallocatedEncoding();

case CRm<3:2> of
  when '00' domain = MBReqDomain_OuterShareable;
  when '01' domain = MBReqDomain_Nonshareable;
  when '10' domain = MBReqDomain_InnerShareable;
  when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
  when '01' types = MBReqTypes_Reads;
  when '10' types = MBReqTypes_Writes;
  when '11' types = MBReqTypes_All;
  otherwise
    types = MBReqTypes_All;
    domain = MBReqDomain_FullSystem;
```

**Assembler symbols**

<option>  

Specifies the limitation on the barrier operation. Values are:

- **SY**  
  Full system is the required shareability domain, reads and writes are the required access types in both *Group A on page B2-87* and *Group B on page B2-88*. This option is referred to as the full system DMB. Encoded as CRm = 0b1111.

- **ST**  
  Full system is the required shareability domain, writes are the required access type in both *Group A on page B2-87* and *Group B on page B2-88*. Encoded as CRm = 0b1110.

- **LD**  
  Full system is the required shareability domain, reads are the required access type in *Group A on page B2-87*, and reads and writes are the required access types in *Group B on page B2-88*. Encoded as CRm = 0b1101.

- **ISH**  
  Inner Shareable is the required shareability domain, reads and writes are the required access types in both *Group A on page B2-87* and *Group B on page B2-88*. Encoded as CRm = 0b1011.

- **ISHST**  
  Inner Shareable is the required shareability domain, writes are the required access type in both *Group A on page B2-87* and *Group B on page B2-88*. Encoded as CRm = 0b1010.
ISHLD Inner Shareable is the required shareability domain, reads are the required access type in *Group A* on page B2-87, and reads and writes are the required access types in *Group B* on page B2-88. Encoded as CRm = 0b1001.

NSH Non-shareable is the required shareability domain, reads and writes are the required access types in both *Group A* on page B2-87 and *Group B* on page B2-88. Encoded as CRm = 0b0111.

NSHST Non-shareable is the required shareability domain, writes are the required access types in both *Group A* on page B2-87 and *Group B* on page B2-88. Encoded as CRm = 0b0110.

NSHLD Non-shareable is the required shareability domain, reads are the required access type in *Group A* on page B2-87, and reads and writes are the required access types in *Group B* on page B2-88. Encoded as CRm = 0b0101.

OSH Outer Shareable is the required shareability domain, reads and writes are the required access types in both *Group A* on page B2-87 and *Group B* on page B2-88. Encoded as CRm = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type in both *Group A* on page B2-87 and *Group B* on page B2-88. Encoded as CRm = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type in *Group A* on page B2-87, and reads and writes are the required access types in *Group B* on page B2-88. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system operation, but software must not rely on this behavior.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

**Operation**

```plaintext
case op of
  when MemBarrierOp_DSB
    DataSynchronizationBarrier(domain, types);
  when MemBarrierOp_DMB
    DataMemoryBarrier(domain, types);
  when MemBarrierOp_ISB
    InstructionsSynchronizationBarrier();
```
C6.6.63  EON (shifted register)

Bitwise Exclusive OR NOT (shifted register) performs a bitwise Exclusive OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{EON} \: <Wd>, \: <Wn>, \: <Wm>\{, \: <\text{shift}> \: \#<\text{amount}>\}
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{EON} \: <Xd>, \: <Xn>, \: <Xm>\{, \: <\text{shift}> \: \#<\text{amount}>\}
\]

Decode for all variants of this encoding

if setflags then
  PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
C6.6.66   ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores PSTATE from the SPSR, and branches to the address held in the ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal return events from AArch64 state on page D1-1534.

ERET will cause an Undefined Instruction exception if executed in EL0.

```asm
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 8 |7 6 5 4 |3 2 1 0 ]
  1 1 0 1 0 1 1 0 1 0 0 1 1 1 1 0 0 0 0 0 0 1 1 1 1 1 0 0 0 0 0
```

**System variant**

ERET

**Decode for this encoding**

if PSTATE.EL == EL0 then UnallocatedEncoding();

**Operation**

`AArch64.ExceptionReturn(ELR[], SPSR[]);`
C6.6.67   EXTR

Extract register extracts a register from a pair of registers.

This instruction is used by the alias ROR (immediate). See the Alias conditions table for details of when each alias is preferred.

### 32-bit variant

Applies when \( sf = 0 \land N = 0 \land imms = 0 \times \)xxx.

\[
\text{EXTR} \ <Wd>, <Wn>, <Wm>, \ #<lsb>
\]

### 64-bit variant

Applies when \( sf = 1 \land N = 1 \).

\[
\text{EXTR} \ <Xd>, <Xn>, <Xm>, \ #<lsb>
\]

### Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf = '1' \text{ then 64 else 32}; \\
\text{integer } \text{lsb} &= \text{UInt}(imms);
\end{align*}
\]

\[
\text{if } N \neq sf \text{ then UnallocatedEncoding();} \\
\text{if } sf = '0' \land \text{imms<5>} = '1' \text{ then ReservedValue();} \\
\text{lsb} &= \text{UInt}(imms);
\]

when SystemHintOp_SEVL
  EventRegisterSet();

otherwise // do nothing
C6.6.69   HLT

Halt instruction causes a Halting Instruction debug event to occur.

\[
\begin{array}{cccccccccc}
11010100 & | & | & 5 & 4 & 3 & 2 & 1 & 0 \\
00000100 & | & imm16 & 00000000
\end{array}
\]

**System variant**

HLT #<imm>

**Decode for this encoding**

if EDSCR.HDE == '0' || !HaltingAllowed() then UndefinedFault();

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

Halt(DebugHalt_HaltInstruction);
C6.6.70  HVC

Hypervisor Call causes an exception to EL2. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction:

- Is UNDEFINED in EL0, and Secure EL1.
- When SCR_EL3.HCE is set to 0, generates an Undefined Instruction exception.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception, using the EC value 0x16, and the value of the immediate argument. This is reported in:

- ESR_ELx, if the exception is taken to an Exception level that is using AArch64.
- HSR, if the exception is taken to an Exception level that is using AArch32. See Use of the HSR on page G4-4177.

| 1 1 0 1 0 0 0 0 | imm16 | 0 0 0 1 0 |

**System variant**

HVC #<imm>

**Decode for this encoding**

bits(16) imm = imm16;

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 & IsSecure()) then
  UnallocatedEncoding();

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then
  AArch64.UndefinedFault();
else
  AArch64.CallHypervisor(imm);
C6.6.71 IC

Instruction Cache operation. For more information, see *A64 system instructions for cache maintenance* on page C5-315.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

### System variant

IC `<ic_op>{, <Xt>}`

is equivalent to

SYS `#<op1>, C7, #<Cm>, #<op2>{, <Xt>}`

and is the preferred disassembly when `SysOp(op1,'0111',CRm,op2) == Sys_IC`.

### Assembler symbols

- `<ic_op>` Is an IC operation name, as listed for the IC system operation pages, encoded in the "op1:CRm:op2" field. It can have the following values:
  - IALLUIS when `op1 = 000`, `CRm = 0001`, `op2 = 000`
  - IALLU when `op1 = 000`, `CRm = 0101`, `op2 = 000`
  - IVAU when `op1 = 011`, `CRm = 0101`, `op2 = 001`
- `<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- `<Xt>` Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

### Operation

The description of SYS gives the operational pseudocode for this instruction.
C6.6.72   ISB

Instruction Synchronization Barrier flushes the pipeline in the PE, so that all instructions following the ISB are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the ISB instruction are visible to the instructions fetched after the ISB. Context changing operations include changing the ASID, TLB maintenance instructions, and all changes to the System registers. In addition, any branches that appear in program order after the ISB instruction are written into the branch prediction logic with the context that is visible after the ISB instruction. This is needed to ensure correct execution of the instruction stream. For more information, see Memory barriers on page B2-87.

System variant

Assembler symbols
\[
\text{<option>}
\]
Specifies an optional limitation on the barrier operation. Values are:
SY  Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.

All other encodings of CRm are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

\[
\text{<imm>}
\]
Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation
\[
\text{case op of}
\]
\[
\begin{align*}
\text{when MemBarrierOp_DSB}
& \text{ DataSynchronizationBarrier(domain, types);}
\end{align*}
\]
when MemBarrierOp_DMB
    DataMemoryBarrier(domain, types);
when MemBarrierOp_ISB
    InstructionSynchronizationBarrier();
C6.6.73   LDAR

Load-Acquire Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in 
Load-Acquire, Store-Release on page B2-90. For information about memory accesses see Load/Store addressing modes on page C1-126.

32-bit variant

Applies when size = 10.

**C6.6.76 LDAXP**

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-107. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page B2-90. For information about memory accesses see *Load/Store addressing modes* on page C1-126.

**32-bit variant**

Applies when \( sz = 0 \).

LDAXP \(<Wt1>, <Wt2>, [<Xn|SP>{,#0}]\)

**64-bit variant**

Applies when \( sz = 1 \).

LDAXP \(<Xt1>, <Xt2>, [<Xn|SP>{,#0}]\)

**Decode for all variants of this encoding**

C6.6.79   LDAXRH

Load-Acquire Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-107. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page B2-90. For information about memory accesses see Load/Store addressing modes on page C1-126.

No offset variant

C6.6.83  **LDR (immediate)**

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes on page C1-126*. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

else
    X[t] = data;

when MemOp_PREFETCH
    Prefetch(address, t<4:0>);
C6.6.85  LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about memory accesses, see *Load/Store addressing modes* on page C1-126.

32-bit variant

Applies when size = 10.

LDR <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

64-bit variant

Applies when size = 11.

LDR <Xt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

**Decode for all variants of this encoding**

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

**Assembler symbols**

<Wt>    Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>    Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<R>    Is the index width specifier, encoded in the "option" field. It can have the following values:
    W      when option = x10
    X      when option = x11

It is reserved when:
•     option = 00x.
•     option = 10x.

<m>    Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.
<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
    UXTW   when option = 010
    LSL    when option = 011
    SXTW   when option = 110
    SXTX   when option = 111
It is reserved when:

- option = 00x.
- option = 10x.

<amount>

For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #2 when S = 1

For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #3 when S = 1

Shared decode for all encodings

C6.6.87  LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see Load/Store addressing modes on page C1-126.

32-bit variant

LDRB <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

Decode for this encoding

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<2> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = .DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

Assembler symbols

<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<R>  Is the index width specifier, encoded in the "option" field. It can have the following values:
   W  when option = x10
   X  when option = x11
   It is reserved when:
      •  option = 00x.
      •  option = 10x.
<m>  Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.
<extend>  Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
   UXTW  when option = 010
   LSL  when option = 011
   SXTW  when option = 110
   SXTX  when option = 111
   It is reserved when:
      •  option = 00x.
      •  option = 10x.
<amount>  Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
   [absent]  when S = 0
   #0  when S = 1
Shared decode for all encodings

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
AccType acctype = AccType_NORMAL;
MemOp memop;
boolean signed;
integer regsize;

C6.6.88   LDRH (immediate)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see **Load/Store addressing modes on page C1-126**.

Post-index

```
|31 30 29 28|27 26 25 24|23 22 21 20|   |12|11 10 9| 5 4 | 0 |
|0 1 1 1 1|0 0 0 0 1 0|   |imm9 0 1  |Rn  |Rt |
```

Post-index variant

LDRH <Wt>, [<Xn|SP>], #<simm>

**Decode for this encoding**

```java
boolean wback = TRUE;
boolean postindex = TRUE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

```
|31 30 29 28|27 26 25 24|23 22 21 20|   |12|11 10 9| 5 4 | 0 |
|0 1 1 1 1|0 0 0 0 1 0|   |imm9 1 1  |Rn  |Rt |
```

Pre-index variant

LDRH <Wt>, [<Xn|SP>, #<simm>]

**Decode for this encoding**

```java
boolean wback = TRUE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

```
|31 30 29 28|27 26 25 24|23 22 21|   |10 9| 5 4 | 0 |
|0 1 1 1 1|0 1 0 1|   |imm12 |Rn  |Rt |
```

Unsigned offset variant

LDRH <Wt>, [<Xn|SP>{, #<pimm}>]

**Decode for this encoding**

```java
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```
Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRH (immediate) on page J1-5445.

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm> Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared decode for all encodings

integer n = Uint(Rn);

C6.6.89  LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-126.

### 32-bit variant

LDRH <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

#### Decode for this encoding

```plaintext
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

#### Notes for all encodings

For information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see Appendix J1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly LDRH (register) on page J1-5380.

### Assembler symbols

- `<Wt>`: Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>`: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<R>`: Is the index width specifier, encoded in the "option" field. It can have the following values:
  - `W` when option = x10
  - `X` when option = x11
  - It is reserved when:
    - option = 00x.
    - option = 10x.
- `<m>`: Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.
- `<extend>`: Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
  - `UXTW` when option = 010
  - LSL when option = 011
  - `SXTW` when option = 110
  - `SXTX` when option = 111
  - It is reserved when:
    - option = 00x.
    - option = 10x.
<amount> Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #1 when S = 1

Shared decode for all encodings

integer \( \text{shift} \) = if \( \text{S} \) = '1' then \( \text{scale} \) else 0;

**Assembler symbols**

\(<Wt>\) Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xt>\) Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\(<R>\) Is the index width specifier, encoded in the "option" field. It can have the following values:

- \(W\) when \( \text{option} = x10\)
- \(X\) when \( \text{option} = x11\)

It is reserved when:

- \( \text{option} = 00x\).
- \( \text{option} = 10x\).

\(<m>\) Is the number \([0-30]\) of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.

\(<\text{extend}>\) Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:

- \(\text{UXTW}\) when \( \text{option} = 010\)
- \(\text{LSL}\) when \( \text{option} = 011\)
- \(\text{SXTW}\) when \( \text{option} = 110\)
- \(\text{SXTX}\) when \( \text{option} = 111\)
It is reserved when:

- option = \(00x\).
- option = \(10x\).

<amount> Is the index shift amount, optional and defaulting to \#0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:

- [absent] when \(S = 0\)
- \#0 when \(S = 1\)

### Shared decode for all encodings

```plaintext

```
Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see Load/Store addressing modes on page C1-126.

64-bit variant

LDRSW <Xt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

Decode for this encoding

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<3> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<R> Is the index width specifier, encoded in the "option" field. It can have the following values:
W when option = x10
X when option = x11
It is reserved when:
• option = 00x.
• option = 10x.
<m> Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.
<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
UXTW when option = 010
LSL when option = 011
SXTW when option = 110
SXTX when option = 111
It is reserved when:
• option = 00x.
• option = 10x.
<amount> Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
#0 when S = 0

LDTR

Load Register (unprivileged) loads a word or doubleword from an address in memory, zero-extends it, and writes the result to a register. The address used for the load is calculated from a base register and an immediate offset. When executed at EL1, the memory access is restricted as if execution was at EL0. Otherwise, the access permission is for the Exception level at which the instruction is executed. For information about memory accesses see Load/Store addressing modes on page C1-126.

32-bit variant

Applies when size = 10.

LDTR <Wt>, [<Xn|SP>{, #<simm>}]

64-bit variant

Applies when size = 11.

C6.6.102  LDTRSW

Load Register Signed Word (unprivileged) loads a signed word from an address in memory, zero-extends it, and writes the result to a register. The address used for the load is calculated from a base register and an immediate offset. When executed at EL1, the memory access is restricted as if execution was at EL0. Otherwise, the access permission is for the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes on page C1-126.

Unscaled offset variant

LDTRSW <Xt>, [<Xn|SP>{, #<simm>}]

Decode for this encoding

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Xt>  Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>  Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

C6.6.109   LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-107. For information about memory accesses see Load/Store addressing modes on page C1-126.

32-bit variant
Applies when \( sz = 0 \).

\[
\text{LDXP } \langle \text{Wt1} \rangle, \langle \text{Wt2} \rangle, \{\langle \text{Xn}\mid\text{SP}\rangle\{,#0\}}
\]

64-bit variant
Applies when \( sz = 1 \).

\[
\text{LDXP } \langle \text{Xt1} \rangle, \langle \text{Xt2} \rangle, \{\langle \text{Xn}\mid\text{SP}\rangle\{,#0\}}
\]

Decode for all variants of this encoding

C6.6.112  LDXRH

Load Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-107. For information about memory accesses see Load/Store addressing modes on page C1-126.

No offset variant

LDXRH <Wt>, [<Xn|SP>{,#0}]

C6.6.113   LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is an alias of the LSLV instruction. This means that:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{LSL} \ <Wd>, \ <Wn>, \ <Wm>
\]

is equivalent to

\[
\text{LSLV} \ <Wd>, \ <Wn>, \ <Wm>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{LSL} \ <Xd>, \ <Xn>, \ <Xm>
\]

is equivalent to

\[
\text{LSLV} \ <Xd>, \ <Xn>, \ <Xm>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of LSLV gives the operational pseudocode for this instruction.
C6.6.114   LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \land N = 0 \land \text{imms} \neq 011111 \).

\[
\text{LSL} \ <Wd>, \ <Wn>, \ #<\text{shift}>
\]

is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #(-<\text{shift} \mod 32), \ #(31-<\text{shift}>)
\]

and is the preferred disassembly when \( \text{imms} + 1 = \text{immr} \).

### 64-bit variant

Applies when \( sf = 1 \land N = 1 \land \text{imms} \neq 111111 \).

\[
\text{LSL} \ <Xd>, \ <Xn>, \ #<\text{shift}>
\]

is equivalent to

\[
\text{UBFM} \ <Xd>, \ <Xn>, \ #(-<\text{shift} \mod 64), \ #(63-<\text{shift}>)
\]

and is the preferred disassembly when \( \text{imms} + 1 = \text{immr} \).

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{shift}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31.
  For the 64-bit variant: is the shift amount, in the range 0 to 63.

### Operation

The description of UBFM gives the operational pseudocode for this instruction.
C6.6.115   LSLV

Logical Shift Left Variable shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register). The alias is always the preferred disassembly.

32-bit variant
Applies when \( sf = 0 \).

\[
\text{LSLV } <Wd>, <Wn>, <Wm>
\]

64-bit variant
Applies when \( sf = 1 \).

\[
\text{LSLV } <Xd>, <Xn>, <Xm>
\]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then 64 else 32}; \\
\text{ShiftType } \text{shift\_type} &= \text{DecodeShift(op2)};
\end{align*}
\]

**Assembler symbols**

| <Wd> | Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field. |
| <Wn> | Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field. |
| <Wm> | Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field. |
| <Xd> | Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field. |
| <Xn> | Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field. |
| <Xm> | Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field. |

**Operation**

\[
\begin{align*}
\text{bits(datasize) result}; \\
\text{bits(datasize) operand2} &= X[m]; \\
\text{result} &= \text{ShiftReg}(n, \text{shift\_type}, \text{UInt(operand2)} \ MOD \ datasize); \\
X[d] &= \text{result};
\end{align*}
\]
C6.6.116   LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the LSRV instruction. This means that:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode for this instruction.

32-bit variant
Applies when $sf = 0$.

$LSR <Wd>, <Wn>, <Wm>$
is equivalent to

$LSRV <Wd>, <Wn>, <Wm>$
and is always the preferred disassembly.

64-bit variant
Applies when $sf = 1$.

$LSR <Xd>, <Xn>, <Xm>$
is equivalent to

$LSRV <Xd>, <Xn>, <Xm>$
and is always the preferred disassembly.

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wn>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

X[d] = result<destsize-1:0>;
```
C6.6.120  MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This instruction is an alias of the MSUB instruction. This means that:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode for this instruction.

32-bit variant
Applies when $sf = 0$.

MNEG $<Wd>$, $<Wn>$, $<Wm>$
is equivalent to

MSUB $<Wd>$, $<Wn>$, $<Wm>$, $WZR$
and is always the preferred disassembly.

64-bit variant
Applies when $sf = 1$.

MNEG $<Xd>$, $<Xn>$, $<Xm>$
is equivalent to

MSUB $<Xd>$, $<Xn>$, $<Xm>$, $XZR$
and is always the preferred disassembly.

Assembler symbols

- $<Wd>$  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$  Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- $<Wm>$  Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- $<Xd>$  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$  Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- $<Xm>$  Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation
The description of MSUB gives the operational pseudocode for this instruction.
C6.6.121  MOV (to/from SP)

Move between register and stack pointer : \(Rd = Rn\)

This instruction is an alias of the ADD (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \(sf = 0\).

\[MOV \langle Wd|WSP\rangle, \langle Wn|WSP\rangle\]

is equivalent to

\[ADD \langle Wd|WSP\rangle, \langle Wn|WSP\rangle, #0\]

and is the preferred disassembly when \((Rd == '11111' || Rn == '11111')\).

64-bit variant

Applies when \(sf = 1\).

\[MOV \langle Xd|SP\rangle, \langle Xn|SP\rangle\]

is equivalent to

\[ADD \langle Xd|SP\rangle, \langle Xn|SP\rangle, #0\]

and is the preferred disassembly when \((Rd == '11111' || Rn == '11111')\).

Assembler symbols

\(<Wd|WSP\rangle\) Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Wn|WSP\rangle\) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<Xd|SP\rangle\) Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Xn|SP\rangle\) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.
C6.6.122 MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This instruction is an alias of the MOVN instruction. This means that:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\texttt{MOV <Wd>, #<imm>}

is equivalent to

\texttt{MOVN <Wd>, #<imm16>, LSL <shift>}

and is the preferred disassembly when \(! (\text{IsZero}(\text{imm16}) \&\& \text{hw} \neq '00') \&\& \text{IsOnes}(\text{imm16})\).

64-bit variant

Applies when \( sf = 1 \).

\texttt{MOV <Xd>, #<imm>}

is equivalent to

\texttt{MOVN <Xd>, #<imm16>, LSL <shift>}

and is the preferred disassembly when \(! (\text{IsZero}(\text{imm16}) \&\& \text{hw} \neq '00')\).

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{imm}>\) For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff.
  - For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
- \(<\text{shift}>\) For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as \(<\text{shift}>\)
  - For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as \(<\text{shift}>\).

Operation

The description of MOVN gives the operational pseudocode for this instruction.
C6.6.123 MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This instruction is an alias of the MOVZ instruction. This means that:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

MOV \(<Wd>, \#<imm>\)

is equivalent to

MOVZ \(<Wd>, \#<imm16>, \text{LSL }<shift>\)

and is the preferred disassembly when \(! (\text{IsZero}(imm16) \&\& \text{hw} \neq '00')\).

64-bit variant

Applies when \( sf = 1 \).

MOV \(<Xd>, \#<imm>\)

is equivalent to

MOVZ \(<Xd>, \#<imm16>, \text{LSL }<shift>\)

and is the preferred disassembly when \(! (\text{IsZero}(imm16) \&\& \text{hw} \neq '00')\).

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<imm>\) For the 32-bit variant: is a 32-bit immediate which can be encoded in "imm16:hw".

for the 64-bit variant: is a 64-bit immediate which can be encoded in "imm16:hw".

\(<shift>\) For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as \(<shift>/16\).

For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as \(<shift>/16\).

Operation

The description of MOVZ gives the operational pseudocode for this instruction.
C6.6.124  MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This instruction is an alias of the ORR (immediate) instruction. This means that:

• The encodings in this description are named to match the encodings of ORR (immediate).
• The description of ORR (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 && N = 0 \).

\[
\text{MOV} <Wd|WSP>, \#<imm>
\]

is equivalent to

\[
\text{ORR} <Wd|WSP>, WZR, \#<imm>
\]

and is the preferred disassembly when \( ! \text{MoveWidePreferred}(sf, N, \text{imms}, \text{immr}) \).

64-bit variant

Applies when \( sf = 1 \).

\[
\text{MOV} <Xd|SP>, \#<imm>
\]

is equivalent to

\[
\text{ORR} <Xd|SP>, XZR, \#<imm>
\]

and is the preferred disassembly when \( ! \text{MoveWidePreferred}(sf, N, \text{imms}, \text{immr}) \).

Assembler symbols

\(<Wd|WSP>\)  Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Xd|SP>\)  Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<\text{imm}>\)  Is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.
C6.6.125  MOV (register)

Move (register) copies the value in a source register to the destination register.

This instruction is an alias of the ORR (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when $sf = 0$.

$\text{MOV } <Wd>, <Wm>$

is equivalent to

$\text{ORR } <Wd>, \text{WZR}, <Wm>$

and is always the preferred disassembly.

### 64-bit variant

Applies when $sf = 1$.

$\text{MOV } <Xd>, <Xm>$

is equivalent to

$\text{ORR } <Xd>, \text{XZR}, <Xm>$

and is always the preferred disassembly.

### Assembler symbols

- $<Wd>$  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wm>$  Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- $<Xd>$  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xm>$  Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

### Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.
C6.6.126 MOVK

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

2-bit variant
Applies when sf = 0.
MOVK <Wd>, #<imm>{, LSL #<shift>}

64-bit variant
Applies when sf = 1.
MOVK <Xd>, #<imm>{, LSL #<shift>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
binary(16) imm = imm16;
it integer pos;
MoveWideOp opcode;
case opc of
    when '00' opcode = MoveWideOp.N;
    when '10' opcode = MoveWideOp.Z;
    when '11' opcode = MoveWideOp.K;
    otherwise UnallocatedEncoding();
if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:"0000");

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

bits(datasize) result;
if opcode == MoveWideOp.K then
    result = X[d];
else
    result = Zeros();
result<pos+15:pos> = imm;
if opcode == MoveWideOp_N then
    result = NOT(result);
X[d] = result;
C6.6.127   MOVN

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate). See the Alias conditions table for details of when each alias is preferred.

32-bit variant

Applies when sf = 0.

MOVN <Wd>, #<imm>{, LSL #<shift>}

64-bit variant

Applies when sf = 1.

MOVN <Xd>, #<imm>{, LSL #<shift>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
bits(16) imm = imm16;
integer pos;
MoveWideOp opcode;

case opc of
  when '00' opcode = MoveWideOp_N;
  when '10' opcode = MoveWideOp_Z;
  when '11' opcode = MoveWideOp_K;
  otherwise UnallocatedEncoding();
if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>

<td>32-bit</td>
<td>! (IsZero(imm16) &amp;&amp; hw != '00') &amp;&amp; ! IsZeroes(imm16)</td>
</tr>
</tbody>
</table>

Assembler symbols

<Wd>   Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>   Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>  Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

**Operation**

```assembly
bits(datasize) result;
if opcode == MoveWideOp_K then
    result = X[d];
else
    result = Zeros();
result<pos+15:pos> = imm;
if opcode == MoveWideOp_N then
    result = NOT(result);
X[d] = result;
```
C6.6.128   MOVZ

Move wide with zero moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (wide immediate). See the Alias conditions table for details of when each alias is preferred.

32-bit variant
Applies when sf = 0.

MOVZ <Wd>, #<imm>{, LSL #<shift>}

64-bit variant
Applies when sf = 1.

MOVZ <Xd>, #<imm>{, LSL #<shift>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
bits(16) imm = imm16;
integer pos;
MoveWideOp opcode;

case opc of
  when '00' opcode = MoveWideOp_N;
  when '10' opcode = MoveWideOp_Z;
  when '11' opcode = MoveWideOp_K;
  otherwise UnallocatedEncoding();
if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');

Assembler symbols

<Wd>  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>  Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>  For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.
Operation

bits(datasize) result;

if opcode == MoveWideOp_K then
    result = X[d];
else
    result = Zeros();

result<pos+15:pos> = imm;
if opcode == MoveWideOp_N then
    result = NOT(result);
X[d] = result;
C6.6.129   MRS

Move System Register allows the PE to read an AArch64 System register into a general-purpose register.

System variant
MRS <Xt>, <systemreg>

Decode for this encoding

CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys.crm = UInt(CRm);
boolean read = (L == '1');

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

<systemreg> Is a system register name, encoded in the "o0:op1:CRn:CRm:op2".

Operation

if read then
    X[t] = System_Get(sys_op0, sys_op1, sys_crn, sys.crm, sys_op2);
else
    System_Put(sys_op0, sys_op1, sys_crn, sys.crm, sys_op2, X[t]);
C6.6.130 MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE, namely D, A, I, F, and SP. For more information, see PSTATE.

System variant
MSR <pstatefield>, #<imm>

Decode for this encoding

CheckSystemAccess('00', op1, '0100', CRm, op2, '11111', '0');

bits(4) operand = CRm;
PSTATEField field;
case op1:op2 of
  when '000 101' field = PSTATEField_SP;
  when '011 110' field = PSTATEField_DAIFSet;
  when '011 111' field = PSTATEField_DAIFClr;
  otherwise UnallocatedEncoding();

  // Check that an AArch64 MSR/MRS access to the DAIF flags is permitted
  if op1 == '011' && PSTATE.EL == EL0 && SCTLR_EL1.UMA == '0' then
    AArch64.SystemRegisterTrap(EL1, '00', op2, op1, '0100', '11111', CRm, '0');

Assembler symbols

<pstatefield> Is a PSTATE field name, encoded in the "op1:op2" field. It can have the following values:
  SPSet   when op1 = 000, op2 = 101
  DAIFSet when op1 = 011, op2 = 110
  DAIFClr when op1 = 011, op2 = 111

It is reserved when:
  • op1 = 000, op2 = 0xx.
  • op1 = 000, op2 = 100.
  • op1 = 000, op2 = 11x.
  • op1 = 001, op2 = xxx.
  • op1 = 010, op2 = xxx.
  • op1 = 011, op2 = 0xx.
  • op1 = 011, op2 = 10x.
  • op1 = 1xx, op2 = xxx.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

case field of
  when PSTATEField_SP
    PSTATE.SP = operand<0>;
  when PSTATEField_DAIFSet
    PSTATE.D = PSTATE.D OR operand<3>;
PSTATE.A = PSTATE.A OR operand<2>
PSTATE.I = PSTATE.I OR operand<1>
PSTATE.F = PSTATE.F OR operand<0>
when PSTATEField_DAIFCrl
PSTATE.D = PSTATE.D AND NOT(operand<3>)
PSTATE.A = PSTATE.A AND NOT(operand<2>)
PSTATE.I = PSTATE.I AND NOT(operand<1>)
PSTATE.F = PSTATE.F AND NOT(operand<0>)
C6.6.131   MSR (register)

Move general-purpose register to System Register allows the PE to write an AArch64 System register from a
general-purpose register.

System variant

MSR <systemreg>, <Xt>

Decode for this encoding

CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
boolean read = (L == '1');

Assembler symbols

<systemreg>   Is a system register name, encoded in the "o0:op1:CRn:CRm:op2".
<Xt>          Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

if read then
    X[t] = System_Get(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
else
    System_Put(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
C6.6.132 MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG. See the Alias conditions table for details of when each alias is preferred.

32-bit variant

Applies when \( sf = 0 \).

MSUB \(<Wd>, <Wn>, <Wm>, <Wa>\)

64-bit variant

Applies when \( sf = 1 \).

MSUB \(<Xd>, <Xn>, <Xm>, <Xa>\)

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d &= \text{ UInt}(Rd); \\
\text{integer } n &= \text{ UInt}(Rn); \\
\text{integer } m &= \text{ UInt}(Rm); \\
\text{integer } a &= \text{ UInt}(Ra); \\
\text{integer } destsize &= \text{ if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{integer } datasize &= destsize; \\
\text{boolean } sub\_op &= (o0 == '1');
\end{align*}
\]

\text{X[d] = result<destsize-1:0>;}
\]
C6.6.133  MUL

Multiply : \( Rd = Rn \times Rm \)

This instruction is an alias of the MADD instruction. This means that:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{MUL} \quad <Wd>, \quad <Wn>, \quad <Wm>
\]

is equivalent to

\[
\text{MADD} \quad <Wd>, \quad <Wn>, \quad <Wm>, \quad \text{WZR}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{MUL} \quad <Xd>, \quad <Xn>, \quad <Xm>
\]

is equivalent to

\[
\text{MADD} \quad <Xd>, \quad <Xn>, \quad <Xm>, \quad \text{XZR}
\]

and is always the preferred disassembly.

### Assembler symbols

- \( <Wd> \): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <Wn> \): Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \( <Wm> \): Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \( <Xd> \): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <Xn> \): Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \( <Xm> \): Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

### Operation

The description of MADD gives the operational pseudocode for this instruction.
**C6.6.134 MVN**

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This instruction is an alias of the ORN (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when $sf = 0$.

$MVN <Wd>, <Wm>{, <shift> #<amount>}$

is equivalent to

$ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}$

and is always the preferred disassembly.

### 64-bit variant

Applies when $sf = 1$.

$MVN <Xd>, <Xm>{, <shift> #<amount>}$

is equivalent to

$ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}$

and is always the preferred disassembly.

### Assembler symbols

- $<Wd>$: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wm>$: Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- $<Xd>$: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xm>$: Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- $<shift>$: Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
  - ROR when shift = 11
- $<amount>$: For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.
C6.6.135   NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This instruction is an alias of the SUB (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{NEG } <Wd>, <Wm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{SUB } <Wd>, \text{WZR}, <Wm> {, <shift> #<amount>}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{NEG } <Xd>, <Xm>{, <shift> #<amount>}
\]

is equivalent to

\[
\text{SUB } <Xd>, \text{XZR}, <Xm> {, <shift> #<amount>}
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - It is reserved when \( \text{shift} = 11 \).
- \(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.
C6.6.136   NEGS

Negate, setting flags, negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

• The encodings in this description are named to match the encodings of SUBS (shifted register).
• The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf = 0$.

NEGS $<Wd>$, $<Wm>$, {, $<shift>$ #<amount>} is equivalent to

SUBS $<Wd>$, WZR, $<Wm>$ {, $<shift>$ #<amount>}

and is always the preferred disassembly.

64-bit variant

Applies when $sf = 1$.

NEGS $<Xd>$, $<Xm>$, {, $<shift>$ #<amount>} is equivalent to

SUBS $<Xd>$, XZR, $<Xm>$ {, $<shift>$ #<amount>}

and is always the preferred disassembly.

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wm>$ Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xm>$ Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

$<shift>$ Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10
- It is reserved when shift = 11.

$<amount>$ For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

---

[Diagram of instruction encoding]
Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.
C6.6.137   NGC

Negate with Carry negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This instruction is an alias of the SBC instruction. This means that:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{NGC } <Wd>, <Wm>
\]

is equivalent to

\[
\text{SBC } <Wd>, WZR, <Wm>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{NGC } <Xd>, <Xm>
\]

is equivalent to

\[
\text{SBC } <Xd>, XZR, <Xm>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

### Operation

The description of SBC gives the operational pseudocode for this instruction.
C6.6.138   NGCS

Negate with Carry, setting flags, negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SBCS instruction. This means that:

- The encodings in this description are named to match the encodings of SBCS.
- The description of SBCS gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf = 0$.

NGCS <Wd>, <Wm>

is equivalent to

SBCS <Wd>, WZR, <Wm>

and is always the preferred disassembly.

64-bit variant

Applies when $sf = 1$.

NGCS <Xd>, <Xm>

is equivalent to

SBCS <Xd>, XZR, <Xm>

and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.
C6.6.139  NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

--- Note ---

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

This instruction is an alias of the HINT instruction. This means that:

- The encodings in this description are named to match the encodings of HINT.
- The description of HINT gives the operational pseudocode for this instruction.

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 7 5 4 3 2 1 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
|1 1 0 1 0 1 0 0 0 0 1 1 0 0 1 0 0 0 0 0 0 1 1 1 1 |
|CRm|op2|
```

**System variant**

NOP

is equivalent to

HINT #0

and is always the preferred disassembly.

**Operation**

The description of HINT gives the operational pseudocode for this instruction.
C6.6.140 **ORN (shifted register)**

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN. See the *Alias conditions* table for details of when each alias is preferred.

### 32-bit variant

Applies when $sf = 0$.

ORN $<Wd>$, $<Wn>$, $<Wm>$, $<$shift$>$ $#$<amount$>}$

### 64-bit variant

Applies when $sf = 1$.

ORN $<Xd>$, $<Xn>$, $<Xm>$, $<$shift$>$ $#$<amount$>}$

#### Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;
if sf == '0' && imm6<5> == '1' then ReservedValue();
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVN</td>
<td>Rn == '11111'</td>
</tr>
</tbody>
</table>

### Assembler symbols

- $<Wd>$: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Wm>$: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<Xd>$: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

<table>
<thead>
<tr>
<th>Shift Type</th>
<th>Shift Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSL</td>
<td>shift = 00</td>
</tr>
<tr>
<td>LSR</td>
<td>shift = 01</td>
</tr>
<tr>
<td>ASR</td>
<td>shift = 10</td>
</tr>
<tr>
<td>ROR</td>
<td>shift = 11</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

**Operation**

```plaintext
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
if invert then operand2 = NOT(operand2);

case op of
  when LogicalOp_AND result = operand1 AND operand2;
  when LogicalOp_ORR result = operand1 OR operand2;
  when LogicalOp_EOR result = operand1 EOR operand2;
if setflags then
  PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
X[d] = result;
```
C6.6.141  ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate register value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate). See the Alias conditions table for details of when each alias is preferred.

| 31 30 29 28|27 26 25 24|23 22 21 | 16|15 | 10 9 | 5 4 | 0 |

C6.6.152   ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the EXTR instruction. This means that:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \) \&\& \( imms = 0xxxxx \).

\[
\text{ROR} <Wd>, <Ws>, \#<shift>
\]

is equivalent to

\[
\text{EXTR} <Wd>, <Ws>, <Ws>, \#<shift>
\]

and is the preferred disassembly when \( Rn == Rm \).

### 64-bit variant

Applies when \( sf = 1 \) \&\& \( N = 1 \).

\[
\text{ROR} <Xd>, <Xs>, \#<shift>
\]

is equivalent to

\[
\text{EXTR} <Xd>, <Xs>, <Xs>, \#<shift>
\]

and is the preferred disassembly when \( Rn == Rm \).

**Assembler symbols**

- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xs>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<\text{shift}>\): For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.
  For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

**Operation**

The description of EXTR gives the operational pseudocode for this instruction.
C6.6.153 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the RORV instruction. This means that:

• The encodings in this description are named to match the encodings of RORV.
• The description of RORV gives the operational pseudocode for this instruction.

32-bit variant
Applies when $sf = 0$.

ROR $<Wd>, <Wn>, <Wm>$
is equivalent to
RORV $<Wd>, <Wn>, <Wm>$
and is always the preferred disassembly.

64-bit variant
Applies when $sf = 1$.

ROR $<Xd>, <Xn>, <Xm>$
is equivalent to
RORV $<Xd>, <Xn>, <Xm>$
and is always the preferred disassembly.

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wn>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

$<Wm>$ Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xn>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

$<Xm>$ Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation
The description of RORV gives the operational pseudocode for this instruction.
C6.6.154   RORV

Rotate Right Variable provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register). The alias is always the preferred disassembly.

X[d] &= \text{result};
\end{align*}
\]
### C6.6.155 SBC

Subtract with Carry subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

This instruction is used by the alias NGC. See the *Alias conditions* table for details of when each alias is preferred.

#### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{SBC} \ less than \ Wd \>, \ <Wn> \>, \ <Wm> \\
\]

#### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{SBC} \ less than \ Xd \>, \ <Xn> \>, \ <Xm> \\
\]

#### Decode for all variants of this encoding

```c
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
```

#### Alias conditions

<table>
<thead>

X[d] = result;
C6.6.157  SBFIZ

Signed Bitfield Insert in Zero zeroes the destination register and copies any number of contiguous bits from a source register into any position in the destination register, sign-extending the most significant bit of the transferred value.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \land N = 0 \).

\[
\text{SBFIZ}<Wd>, <Wn>, #<lsb>, #<width>
\]

is equivalent to

\[
\text{SBFM}<Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
\]

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

### 64-bit variant

Applies when \( sf = 1 \land N = 1 \).

\[
\text{SBFIZ}<Xd>, <Xn>, #<lsb>, #<width>
\]

is equivalent to

\[
\text{SBFM}<Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
\]

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<lsb>\) For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \(<width>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

#### Operation

The description of SBFM gives the operational pseudocode for this instruction.
C6.6.158  SBFM

Signed Bitfield Move copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, shifting in copies of the sign bit in the upper bits and zeros in the lower bits.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW. See the Alias conditions on page C6-682 table for details of when each alias is preferred.

32-bit variant
Applies when $sf = 0 \&\& N = 0$.

$SBFM <Wd>, <Wn>, #<immr>, #<imms>

64-bit variant
Applies when $sf = 1 \&\& N = 1$.

$SBFM <Xd>, <Xn>, #<immr>, #<imms>

Decode for all variants of this encoding

Assembler symbols

<wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<immr> For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field.

For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

<imms> For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.

For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

```c
bits(datasize) dst = if inzero then Zeros() else X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

// determine extension bits (sign, zero or dest register)
bits(datasize) top = if extend then Replicate(src<S>) else dst;

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```
C6.6.159 SBFX

Signed Bitfield Extract extracts any number of adjacent bits at any position from a register, sign-extends them to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf = 0 \&\& N = 0$.

$SBFX <Wd>, <Wn>, #<lsb>, #<width>$

is equivalent to

$SBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)$

and is the preferred disassembly when $BFXPreferred(sf, opc<1>, imms, immr)$.

64-bit variant

Applies when $sf = 1 \&\& N = 1$.

$SBFX <Xd>, <Xn>, #<lsb>, #<width>$

is equivalent to

$SBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)$

and is the preferred disassembly when $BFXPreferred(sf, opc<1>, imms, immr)$.

Assembler symbols

- $<Wd>$: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$: Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- $<Xd>$: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$: Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- $<lsb>$: For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- $<width>$: For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-$<lsb>$.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-$<lsb>$.

Operation

The description of SBFM gives the operational pseudocode for this instruction.
C6.6.160 SDIV

Signed Divide divides a signed integer register value by another signed integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit variant

Applies when sf = 0.

SDIV <Wd>, <Wn>, <Wm>

64-bit variant

Applies when sf = 1.

SDIV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean unsigned = (o1 == '0');

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;
if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero(Int(operand1, unsigned) / Int(operand2, unsigned));
X[d] = result<datasize-1:0>;
C6.6.161   SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see *Wait for Event mechanism and Send event on page D1-1595*.

This instruction is an alias of the HINT instruction. This means that:

- The encodings in this description are named to match the encodings of HINT.
- The description of HINT gives the operational pseudocode for this instruction.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11| 8 | 7 | 5 | 4 | 3 | 2 | 1 | 0]
  1 1 0 1 0 1 0 0 0 0 0 1 1 0 1 0 0 0 0 0 1 1 1 1
```

**System variant**

SEV

is equivalent to

HINT #4

and is always the preferred disassembly.

**Operation**

The description of HINT gives the operational pseudocode for this instruction.
C6.6.162  SEVL

Send Event Local is a hint instruction. It causes an event to be signaled locally without the requirement to affect other PEs in the multiprocessor system. It can prime a wait-loop which starts with a WFE instruction.

This instruction is an alias of the HINT instruction. This means that:

- The encodings in this description are named to match the encodings of HINT.
- The description of HINT gives the operational pseudocode for this instruction.

System variant

SEVL

is equivalent to

HINT #5

and is always the preferred disassembly.

Operation

The description of HINT gives the operational pseudocode for this instruction.
C6.6.163 SMADDL

Signed Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMULL. See the Alias conditions table for details of when each alias is preferred.

```
[31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 16 | 15 | 14 | 10 | 9 | 5 | 4 | 0]
1 0 0 1 1 0 1 1 0 0 1 | Rm | 0 1 1 1 1 1 | Ra | Rn | Rd
U o0
```

64-bit variant

SMADDL <Xd>, <Wn>, <Wm>, <Xa>

**Decode for this encoding**

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- integer m = UInt(Rm);
- integer a = UInt(Ra);
- integer destsize = 64;
- integer datasize = 32;
- boolean sub_op = (o0 == '1');
- boolean unsigned = (U == '1');

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMULL</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

**Assembler symbols**

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- <Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

**Operation**

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;
if sub_op then
  result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
```
result = Int(operand3, unsigned) + (Int(operand1, unsigned) * Int(operand2, unsigned));

X[d] = result<63:0>;
C6.6.164  SMC

Secure Monitor Call causes an exception to EL3.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, using the EC value 0x17, that is taken to EL3. When EL3 is using AArch32, this exception is taken to Monitor mode.

If the value of HCR_EL2.TSC is 1, execution of an SMC instruction in a Non-secure EL1 state generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD. When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information, see Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1573.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- CONSTRAINED UNPREDICTABLE if executed in Secure state at EL1 or higher.

```
[31 30 29 28|27 26 25 24|23 22 21 20] | | | 5 4 3 2 1 0 |
[1 1 0 1 0 1 0 0|0 0 0] imm16 | 0 0 0|1 1
```

System variant

SMC #<imm>

Decode for this encoding

bits(16) imm = imm16;

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

if !HaveEL(EL3) || PSTATE_EL == EL0 then
    UnallocatedEncoding();
AArch64.CheckForSMCTrap(imm);

if SCR_EL3.SMD == '1' then
    // SMC disabled
    AArch64.UndefiedFault();
else
    AArch64.CallSecureMonitor(imm);
C6.6.165 SMNEGL

Signed Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMSUBL instruction. This means that:

• The encodings in this description are named to match the encodings of SMSUBL.
• The description of SMSUBL gives the operational pseudocode for this instruction.

64-bit variant

SMNEGL <Xd>, <Wn>, <Wm>

is equivalent to

SMSUBL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMSUBL gives the operational pseudocode for this instruction.
C6.6.166   SMSUBL

Signed Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL. See the Alias conditions table for details of when each alias is preferred.

64-bit variant
SMSUBL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = 64;
integer datasize = 32;
boolean sub_op = (o0 == '1');

Assembler symbols

<Xd>        Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>        Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>        Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>        Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;
if sub_op then
  result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
\[
\text{result} = \text{Int}\text{(operand3, unsigned)} + (\text{Int}\text{(operand1, unsigned)} \times \text{Int}\text{(operand2, unsigned)})
\]

\[
X[d] = \text{result}<63:0>;
\]
C6.6.167  SMULH

Signed Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

64-bit variant

SMULH <Xd>, <Xn>, <Xm>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);           // ignored by UMULH/SMULH
integer destsize = 64;
integer datasize = destsize;
boolean unsigned = (U == '1');

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

integer result;
result = Int(operand1, unsigned) * Int(operand2, unsigned);
X[d] = result<127:64>;
C6.6.168  SMULL

Signed Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMADDL instruction. This means that:

• The encodings in this description are named to match the encodings of SMADDL.
• The description of SMADDL gives the operational pseudocode for this instruction.

64-bit variant

SMULL  <Xd>, <Wn>, <Wm>

is equivalent to

SMADDL  <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.
C6.6.169 STLR

Store-Release Register stores a 32-bit word or a 64-bit doubleword to a memory location, from a register. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page B2-90. For information about memory accesses see Load/Store addressing modes on page C1-126.

32-bit variant

Applies when size = 10.

STLR <Wt>, [<Xn|SP>{,#0}]

64-bit variant

Applies when size = 11.

STLR <Xt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

            X[t] = ZeroExtend(data, regsize);
### C6.6.172 STLXP

Store-Release Exclusive Pair Of Registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-107. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page B2-90. For information about memory accesses see *Load/Store addressing modes* on page C1-126.

#### 32-bit variant

Applies when \( sz = 0 \).

\[
\text{STLXP} \ <\text{Ws}> , \ <\text{Wt}1> , \ <\text{Wt}2> , \ [<\text{Xn}|\text{SP}>{,#0}]
\]

#### 64-bit variant

Applies when \( sz = 1 \).

\[
\text{STLXP} \ <\text{Ws}> , \ <\text{Xt}1> , \ <\text{Xt}2> , \ [<\text{Xn}|\text{SP}>{,#0}]
\]

#### Decode for all variants of this encoding

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);   // ignored by all loads and store-release

AccType acctype = if o0 == '1' then AccType_ORDERED else AccType_ATOMIC;
boolean pair = TRUE;
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer elsize = 32 << UInt(sz);
integer regsize = if elsize == 64 then 64 else 32;
integer datasize = if pair then elsize * 2 else elsize;
```

#### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors*, and particularly STLXP on page J1-5451.

#### Assembler symbols

- \( <\text{Ws}> \) Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.

- \( <\text{Xt}1> \) Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

- \( <\text{Xt}2> \) Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

- \( <\text{Wt}1> \) Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

\[

STLXRH

Store-Release Exclusive Register Halfword stores a halfword from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-107. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page B2-90. For information about memory accesses see Load/Store addressing modes on page C1-126.

No offset variant

STLXRH <Ws>, <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);   // ignored by all loads and store-release

AccType acctype = if o0 == '1' then AccType_ORDERED else AccType_ATOMIC;  
boolean pair = FALSE; 
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE; 
integer elsize = 8 << UInt(size);  
integer regsize = if elsize == 64 then 64 else 32; 
integer datasize = if pair then elsize * 2 else elsize;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXRH on page J1-5449.

Assembler symbols

<Ws>  Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0   If the operation updates memory.
1   If the operation fails to update memory.

<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.
• <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.
If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<R> Is the index width specifier, encoded in the "option" field. It can have the following values:
  W when option = x10
  X when option = x11
It is reserved when:
  • option = 00x.
  • option = 10x.
<m> Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.
<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
  UXTW when option = 010
  LSL when option = 011
  SXTW when option = 110
SXTX when option = 111

It is reserved when:
  • option = 00x.
  • option = 10x.

For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
  #0 when S = 0
  #2 when S = 1

For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
  #0 when S = 0
  #3 when S = 1

size opc

Unsigned offset variant

STRH <Wt>, [<Xn|SP>{, #<pimm>}

Decode for this encoding

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRH (immediate) on page J1-5448.

Assembler symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- `<pimm>` Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as `<pimm>/2`.

Shared decode for all encodings

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_NORMAL;
MemOp memop;
boolean signed;
integer regsize;
if opc<1> == '0' then
    // store or zero-extending load

C6.6.183  STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an immediate offset, and
stores a halfword from a 32-bit register to the calculated address. For information about memory accesses, see
Load/Store addressing modes on page C1-126.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base
register value and an offset register value. The offset can be optionally shifted and extended.

32-bit variant

STRH <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

Decode for this encoding

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<R> Is the index width specifier, encoded in the "option" field. It can have the following values:
  W  when option = x10
  X  when option = x11

It is reserved when:
•  option = 00x.
•  option = 10x.

<m> Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm"
field.

<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
  UXTW  when option = 010
  LSL   when option = 011
  SXTW  when option = 110
  SXTX  when option = 111

It is reserved when:
•  option = 00x.
•  option = 10x.
Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:

#0 when S = 0
#1 when S = 1

**Shared decode for all encodings**

C6.6.190 STXP

Store Exclusive Pair Of Registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-107. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. For information about memory accesses see Load/Store addressing modes on page C1-126.

integer datasize = if pair then elsize * 2 else elsize;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXP on page J1-5451.

Assembler symbols

- \(<W_s>\) Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.

- \(<X_t1>\) Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

- \(<X_t2>\) Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

- \(<W_t1>\) Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

### Operation

```plaintext

C6.6.192  STXRB

Store Exclusive Register Byte stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-107. The memory access is atomic.

For information about memory accesses see Load/Store addressing modes on page C1-126.

No offset variant

STXRB <Ws>, <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s =UInt(Rs);   // ignored by all loads and store-release

AccType acctype = if o0 == '1' then AccType_ORDERED else AccType_ATOMIC;
boolean pair = FALSE;
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
integer datasize = if pair then elsize * 2 else elsize;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXRB on page J1-5450.

Assembler symbols

<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Ws>  Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0  If the operation updates memory.
1  If the operation fails to update memory.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.
• <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

### No offset variant

STXRH `<Ws>`, `<Wt>`, `[<Xn]|SP>{,#0}]`

### Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);   // ignored by all loads and store-release

AccType accctype = if o0 == '1' then AccType_ORDERED else AccType_ATOMIC;
boolean pair = FALSE;
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
integer datasize = if pair then elsize * 2 else elsize;

### Assembler symbols

 `<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
 0 If the operation updates memory.
 1 If the operation fails to update memory.

 `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

 `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

      data = Mem[address, dbytes, acctype];
      X[t] = ZeroExtend(data, regsize);
C6.6.194  SUB (extended register)

Subtract (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

32-bit variant
Applies when sf = 0.

\[
\text{SUB } <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
\]

64-bit variant
Applies when sf = 1.

\[
\text{SUB } <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
\]

Decode for all variants of this encoding

\[
\begin{array}{cc}
\text{integer } d & = \text{UInt}(Rd); \\
\text{integer } n & = \text{UInt}(Rn); \\
\text{integer } m & = \text{UInt}(Rm); \\
\text{integer } \text{datasize} & = \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{boolean } \text{sub_op} & = (op == '1'); \\
\text{boolean } \text{setflags} & = (S == '1'); \\
\text{ExtendType } \text{extend_type} & = \text{DecodeRegExtend}(\text{option}); \\
\text{integer } \text{shift} & = \text{UInt}(\text{imm3}); \\
\text{if } \text{shift} > 4 \text{ then ReservedValue();}
\end{array}
\]

Assembler symbols

\[
<\text{Wd}|\text{WSP}> \quad \text{Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.}
\]

\[
<\text{Wn}|\text{WSP}> \quad \text{Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.}
\]

\[
<\text{Wm}> \quad \text{Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.}
\]

\[
<\text{Xd}|\text{SP}> \quad \text{Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.}
\]

\[
<\text{Xn}|\text{SP}> \quad \text{Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.}
\]

\[
<R> \quad \text{Is a width specifier, encoded in the "option" field. It can have the following values:}
\]

\[
\begin{array}{ll}
\text{w} & \text{when option = 00x} \\
\text{w} & \text{when option = 010} \\
\text{x} & \text{when option = x11} \\
\text{w} & \text{when option = 10x} \\
\text{w} & \text{when option = 110}
\end{array}
\]
Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTX when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

### Operation

```
basis(result); basis(op1) = if n == 31 then SP[] else X[n]; basis(op2) = ExtendReg(m, extend_type, shift); basis(nzcv); bit carry_in;
if sub_op then
    op2 = NOT(op2);

if d == 31 && !setflags then
  SP[] = result;
else
  X[d] = result;
### C6.6.196   SUB (shifted register)

Subtract (shifted register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias NEG (shifted register). See the Alias conditions table for details of when each alias is preferred.

#### 32-bit variant

Applies when \( sf = 0 \).

```
SUB \(<Wd>, <Wn>, <Wm>{, <shift> #<amount}>)
```

#### 64-bit variant

Applies when \( sf = 1 \).

```
SUB \(<Xd>, <Xn>, <Xm>{, <shift> #<amount}>)
```

#### Decode for all variants of this encoding

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

#### Alias conditions

<table>
<thead>
<tr>
<th>Alias conditions</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEG (shifted register)</td>
<td>( Rn == '11111' )</td>
</tr>
</tbody>
</table>

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10
- It is reserved when shift = 11.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;
bit carry_in;
if sub_op then
    operand2 = NOT(operand2);
carry_in = '1';
else
    carry_in = '0';
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```
C6.6.197 SUBS (extended register)

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register). See the table for details of when each alias is preferred.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{SUBS} \ <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
\]

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{SUBS} \ <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
\]

#### Decode for all variants of this encoding

- \( \text{integer } d = \text{UInt}(Rd) \);
- \( \text{integer } n = \text{UInt}(Rn) \);
- \( \text{integer } m = \text{UInt}(Rm) \);
- \( \text{integer } \text{datasize} = \text{if } sf = '1' \text{ then } 64 \text{ else } 32 \);
- \( \text{boolean } \text{sub_op} = (\text{op} == '1') \);
- \( \text{boolean } \text{setflags} = (S == '1') \);
- \( \text{ExtendType } \text{extend_type} = \text{DecodeRegExtend}(\text{option}) \);
- \( \text{integer } \text{shift} = \text{UInt}(\text{imm3}) \);
- \( \text{if } \text{shift} > 4 \text{ then } \text{ReservedValue}() \);

#### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn|WSP>\) Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn|SP>\) Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R> Is a width specifier, encoded in the "option" field. It can have the following values:

- \text{W} when option = 00x
- \text{W} when option = 010
- \text{X} when option = x11
- \text{W} when option = 10x
- \text{W} when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- \text{UXTB} when option = 000
- \text{UXTH} when option = 001
- \text{LSL|UXTW} when option = 010
- \text{UXTX} when option = 011
- \text{SXTB} when option = 100
- \text{SXTX} when option = 101
- \text{SXTW} when option = 110
- \text{SXTX} when option = 111

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- \text{UXTB} when option = 000
- \text{UXTH} when option = 001
- \text{UXTW} when option = 010
- \text{LSL|UXTX} when option = 011
- \text{SXTB} when option = 100
- \text{SXTX} when option = 101
- \text{SXTW} when option = 110
- \text{SXTX} when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- \text{UXTB} when option = 000
- \text{UXTH} when option = 001
- \text{UXTW} when option = 010
- \text{LSL|UXTX} when option = 011
- \text{SXTB} when option = 100
- \text{SXTX} when option = 101
- \text{SXTW} when option = 110
- \text{SXTX} when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

\textbf{Operation}

\begin{verbatim}
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;
if sub_op then
  operand2 = NOT(operand2);
carry_in = '1';
else
  carry_in = '0';
\end{verbatim}
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
C6.6.198   SUBS (immediate)

Subtract (immediate), setting flags, subtracts an optionally-shifted immediate value from a register value, and writes
the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMP (immediate). See the Alias conditions table for details of when each alias
is preferred.

```
C6.6.200   SVC

Supervisor Call causes an exception to be taken to EL1.

On executing an SVC instruction, the PE records the exception as a Supervisor Call exception, using the EC value 0x15, and the value of the immediate argument. This is reported in:

- ESR_ELx, if the exception is taken to an Exception level that is using AArch64.
- HSR, if the exception is taken to an Exception level that is using AArch32. See Use of the HSR on page G4-4177.

**System variant**

SVC #<imm>

**Decode for this encoding**

bits(16) imm = imm16;

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

AArch64.CallSupervisor(imm);
C6.6.201   SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \&\& N = 0 \).

\[ \text{SXTB } <Wd>, <Wn> \]

is equivalent to

\[ \text{SBFM } <Wd>, <Wn>, #0, #7 \]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \&\& N = 1 \).

\[ \text{SXTB } <Xd>, <Wn> \]

is equivalent to

\[ \text{SBFM } <Xd>, <Xn>, #0, #7 \]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{imm}>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

### Operation

The description of SBFM gives the operational pseudocode for this instruction.
C6.6.202  SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 && N = 0 \).

\[
\text{SXTH } <\text{Wd}>, <\text{Wn}>
\]

is equivalent to

\[
\text{SBFM } <\text{Wd}>, <\text{Wn}>, #0, #15
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 && N = 1 \).

\[
\text{SXTH } <\text{Xd}>, <\text{Wn}>
\]

is equivalent to

\[
\text{SBFM } <\text{Xd}>, <\text{Xn}>, #0, #15
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<\text{Wd}>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Xd}>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{Xn}>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{Wn}>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

### Operation

The description of SBFM gives the operational pseudocode for this instruction.
C6.6.203  SXTW

Sign Extend Word sign-extends a word to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

64-bit variant

SXTW <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #31

and is always the preferred disassembly.

Assembler symbols

- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.
C6.6.204   SYS

System instruction. For more information, see Op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-249 for the encodings of System instructions.

This instruction is used by the aliases AT, DC, IC, and TLBI. See the Alias conditions table for details of when each alias is preferred.

<table>

14-bit signed PC-relative branch offset variant

TBNZ <R><t>, #<imm>, <label>

Decode for this encoding

integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bit bit_val = op;
bits(64) offset = SignExtend(imm14:'00', 64);

Assembler symbols

<R> Is a width specifier, encoded in the "b5" field. It can have the following values:
  W when b5 = 0
  X when b5 = 1
In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

bits(datasize) operand = X[t];

if operand-bit_pos == bit_val then
  BranchTo(PC[] + offset, BranchType_JMP);
C6.6.207  TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

14-bit signed PC-relative branch offset variant
TBZ <R><t>, #<imm>, <label>

Decode for this encoding

integer t = UInt(Rt);
integer datassize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bit bit_val = op;
bots(64) offset = SignExtend(imm14:'00', 64);

Assembler symbols

<R> Is a width specifier, encoded in the "b5" field. It can have the following values:
W when b5 = 0
X when b5 = 1
In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

bits(datassize) operand = X[t];
if operand<bit_pos> == bit_val then
    BranchTo(PC[] + offset, BranchType_JMP);
C6.6.208 TLBI

TLB Invalidate operation. For more information, see A64 system instructions for TLB maintenance on page C5-344.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

### System variant

TLBI \(<\text{tlbi\_op}>\{, <\text{Xt}>\}

is equivalent to

SYS \#<op1>, C8, <Cm>, \#<op2>\{, <Xt>\}

and is the preferred disassembly when \(\text{SysOp}(\text{op1},'1000',\text{CRm},\text{op2}) == \text{Sys\_TLBI}\).

### Assembler symbols

- **<op1>** Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- **<Cm>** Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- **<op2>** Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- **<tlbi\_op>** Is a TLBI operation name, as listed for the TLBI system operation group, encoded in the "op1:CRm:op2" field. It can have the following values:
  - VMALLE1IS when op1 = 000, CRm = 0011, op2 = 000
  - VAE1IS when op1 = 000, CRm = 0011, op2 = 001
  - ASIDE1IS when op1 = 000, CRm = 0011, op2 = 010
  - VAAE1IS when op1 = 000, CRm = 0011, op2 = 011
  - VALE1IS when op1 = 000, CRm = 0011, op2 = 101
  - VALE1 when op1 = 000, CRm = 0011, op2 = 101
  - IPAS2E1IS when op1 = 100, CRm = 0000, op2 = 001
  - IPAS2LE1IS when op1 = 100, CRm = 0000, op2 = 101
  - ALLE2IS when op1 = 100, CRm = 0011, op2 = 001
  - VAE2IS when op1 = 100, CRm = 0011, op2 = 001
  - ALLE1IS when op1 = 100, CRm = 0011, op2 = 100
  - VALE2IS when op1 = 100, CRm = 0011, op2 = 101
VMALLS12E1S when op1 = 100, CRm = 0011, op2 = 110
IPAS2E1  when op1 = 100, CRm = 0100, op2 = 001
IPAS2LE1 when op1 = 100, CRm = 0100, op2 = 101
ALLE2    when op1 = 100, CRm = 0111, op2 = 000
VAE2     when op1 = 100, CRm = 0111, op2 = 001
ALLE1    when op1 = 100, CRm = 0111, op2 = 100
VALE2    when op1 = 100, CRm = 0111, op2 = 101
VMALLS12E1 when op1 = 100, CRm = 0111, op2 = 110
ALLE3IS  when op1 = 110, CRm = 0011, op2 = 000
VAE3IS   when op1 = 110, CRm = 0011, op2 = 001
VALE3IS  when op1 = 110, CRm = 0011, op2 = 101
ALLE3    when op1 = 110, CRm = 0111, op2 = 000
VAE3     when op1 = 110, CRm = 0111, op2 = 001
VALE3    when op1 = 110, CRm = 0111, op2 = 101

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.6.209  TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result: \( Rn \ AND \ imm \)

This instruction is an alias of the ANDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when \( sf = 0 \land N = 0 \).

TST \(<Wn>, #<imm>\)

is equivalent to

ANDS WZR, \(<Wn>, #<imm>\)

and is always the preferred disassembly.

**64-bit variant**

Applies when \( sf = 1 \).

TST \(<Xn>, #<imm>\)

is equivalent to

ANDS XZR, \(<Xn>, #<imm>\)

and is always the preferred disassembly.

**Assembler symbols**

- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<imm>\) Is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

The description of ANDS (immediate) gives the operational pseudocode for this instruction.
C6.6.210 TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ANDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{TST} \ <Wn>, \ <Wm>\{, \ <shift> \ #<amount>\}
\]

is equivalent to

\[
\text{ANDS} \ \text{WZR}, \ <Wn>, \ <Wm>\{, \ <shift> \ #<amount>\}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{TST} \ <Xn>, \ <Xm>\{, \ <shift> \ #<amount>\}
\]

is equivalent to

\[
\text{ANDS} \ \text{XZR}, \ <Xn>, \ <Xm>\{, \ <shift> \ #<amount>\}
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
  - ROR when shift = 11
- \(<\text{amount}>\) is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of **ANDS (shifted register)** gives the operational pseudocode for this instruction.
C6.6.211 UBFIZ

Unsigned Bitfield Insert in Zero zeroes the destination register and copies any number of contiguous bits from a source register into any position in the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

 Applies when \( sf = 0 \land N = 0 \).

\[
\text{UBFIZ} \ <Wd>, \ <Wn>, \ #<lsb>, \ #<width>
\]

is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #(-<lsb> \ mod \ 32), \ #(<width>-1)
\]

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

64-bit variant

 Applies when \( sf = 1 \land N = 1 \).

\[
\text{UBFIZ} \ <Xd>, \ <Xn>, \ #<lsb>, \ #<width>
\]

is equivalent to

\[
\text{UBFM} \ <Xd>, \ <Xn>, \ #(-<lsb> \ mod \ 64), \ #(<width>-1)
\]

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{lsb}>\) For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \(<\text{width}>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<\text{lsb}>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<\text{lsb}>.

Operation

The description of UBFM gives the operational pseudocode for this instruction.
C6.6.212  **UBFM**

Unsigned Bitfield Move copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, with zeros in the upper and lower bits.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH. See the *Alias conditions* on page C6-790 table for details of when each alias is preferred.

**32-bit variant**

Applies when $sf = 0 \&\& N = 0$.

$UBFM <Wd>, <Wn>, #<immr>, #<imms>$

**64-bit variant**

Applies when $sf = 1 \&\& N = 1$.

$UBFM <Xd>, <Xn>, #<immr>, #<imms>$

**Decode for all variants of this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

boolean inzero;
boolean extend;
integer R;
integer S;
bits(datasize) wmask;
bits(datasize) tmask;

case opc of
    when '00' inzero = TRUE; extend = TRUE; // SBFM
    when '01' inzero = FALSE; extend = FALSE; // BFM
    when '10' inzero = TRUE; extend = FALSE; // UBFM
    when '11' UnallocatedEncoding();

    if sf == '1' && N != '1' then ReservedValue();
    if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

    R = UInt(immr);
    S = UInt(imms);
    (wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

- $Wd$ to $Wn$, $Wn$ to $Wd$
- $Xd$ to $Xn$, $Xn$ to $Xd$
- $Xn$ to $Wn$, $Wn$ to $Xn$
- $Xn$ to $Xd$, $Xd$ to $Xn$

---

**Description**

The operation of the UBFM instruction is as follows:

1. **Source and Destination Registers**: The source register $Wd$ is treated as the source of the bitfield, and the destination register $Wn$ is treated as the destination register. The bitfield is extracted from the source register, and the bits are moved to the destination register.
2. **Zero Padding**: Any remaining bits in the destination register are filled with zeros.
3. **Immediate Values**: The immediate value $immr$ defines the number of bits to be moved, and $imms$ defines the starting position of the bitfield.

The UBFM instruction is used to manipulate bitfields, which are sequences of bits where the order is significant. This instruction is particularly useful in scenarios where precise control over the extraction and placement of bitfields is required.

\text{bits(data size)} \text{ top = if extend then \text{Replicate(src<s>s)} else dst;}
\]
\[
\text{// combine extension bits and result bits}
\]
\[
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
\]
C6.6.213 UBFX

Unsigned Bitfield Extract extracts any number of adjacent bits at any position from a register, zero-extends them to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when \( sf = 0 && N = 0 \).

\[
\text{UBFX} \ <Wd>, \ <Wn>, \ #<\text{lsb}>, \ #<\text{width}>
\]

is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #<\text{lsb}>, \ #(<\text{lsb}>+<\text{width}>-1)
\]

and is the preferred disassembly when \( \text{BFXPreferred}(sf, \ opc<1>, \ \text{imms}, \ \text{immr}) \).

**64-bit variant**

Applies when \( sf = 1 && N = 1 \).

\[
\text{UBFX} \ <Xd>, \ <Xn>, \ #<\text{lsb}>, \ #<\text{width}>
\]

is equivalent to

\[
\text{UBFM} \ <Xd>, \ <Xn>, \ #<\text{lsb}>, \ #(<\text{lsb}>+<\text{width}>-1)
\]

and is the preferred disassembly when \( \text{BFXPreferred}(sf, \ opc<1>, \ \text{imms}, \ \text{immr}) \).

**Assembler symbols**

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{lsb}>\) For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- \(<\text{width}>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

**Operation**

The description of UBFM gives the operational pseudocode for this instruction.
C6.6.214   UDIV

Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes
the result to the destination register. The condition flags are not affected.

32-bit variant

Applies when \( sf = 0 \).

UDIV <Wd>, <Wn>, <Wm>

64-bit variant

Applies when \( sf = 1 \).

UDIV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

integer \( d = \text{UInt}(Rd); \)
integer \( n = \text{UInt}(Rn); \)
integer \( m = \text{UInt}(Rm); \)
integer \( \text{datasize} = \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \)
boolean \( \text{unsigned} = (o1 == '0'); \)

Assembler symbols

<Wd>             Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>             Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>             Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>             Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>             Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>             Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) \( \text{operand1} = X[n]; \)
bits(datasize) \( \text{operand2} = X[m]; \)
integer \( \text{result}; \)

if \( \text{IsZero}(\text{operand2}); \) then
result = 0;
else
    result = RoundTowardsZero(\text{Int(operand1, unsigned) / Int(operand2, unsigned)});
\nX[d] = result<datasize-1:0>;
C6.6.215  UMADDL

Unsigned Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL. See the Alias conditions table for details of when each alias is preferred.

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMSUBL gives the operational pseudocode for this instruction.
C6.6.217  UMSUBL

Unsigned Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNEGL. See the Alias conditions table for details of when each alias is preferred.

**64-bit variant**

UMSUBL <Xd>, <Wn>, <Wm>, <Xa>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = 64;
integer datasize = 32;
boolean sub_op = (o0 == '1');
boolean unsigned = (U == '1');

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>UMNEGL</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

**Assembler symbols**

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

**Operation**

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;
if sub_op then
    result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
result = \texttt{Int(operand3, unsigned)} + (\texttt{Int(operand1, unsigned)} \times \texttt{Int(operand2, unsigned)});

X[d] = \texttt{result<63:0>};
C6.6.218   UMULH

Unsigned Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

\[
\begin{array}{cccccccc}
1 & 0 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & \text{Rn} & 0 & 1 & 1 & 1 & 1 & \text{Rn} & \text{Rd} \\

\end{align*}
C6.6.219   UMULL

Unsigned Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMADDL instruction. This means that:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode for this instruction.

### 64-bit variant

UMULL <Xd>, <Wn>, <Wm>

is equivalent to

UMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

### Assembler symbols

- `<Xd>`   Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`   Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Wm>`   Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

### Operation

The description of UMADDL gives the operational pseudocode for this instruction.
C6.6.220   UXTB

Unsigned Extend Byte extracts an 8-bit value from a register, zero-extends it to the size of the register, and writes
the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

• The encodings in this description are named to match the encodings of UBFM.
• The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

UXTB <Wd>, <Wn>

is equivalent to

UBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

Assembler symbols

<Wd>           Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>           Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.
C6.6.221 UXTH

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

UXTH <Wd>, <Wn>

is equivalent to

UBFM <Wd>, <Wn>, #0, #15

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.
C6.6.222 WFE

Wait For Event is a hint instruction that permits the PE to enter a low-power state until one of a number of events occurs, including events signaled by executing the SEV instruction on any PE in the multiprocessor system. For more information, see Wait for Event mechanism and Send event on page D1-1595.

As described in Wait for Event mechanism and Send event on page D1-1595, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1560.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1578.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1586.

This instruction is an alias of the HINT instruction. This means that:

- The encodings in this description are named to match the encodings of HINT.
- The description of HINT gives the operational pseudocode for this instruction.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 | 7 5 | 4 | 3 | 2 | 1 | 0]
  1 1 0 1 0 1 0 0 0 0 0 1 1 0 0 1 0 0 0 0 0 0 1 0 1 1 1 1
  CRm  op2
```

**System variant**

WFE

is equivalent to

HINT #2

and is always the preferred disassembly.

**Operation**

The description of HINT gives the operational pseudocode for this instruction.
C6.6.223   WFI

Wait For Interrupt is a hint instruction that permits the PE to enter a low-power state until one of a number of asynchronous event occurs. For more information, see Wait For Interrupt on page D1-1598.

As described in Wait For Interrupt on page D1-1598, the execution of a WFI instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1560.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1578.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1586.

This instruction is an alias of the HINT instruction. This means that:

- The encodings in this description are named to match the encodings of HINT.
- The description of HINT gives the operational pseudocode for this instruction.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 7 5 4 3 2 1 0 |
|----------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
|    1 1 0 1 0 1 0 0 0 0 0 0 1 1 0 0 1 0 0 0 0 0 0 0 1 1 1 1 1 1 |

CRm   op2
```

**System variant**

WFI

is equivalent to

HINT #3

and is always the preferred disassembly.

**Operation**

The description of HINT gives the operational pseudocode for this instruction.
YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see The YIELD instruction on page B1-67.

This instruction is an alias of the HINT instruction. This means that:

- The encodings in this description are named to match the encodings of HINT.
- The description of HINT gives the operational pseudocode for this instruction.

**System variant**

YIELD is equivalent to HINT #1 and is always the preferred disassembly.

**Operation**

The description of HINT gives the operational pseudocode for this instruction.
Chapter C7
A64 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes the A64 SIMD and floating-point instructions.

It contains the following sections:
• Introduction on page C7-806.
• About the SIMD and floating-point instructions on page C7-807.
• Alphabetical list of floating-point and Advanced SIMD instructions on page C7-809.
C7.1 Introduction

*Alphabetical list of floating-point and Advanced SIMD instructions on page C7-809* is an alphabetical list of instructions that are part of the following two functional groups:

- Loads and store instructions associated with the SIMD and floating-point registers.
- Data processing instructions with SIMD and floating-point registers.

*A64 instruction index by encoding on page C4-184* in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.
C7.2 About the SIMD and floating-point instructions

This section provides a general description of the SIMD and floating-point instructions. It contains the following subsections:

- Register size.
- Data types.
- Condition flags and related instructions on page C7-808.
- General capabilities on page C7-808.

C7.2.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

- A single scalar value of the floating-point or integer type.
- A 64-bit wide vector containing one or more elements.
- A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see Vector formats on page A1-39.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

- Insert vector element from another vector element or general-purpose register, INS.
- Load structure into a single lane, for example LD3.
- All second-part narrowing operations, for example SHRN2.

C7.2.2 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

- Half-precision, single-precision, and double-precision floating points.
- Signed and unsigned integers.
- Polynomials over \{0, 1\}.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

Note

AArch32 Advanced SIMD operations always use ARM standard floating-point arithmetic independent of the FPCR and FPSCR rounding mode. In addition, floating-point multiply-addition operations in AArch64 are always performed as fused operations, whereas AArch32 provides both fused and chained variants.

In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example SHRN2, that can pack the result of a second operation into the upper part of the same destination register.
- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example SMLAL2, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialised head or tail handling, or both.
C7.2.3 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point FCSEL and FCMP instructions are equivalent to the integer CSEL and COMP instructions.
- Floating-point FOMP, FCMPE, FCMPP, and FCMP set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.
- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example FOMPE.

--- Note ---

FOMP and FOMPE differ from the A32/T32 VCMP and VCMPE instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an FOMP or FOMPE operation in the PSTATE.{N, Z, C, V} field.

---

C7.2.4 General capabilities

A64 SIMD and floating-point instructions provide the following capabilities:

- General arithmetic on vector and scalar floating-point and integer values.
- Dedicated polynomial multiply over \{0, 1\}.
- Vector and scalar fused multiply-addition of single-precision and double-precision floating-points.
- Load and store of single and pairs of SIMD and floating-point registers.
- Load and store of structures and individual lanes of between one and four SIMD and floating-point registers.
- Direct conversion between 64-bit integers and floating-point values, with explicit rounding.
- Double-rounding free conversion between double-precision and half-precision floating-point values.
- Comprehensive SIMD with widening and narrowing support.
- Vector to scalar reduction returning the minimum or maximum value, or the sum.
- Floating-point to nearest integer in floating-point format.
C7.3  Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every section in the floating-point and Advanced SIMD categories of the A64 instruction set. For details of the format used, see *Structure of the A64 assembler language* on page C1-121.
C7.3.1   ABS

Absolute value (vector)

Scalar

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10  9 |   5 4 |  0 |
|0 1 1 1 1 0| size 1 0 0 0 0 1 0 1 1 |1 0 |
```

Scalar variant

ABS <V><d>, <V><n>

Decode for this encoding

```java
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean neg = (U == '1');
```

Vector

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10  9 |   5 4 |  0 |
|0 0 1 1 1 0| size 1 0 0 0 0 1 0 1 1 |1 0 |
```

Vector variant

ABS <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```java
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean neg = (U == '1');
```

Assembler symbols

- `<V>`: Is a width specifier, encoded in the "size" field. It can have the following values:
  - D when size = 11
  - 0 when size = 0x
  - 10 when size = 10.
- `<d>`: Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- `<n>`: Is the number of the SIMD&FP source register, encoded in the "Rn" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

It is reserved when size = 11, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```
C7.3.2 ADD (vector)

Add (vector)

**Scalar**

\[
\begin{array}{cccccccccccccccc}
0 & 1 & 0 & 1 & 1 & 1 & 0 & \text{size} & 1 & \text{Rm} & 1 & 0 & 0 & 0 & 1 & \text{Rn} & \text{Rd}
\end{array}
\]

**Scalar variant**

ADD \(\langle V\rangle<\mathbf{d}, \langle V\rangle<\mathbf{n}, \langle V\rangle<\mathbf{m}\rangle\)

**Decode for this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(\text{Rd}); \\
\text{integer } n &= \text{UInt}(\text{Rn}); \\
\text{integer } m &= \text{UInt}(\text{Rm}); \\
\text{if size:\ }&= '11' \text{ then ReservedValue();} \\
\text{integer esize }&= 8 \times \text{UInt(size);} \\
\text{integer datasize }&= \text{esize;} \\
\text{integer elements }&= 1; \\
\text{boolean sub_op }&= (U == '1');
\end{align*}
\]

**Vector**

\[
\begin{array}{cccccccccccccccc}
0 & Q & 0 & 1 & 1 & 1 & 0 & \text{size} & 1 & \text{Rm} & 1 & 0 & 0 & 0 & 1 & \text{Rn} & \text{Rd}
\end{array}
\]

**Vector variant**

ADD \(\langle V\rangle\langle T\rangle, \langle V\rangle\langle n\rangle\langle T\rangle, \langle V\rangle\langle m\rangle\langle T\rangle\)

**Decode for this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(\text{Rd}); \\
\text{integer } n &= \text{UInt}(\text{Rn}); \\
\text{integer } m &= \text{UInt}(\text{Rm}); \\
\text{if size:Q }&= '110' \text{ then ReservedValue();} \\
\text{integer esize }&= 8 \times \text{UInt(size);} \\
\text{integer datasize }&= \text{if Q }== '1' \text{ then 128 else 64;} \\
\text{integer elements }&= \text{datasize DIV esize;} \\
\text{boolean sub_op }&= (U == '1');
\end{align*}
\]

**Assembler symbols**

\(\langle V\rangle\) Is a width specifier, encoded in the "size" field. It can have the following values:

- 0 when size = 11

It is reserved when:

- size = 0x.
- size = 10.

\(\langle d\rangle\) Is the number of the SIMD&FP destination register, in the "Rd" field.

\(\langle n\rangle\) Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(\langle m\rangle\) Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- `8B` when size = 00, Q = 0
- `16B` when size = 00, Q = 1
- `4H` when size = 01, Q = 0
- `8H` when size = 01, Q = 1
- `2S` when size = 10, Q = 0
- `4S` when size = 10, Q = 1
- `2D` when size = 11, Q = 1
- It is reserved when size = 11, Q = 0.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;
V[d] = result;
```
C7.3.3 ADDHN, ADDHN2

Add returning high narrow

Add returning high narrow

Three registers, not all the same type variant

ADDHN<2> <Vd>, <Tb>, <Vn>, <Ta>, <Vm>, <Ta>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

| [absent] | when Q = 0 |
| [present] | when Q = 1 |

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

| 8B   | when size = 00, Q = 0 |
| 16B  | when size = 00, Q = 1 |
| 4H   | when size = 01, Q = 0 |
| 8H   | when size = 01, Q = 1 |
| 2S   | when size = 10, Q = 0 |
| 4S   | when size = 10, Q = 1 |

It is reserved when size = 11, Q = x.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

| 8H   | when size = 00 |
| 4S   | when size = 01 |
| 2D   | when size = 10 |

It is reserved when size = 11.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize)   result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```
C7.3.4 ADDP (scalar)

Add pair of elements (scalar)

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9   |   5   |   4   |   0   |
| 0 1 0 1 1 1 0 | size 1 1 0 0 | 1 1 0 1 1 1 0 | Rd    | Rn    |
```

**Advanced SIMD variant**

```
ADDP <V><d>, <Vn>.<T>
```

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();

integer esize = 8 << UInt(size);
integer datasize = esize * 2;
integer elements = 2;

ReduceOp op = ReduceOp_ADD;
```

**Assembler symbols**

- `<V>` Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - 0 when size = 11
  - It is reserved when:
    - size = 0x.
    - size = 10.

- `<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>` Is the source arrangement specifier, encoded in the "size" field. It can have the following values:
  - 2D when size = 11
  - It is reserved when:
    - size = 0x.
    - size = 10.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(op, operand, esize);
```
### C7.3.5 ADDP (vector)

Add pairwise (vector)

  when '11111'
    // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then UnallocatedEncoding();
    operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

**Assembler symbols**

`<Vd>` Is the name of the SIMD&FP register, encoded in the "Rd" field.

`<T>` For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4H</td>
<td>when Q = 0</td>
</tr>
<tr>
<td>8H</td>
<td>when Q = 1</td>
</tr>
</tbody>
</table>
For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- **2S** when Q = 0
- **4S** when Q = 1

**<imm8>** is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

**<amount>** For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

- 0 when cmode<1> = 0
- 8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

- 0 when cmode<2:1> = 00
- 8 when cmode<2:1> = 01
- 16 when cmode<2:1> = 10
- 24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

**Vector variant**

CNT <Vd>.<T>, <Vn>.<T>

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '00' then ReservedValue();
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `8B` when size = '00', Q = '0'
  - `16B` when size = '00', Q = '1'

It is reserved when:

- size = '01', Q = 'x'.
- size = '1x', Q = 'x'.

- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
  count = BitCount(Elem[operand, e, esize]);
  Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;
```
### C7.3.31 DUP (element)

Duplicate vector element to vector or scalar

This instruction is used by the alias MOV (scalar). The alias is always the preferred disassembly.

#### Scalar

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] 16|15 14 13 12|11 10 9 | 5 4 | 0 |
0 1 0 1 1 1 1 0 0 0 0 | imm5 0 0 0 0 1 | Rd |
```

**Scalar variant**

DUP <V><d>, <Vn>.<T> [<index>]

**Decode for this encoding**

```java
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

integer esize = 8 << size;
integer datasize = esize;
integer elements = 1;
```

#### Vector

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] 16|15 14 13 12|11 10 9 | 5 4 | 0 |
0 Q 0 0 1 1 1 0 0 0 0 | imm5 0 0 0 0 1 | Rd |
```

**Vector variant**

DUP <Vd>.<T>, <Vn>.<Ts>[<index>]

**Decode for this encoding**

```java
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

if size == 3 && Q == '0' then ReservedValue();
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```
Assembler symbols

<T> For the scalar variant: is the element width specifier, encoded in the "imm5" field. It can have the following values:
- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

It is reserved when imm5 = x0000.

For the vector variant: is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:
- 8B when imm5 = xxxx1, Q = 0
- 16B when imm5 = xxxx1, Q = 1
- 4H when imm5 = xxx10, Q = 0
- 8H when imm5 = xxx10, Q = 1
- 2S when imm5 = xx100, Q = 0
- 4S when imm5 = xx100, Q = 1
- 2D when imm5 = x1000, Q = 1

It is reserved when:
- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:
- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

It is reserved when imm5 = x0000.

<V> Is the destination width specifier, encoded in the "imm5" field. It can have the following values:
- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

It is reserved when imm5 = x0000.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index> Is the element index encoded in the "imm5" field. It can have the following values:
- imm5<4:1> when imm5 = xxxx1
- imm5<4:2> when imm5 = xxx10
- imm5<4:3> when imm5 = xx100
- imm5<4> when imm5 = x1000

It is reserved when imm5 = x0000.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bites(idxdsize) operand = V[n];
bites(datasize) result;
bites(esize) element;

element = Elem[operand, index, esize];
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```
C7.3.32  DUP (general)

Duplicate general-purpose register to vector

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 17 16</th>
<th>15 14 13 12</th>
<th>11 10 9</th>
<th>6 5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**Advanced SIMD variant**

DUP <Vd>,<T>,<R><n>

**Decode for this encoding**

```java
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();
// imm5<4:size+1> is IGNORED
if size == 3 && Q == '0' then ReservedValue();
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:
  - 8B when imm5 = xxxx1, Q = 0
  - 16B when imm5 = xxxx1, Q = 1
  - 4H when imm5 = xxx10, Q = 0
  - 8H when imm5 = xxx10, Q = 1
  - 2S when imm5 = xx100, Q = 0
  - 4S when imm5 = xx100, Q = 1
  - 2D when imm5 = x1000, Q = 1

It is reserved when:
- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

- `<R>` Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
  - W when imm5 = xxxx1
  - W when imm5 = xxx10
  - W when imm5 = xx100
  - X when imm5 = x1000

It is reserved when imm5 = x0000.

Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

- `<n>` Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
C7.3.33   EOR (vector)

Bitwise exclusive OR (vector)

Three registers of the same type variant
EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

VBitOp op;

case opc2 of
  when '00' op = VBitOp_VEOR;
  when '01' op = VBitOp_VBSL;
  when '10' op = VBitOp_VBIT;
  when '11' op = VBitOp_VBIF;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  8B when Q = 0
  16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand2;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

case op of
  when VBitOp_VEOR
    operand1 = V[m];
    operand2 = Zeros();
    operand3 = Ones();

operand2 = operand1;
operand3 = V[m];
when VBitOp_VBIF
operand1 = V[d];
operand2 = operand1;
operand3 = NOT(V[m]);

V[d] = operand1 EOR ((operand2 EOR operand4) AND operand3);
C7.3.34 EXT

Extract vector from pair of vectors

```
[31 30 29 28|27 26 25 24|23 22 21 20]| 16|15 14 | 11 10 9 | 5 4 | 0 |
0 | Q | 1 0 1 1 0 0 0 | Rm | 0 | imm4 | 0 | Rn | Rd |
```

**Advanced SIMD variant**

EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>

**Decode for this encoding**

```
integer d = UInt(Rd);
n = UInt(Rn);
m = UInt(Rm);
if Q == '0' && imm4<3> == '1' then UnallocatedEncoding();
datasize = if Q == '1' then 128 else 64;
position = UInt(imm4) << 3;
```

**Assembler symbols**

- `<Vd>`: Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>`: Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- `<Vn>`: Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>`: Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<index>`: Is the lowest numbered byte element to be extracted, encoded in the "Q:imm4" field. It can have the following values:
  - imm4<2:0> when Q = 0, imm4<3> = 0
  - imm4 when Q = 1, imm4<3> = x

It is reserved when Q = 0, imm4<3> = 1.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m];
b bits(datasize) lo = V[n];
bits(datasize+2) concat = hi : lo;
V[d] = concat<position:datasize-1:position>;
```

```

Assembler symbols

<\V>   Is a width specifier, encoded in the "immh" field. It can have the following values:

 S     when immh = 01xx
 D     when immh = 1xxx
It is reserved when immh = 00xx.

<\d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\d>
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<\T>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when:
- immh = 0001, Q = x.
- immh = 001x, Q = x.
- immh = 1xxx, Q = 0.

<\n>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<\fbits>
For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:

- \((64-\text{UInt}(\text{immh:immb}))\) when immh = 01xx
- \((128-\text{UInt}(\text{immh:immb}))\) when immh = 1xxx

It is reserved when immh = 00xx.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:

- \((64-\text{UInt}(\text{immh:immb}))\) when immh = 01xx
- \((128-\text{UInt}(\text{immh:immb}))\) when immh = 1xxx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when:
- immh = 0001.
- immh = 001x.

C7.3.85   FDIV (vector)

Floating-point divide (vector)

Three registers of the same type variant

FDIV <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
  - 2S when sz = 0, Q = 0
  - 4S when sz = 0, Q = 1
  - 2D when sz = 1, Q = 1
  - It is reserved when sz = 1, Q = 0.
- `<Vn>` is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPDiv(element1, element2, FPCR);
V[d] = result;
```
C7.3.86   FDIV (scalar)

Floating-point divide (scalar) : Vd = Vn / Vm

Single-precision variant

Applies when type = 00.
FDIV <Sd>, <Sn>, <Sm>

Double-precision variant

Applies when type = 01.
FDIV <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

Assembler symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
result = FPDiv(operand1, operand2, FPCR);
V[d] = result;
C7.3.87 FMADD

Floating-point fused multiply-add (scalar): \( V_d = V_a + V_n \times V_m \)

<table>
<thead>

Assembler symbols

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
  S when sz = 0
  D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
  2S when Q = 0, sz = 0
  4S when Q = 1, sz = 0
  2D when Q = 1, sz = 1
  It is reserved when Q = 0, sz = 1.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> For the scalar variant: is the name of the SIMD&FP source register, encoded in the "M:Rm" fields.
     For the vector variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

<Ts> For the scalar variant: is the element width specifier, encoded in the "sz" field. It can have the following values:
  S when sz = 0
  D when sz = 1

For the vector variant: is an element size specifier, encoded in the "sz" field. It can have the following values:
  S when sz = 0
  D when sz = 1

<index> For the scalar variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:
  H:L when sz = 0, L = x
  H when sz = 1, L = 0
  It is reserved when sz = 1, L = 1.

For the vector variant: is the element index encoded in the "sz:L:H" field. It can have the following values:
  H:L when sz = 0, L = x
  H when sz = 1, L = 0
  It is reserved when sz = 1, L = 1.

- \(<S_m>\) Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bias(datasize) result;
bias(datasize) operand1 = V[n];
bias(datasize) operand2 = V[m];

if sub_op then
  result = FPSub(operand1, operand2, FPCR);
else
  result = FPAdd(operand1, operand2, FPCR);
V[d] = result;
```
C7.3.150 INS (element)

Insert vector element from another vector element

This instruction is used by the alias MOV (element). The alias is always the preferred disassembly.

Advanced SIMD variant

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<3:size>);
integer idxdsize = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

<table>
<thead>
<tr>
<th>Spec</th>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>xxxx1</td>
</tr>
<tr>
<td>H</td>
<td>xxx10</td>
</tr>
<tr>
<td>S</td>
<td>xx100</td>
</tr>
<tr>
<td>D</td>
<td>x1000</td>
</tr>
</tbody>
</table>

It is reserved when imm5 = x0000.

<index1> Is the destination element index encoded in the "imm5" field. It can have the following values:

<table>
<thead>
<tr>
<th>Index</th>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>imm5&lt;4:1&gt;</td>
<td>when imm5 = xxxx1</td>
</tr>
<tr>
<td>imm5&lt;4:2&gt;</td>
<td>when imm5 = xxx10</td>
</tr>
<tr>
<td>imm5&lt;4:3&gt;</td>
<td>when imm5 = xx100</td>
</tr>
<tr>
<td>imm5&lt;4&gt;</td>
<td>when imm5 = x1000</td>
</tr>
</tbody>
</table>

It is reserved when imm5 = x0000.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index2> Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

<table>
<thead>
<tr>
<th>Index</th>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>imm4&lt;3:0&gt;</td>
<td>when imm5 = xxxx1</td>
</tr>
<tr>
<td>imm4&lt;3:1&gt;</td>
<td>when imm5 = xxx10</td>
</tr>
<tr>
<td>imm4&lt;3:2&gt;</td>
<td>when imm5 = xx100</td>
</tr>
<tr>
<td>imm4&lt;3&gt;</td>
<td>when imm5 = x1000</td>
</tr>
</tbody>
</table>
It is reserved when imm5 = x0000.
Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation

    CheckFPAdvSIMDEnabled64();
    bits(idxdsize) operand = V[n];
    bits(128) result;

    result = V[d];
    Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
    V[d] = result;
C7.3.151 INS (general)

Insert vector element from general-purpose register

This instruction is used by the alias MOV (from general). The alias is always the preferred disassembly.

<table>
<thead>
<tr>
<th>31 30 29 28</th>

<td>0 0 0 1 1</td>
<td>Rn</td>
<td>Rd</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Advanced SIMD variant

INS <Vd>.<Ts>[<index>], <R><n>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();
integer index = UInt(imm5<4:size+1>);

integer esize = 8 << size;
integer datasize = 128;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1
H when imm5 = xxx10
S when imm5 = xx100
D when imm5 = x1000

It is reserved when imm5 = x0000.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1> when imm5 = xxxx1
imm5<4:2> when imm5 = xxx10
imm5<4:3> when imm5 = xx100
imm5<4> when imm5 = x1000

It is reserved when imm5 = x0000.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

W when imm5 = xxxx1
W when imm5 = xxx10
W when imm5 = xx100
X when imm5 = x1000

It is reserved when imm5 = x0000.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;

result = V[d];
Elem[result, index, esize] = element;
V[d] = result;
C7.3.152   LD1 (multiple structures)

Load multiple 1-element structures to one, two, three or four registers

No offset

One register variant
Applies when opcode = 0111.
LD1 { <Vt>.<T> }, [<Xn|SP>]

Two registers variant
Applies when opcode = 1010.
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

Three registers variant
Applies when opcode = 0110.
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]

Four registers variant
Applies when opcode = 0010.
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]

Decode for all variants of this encoding

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;

Post-index

One register, immediate offset variant
Applies when Rm = 11111 && opcode = 0111.
LD1 { <Vt>.<T> }, [<Xn|SP>], <imm>

One register, register offset variant
Applies when Rm != 11111 && opcode = 0111.
LD1 { <Vt>.<T> }, [<Xn|SP>], <Xm>

Two registers, immediate offset variant
Applies when Rm = 11111 && opcode = 1010.
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>

Two registers, register offset variant
Applies when \( Rm \neq 11111 \) \& \( \text{opcode} = 1010 \).

LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

Three registers, immediate offset variant
Applies when \( Rm = 11111 \) \& \( \text{opcode} = 0110 \).

LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>

Three registers, register offset variant
Applies when \( Rm \neq 11111 \) \& \( \text{opcode} = 0110 \).

LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>

Four registers, immediate offset variant
Applies when \( Rm = 11111 \) \& \( \text{opcode} = 0010 \).

LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>

Four registers, register offset variant
Applies when \( Rm \neq 11111 \) \& \( \text{opcode} = 0010 \).

LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>

Decode for all variants of this encoding

integer \( t = \text{UInt}(Rt) \);
integer \( n = \text{UInt}(Rn) \);
integer \( m = \text{UInt}(Rm) \);
boolean wback = TRUE;

Assembler symbols

\(<Vt>\) is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

\(<T>\) is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when \( \text{size} = 00 \), \( Q = 0 \)
- 16B when \( \text{size} = 00 \), \( Q = 1 \)
- 4H when \( \text{size} = 01 \), \( Q = 0 \)
- 8H when \( \text{size} = 01 \), \( Q = 1 \)
- 2S when \( \text{size} = 10 \), \( Q = 0 \)
- 4S when \( \text{size} = 10 \), \( Q = 1 \)
- 1D when \( \text{size} = 11 \), \( Q = 0 \)
- 2D when \( \text{size} = 11 \), \( Q = 1 \)

\(<Vt2>\) is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\(<Vt3>\) is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

\(<Vt4>\) is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

\(<Xn>|SP>\) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #8 when Q = 0
- #16 when Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #16 when Q = 0
- #32 when Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #24 when Q = 0
- #48 when Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #32 when Q = 0
- #64 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

### Shared decode for all encodings

LD3 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>

**Decode for all variants of this encoding**

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

**Assembler symbols**

- `<Vt>` is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<T>` is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
C7.3 Alphabetical list of floating-point and Advanced SIMD instructions

2D when size = 11, Q = 1
It is reserved when size = 11, Q = 0.

<vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
- #24 when Q = 0
- #48 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

integer m = UInt(Rm);
boolean wback = TRUE;

Assembler symbols

<Vt>    Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<T>    Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B      when size = 00, Q = 0
16B     when size = 00, Q = 1
4H      when size = 01, Q = 0
8H      when size = 01, Q = 1
2S      when size = 10, Q = 0
4S      when size = 10, Q = 1
1D when size = 11, Q = 0
2D when size = 11, Q = 1

\(<Vt2>\) Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\(<Vt3>\) Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

\(<Vt4>\) Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\(<imm>\) Is the post-index immediate offset, encoded in the "size" field. It can have the following values:
- #4 when size = 00
- #8 when size = 01
- #16 when size = 10
- #32 when size = 11

\(<Xm>\) Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

  if sub_op then
\texttt{Elem[result, e, esize] = Elem[operand3, e, esize] - product;}
\texttt{else}
\texttt{Elem[result, e, esize] = Elem[operand3, e, esize] + product;}

\texttt{V[d] = result;
C7.3.174 MOV (scalar)

Move vector element to scalar

This instruction is an alias of the DUP (element) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode for this instruction.

Scalar variant

MOV <V><d>, <Vn>.<T>[<index>]

is equivalent to

DUP <V><d>, <Vn>.<T>[<index>]

and is always the preferred disassembly.

Assembler symbols

<
> Is the destination width specifier, encoded in the "imm5" field. It can have the following values:
B  when imm5 = xxxx1
H  when imm5 = xxx10
S  when imm5 = xx100
D  when imm5 = x1000

It is reserved when imm5 = x0000.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the element width specifier, encoded in the "imm5" field. It can have the following values:
B  when imm5 = xxxx1
H  when imm5 = xxx10
S  when imm5 = xx100
D  when imm5 = x1000

It is reserved when imm5 = x0000.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1>  when imm5 = xxxx1
imm5<4:2>  when imm5 = xxx10
imm5<4:3>  when imm5 = xx100
imm5<4>    when imm5 = x1000

It is reserved when imm5 = x0000.

Operation

The description of DUP (element) gives the operational pseudocode for this instruction.
C7.3.175   MOV (element)

Move vector element to another vector element

This instruction is an alias of the INS (element) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (element).
- The description of INS (element) gives the operational pseudocode for this instruction.

### Advanced SIMD variant

MOV \(<V_d>.<Ts>[<index_1>], <V_n>.<Ts>[<index_2>]\)

is equivalent to

INS \(<V_d>.<Ts>[<index_1>], <V_n>.<Ts>[<index_2>]\)

and is always the preferred disassembly.

### Assembler symbols

\(<V_d>\)

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<Ts>\)

Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- **B** when \(imm5 = xxxx1\)
- **H** when \(imm5 = xxx10\)
- **S** when \(imm5 = xx100\)
- **D** when \(imm5 = x1000\)

It is reserved when \(imm5 = x0000\).

\(<index_1>\)

Is the destination element index encoded in the "imm5" field. It can have the following values:

- \(imm5<4:1>\) when \(imm5 = xxxx1\)
- \(imm5<4:2>\) when \(imm5 = xxx10\)
- \(imm5<4:3>\) when \(imm5 = xx100\)
- \(imm5<4>\) when \(imm5 = x1000\)

It is reserved when \(imm5 = x0000\).

\(<V_n>\)

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<index_2>\)

Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

- \(imm4<3:0>\) when \(imm5 = xxxx1\)
- \(imm4<3:1>\) when \(imm5 = xxx10\)
- \(imm4<3:2>\) when \(imm5 = xx100\)
- \(imm4<3>\) when \(imm5 = x1000\)

It is reserved when \(imm5 = x0000\).

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.
Operation

The description of INS (element) gives the operational pseudocode for this instruction.
C7.3.176 MOV (from general)

Move general-purpose register to a vector element

This instruction is an alias of the INS (general) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (general).
- The description of INS (general) gives the operational pseudocode for this instruction.

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 | 0 |  |
| 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | imm5 | 0 | 0 | 1 | 1 | Rn | Rd |
```

**Advanced SIMD variant**

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

INS <Vd>.<Ts>[<index>], <R><n>

and is always the preferred disassembly.

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ts>` Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - `B` when `imm5 = xxxx1`
  - `H` when `imm5 = xxx10`
  - `S` when `imm5 = xx100`
  - `D` when `imm5 = x1000`
  - It is reserved when `imm5 = x0000`.
- `<index>` Is the element index encoded in the "imm5" field. It can have the following values:
  - `imm5<4:1>` when `imm5 = xxxx1`
  - `imm5<4:2>` when `imm5 = xxx10`
  - `imm5<4:3>` when `imm5 = xx100`
  - `imm5<4>` when `imm5 = x1000`
  - It is reserved when `imm5 = x0000`.
- `<R>` Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
  - `W` when `imm5 = xxxx1`
  - `W` when `imm5 = xxx10`
  - `W` when `imm5 = xx100`
  - `X` when `imm5 = x1000`
  - It is reserved when `imm5 = x0000`.
- `<n>` Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.
Operation

The description of INS (general) gives the operational pseudocode for this instruction.
C7.3.177  MOV (vector)

Move vector

This instruction is an alias of the **ORR (vector, register)** instruction. This means that:

- The encodings in this description are named to match the encodings of **ORR (vector, register)**.
- The description of **ORR (vector, register)** gives the operational pseudocode for this instruction.

### Three registers of the same type variant

**MOV <Vd>.<T>, <Vn>.<T>**

is equivalent to

**ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>**

and is the preferred disassembly when \( Rm == Rn \).

#### Assembler symbols

- **<Vd>**  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<T>**  Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - **8B**  when \( Q = 0 \)
  - **16B**  when \( Q = 1 \)
- **<Vn>**  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

#### Operation

The description of **ORR (vector, register)** gives the operational pseudocode for this instruction.
C7.3.178   MOV (to general)

Move vector element to general-purpose register

This instruction is an alias of the UMOV instruction. This means that:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( Q = 0 \).

\[
\text{MOV} \ <Wd>, \ <Vn>.S[<index>]
\]

is equivalent to

\[
\text{UMOV} \ <Wd>, \ <Vn>.S[<index>]
\]

and is the preferred disassembly when \( \text{imm5} = \text{\'xx100\'} \).

### 64-bit variant

Applies when \( Q = 1 \).

\[
\text{MOV} \ <Xd>, \ <Vn>.D[<index>]
\]

is equivalent to

\[
\text{UMOV} \ <Xd>, \ <Vn>.D[<index>]
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- \(<\text{index}>\) For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:
  - \(\text{imm5<4:1>}\) when \(\text{imm5} = \text{xxxx1}\)
  - \(\text{imm5<4:2>}\) when \(\text{imm5} = \text{xxx10}\)
  - \(\text{imm5<4:3>}\) when \(\text{imm5} = \text{xx100}\)
  - It is reserved when \(\text{imm5} = \text{xx000}\).

For the 64-bit variant: is the element index encoded in "imm5<4>".

### Operation

The description of UMOV gives the operational pseudocode for this instruction.
C7.3.179  MOVI

Move immediate (vector)

type m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

**Assembler symbols**

- **<Vd>** Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<T>** Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1

  It is reserved when:
  - size = 00, Q = x.
  - size = 11, Q = x.

- **<Vn>** Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- **<Vm>** Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
  - 0:Rm when size = 01
  - 0:Rm when size = 10

  It is reserved when:
  - size = 00.
  - size = 11.

Restricted to V0-V15 when element size <Ts> is H.
<Ts>
Is an element size specifier, encoded in the "size" field. It can have the following values:

- `H` when size = 01
- `S` when size = 10

It is reserved when:
- size = 00.
- size = 11.

@index>
Is the element index encoded in the "size:L:H:M" field. It can have the following values:

- `H:L:M` when size = 01

</thead>
<tbody>
<tr>
<td>0</td>
<td>Q</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**Vector variant**

NEG <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

**Assembler symbols**

\(<V>\) Is a width specifier, encoded in the "size" field. It can have the following values:

- D when size = 11
- It is reserved when:
  - size = 0x.
  - size = 10.

\(<d>\) Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\(<n>\) Is the number of the SIMD&FP source register, encoded in the "Rn" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- `8B` when size = 00, Q = 0
- `16B` when size = 00, Q = 1
- `4H` when size = 01, Q = 0
- `8H` when size = 01, Q = 1
- `2S` when size = 10, Q = 0
- `4S` when size = 10, Q = 1
- `2D` when size = 11, Q = 1

It is reserved when size = 11, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```
C7.3.185   NOT

Bitwise NOT (vector)

This instruction is used by the alias MVN. The alias is always the preferred disassembly.

Vector variant

NOT <Vd>.<T>, <Vn>.<T>

_decode for this encoding_

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements - 1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = NOT(element);

V[d] = result;
### C7.3.186  ORN (vector)

Bitwise inclusive OR NOT (vector)

```
    [31 30 29 28][27 26 25 24][23 22 21 20][19 18 17 16][15 14 13 12][11 10 9][ 8][ 7][ 6][ 5][ 4][ 3][ 2][ 1][ 0]
   0 | Q | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | Rm | 0 | 0 | 0 | 1 | 1 | Rn | Rd |
```

**Three registers of the same type variant**

ORN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean invert = (size<0> == '1');
LogicalOp op = if size<1> == '1' then LogicalOp_ORR else LogicalOp_AND;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND
        result = operand1 AND operand2;
    when LogicalOp_ORR
        result = operand1 OR operand2;

V[d] = result;
```
C7.3.187  ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate)

16-bit variant

Applies when cmode = 10x1.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit variant

Applies when cmode = 0xx1.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
```

```
case cmode:op of
  when '0xx00' operation = ImmediateOp_MOVI;
  when '0xx01' operation = ImmediateOp_MVNI;
  when '0xx10' operation = ImmediateOp_ORR;
  when '0xx11' operation = ImmediateOp_BIC;
  when '10x00' operation = ImmediateOp_MOVI;
  when '10x01' operation = ImmediateOp_MVNI;
  when '10x10' operation = ImmediateOp_ORR;
  when '10x11' operation = ImmediateOp_BIC;
  when '110x0' operation = ImmediateOp_MOVI;
  when '110x1' operation = ImmediateOp_MVNI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11110' operation = ImmediateOp_MOVI;
  when '11111'
    // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then UnallocatedEncoding();
    operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

- `<Vd>` is the name of the SIMD&FP register, encoded in the "Rd" field.
- `<T>` is the arrangement specifier, encoded in the "Q" field. It can have the following values:
  - `4H` when `Q = 0`
  - `8H` when `Q = 1`
For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

25 when Q = 0
45 when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

0 when cmode<1> = 0
8 when cmode<1> = 1
defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

0 when cmode<2:1> = 00
8 when cmode<2:1> = 01
16 when cmode<2:1> = 10
24 when cmode<2:1> = 11
defaulting to 0 if LSL is omitted.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
when ImmediateOp_MOVI
  result = imm;
when ImmediateOp_MVNI
  result = NOT(imm);
when ImmediateOp_ORR
  operand = V[rd];
  result = operand OR imm;
when ImmediateOp_BIC
  operand = V[rd];
  result = operand AND NOT(imm);

V[rd] = result;
C7.3.188  **ORR (vector, register)**

Bitwise inclusive OR (vector, register)

This instruction is used by the alias **MOV (vector)**. See the *Alias conditions* table for details of when each alias is preferred.

Three registers of the same type variant

ORR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer part = UInt(Q);
integer elements = datasize DIV esize;

Assembler symbols

2               Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent]       when Q = 0
[present]      when Q = 1

<Vd>            Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta>            Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H              when size = 00
1Q              when size = 11

It is reserved when:

• size = 01.
• size = 10.

The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

<Vn>            Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb>            Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B              when size = 00, Q = 0
16B             when size = 00, Q = 1
1D              when size = 11, Q = 0
2D              when size = 11, Q = 1

It is reserved when:

• size = 01, Q = x.
• \text{size} = 10, Q = x.

Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

boolean round = (op == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when immh = 1xx, Q = x.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<shift> Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

### Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

**Advanced SIMD variant**

SADDLV <V><d>, <Vn>.<T>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

**Assembler symbols**

- `<V>` Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - `H` when size = 00
  - `S` when size = 01
  - `D` when size = 10

  It is reserved when size = 11.

- `<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `8B` when size = 00, Q = 0
  - `16B` when size = 00, Q = 1
  - `4H` when size = 01, Q = 0
  - `8H` when size = 01, Q = 1
  - `4S` when size = 10, Q = 1

  It is reserved when:
  - size = 10, Q = 0.
  - size = 11, Q = x.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
```
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;}

Assembler symbols

<\V> Is a width specifier, encoded in the "immh" field. It can have the following values:

S when immh = 01xx
D when immh = 1xxx
It is reserved when immh = 00xx.

<do>
Is the number of the SIMD&FP destination register, in the "Rd" field.
</do>

<n>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
</n>

<d> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when:
• immh = 0001, Q = x.
• immh = 001x, Q = x.
• immh = 1xxx, Q = 0.

<n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
</n>

<fbits>
For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx

It is reserved when immh = 00xx.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when:
• immh = 0001.
• immh = 001x.

Operation for all encodings

| 0 | Q | 0 | 1 | 1 | 1 | 0 | !=0000 | immh | 0 | 1 | 0 | 1 | 0 | 1 | Rn | Rd |
```

Vector variant

SHL <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if imm == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer shift = UInt(immh:immb) - esize;
```

Assembler symbols

<\V> Is a width specifier, encoded in the "immh" field. It can have the following values:

D when immh = 1xx
It is reserved when immh = 0xx.

<\d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:
- (UInt(immh:immb)-64) when immh = 1xxx
It is reserved when immh = 0xxx.
For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx
- (UInt(immh:immb)-64) when immh = 1xxx
See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
for e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);
V[d] = result;
C7.3.223  SHLL, SHLL2

Shift left long (by element size)

```
[31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 16 | 15 14 13 12 | 11 10 9  |  5 4  |  0  ]
0 | Q | 1 | 0 | 1 | 1 | 0 | size | 1 | 0 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | Rn | Rd
```

**Vector variant**

SHLL(2) <Vd>,<Ta>, <Vn>,<Tb>, #<shift>

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 *< UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE; // Or TRUE without change of functionality
```

**Assembler symbols**

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have
the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

It is reserved when size = 11.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

It is reserved when size = 11, Q = x.
<shift> Is the left shift amount, which must be equal to the source element width in bits, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

It is reserved when size = 11.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;
for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;
V[d] = result;
```

C7.3.224 SHRN, SHRN2

</tbody>
</table>

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x. It is reserved when immh = 1xx, Q = x.

\(<Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<Ta>\) Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

<table>
<thead>
<tr>
<th>\text{8H}</th>
<th>\text{4S}</th>
<th>\text{2D}</th>
</tr>
</thead>
<tbody>
<tr>
<td>when \text{immh} = 0001</td>
<td>when \text{immh} = 001x</td>
<td>when \text{immh} = 01xx</td>
</tr>
</tbody>
</table>

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<shift>
Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:
(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx
See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
### C7.3.225  SHSUB

Signed halving subtract

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer shift = UInt(immh:immb) - esize;
```

**Assembler symbols**

<\V>   Is a width specifier, encoded in the "immh" field. It can have the following values:

D       when immh = 1xx
It is reserved when immh = 0xx.

<\d>   Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n>   Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\d>   Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:

- $(\text{UInt}(\text{immh:immb})-64)$ when immh = 1xxx
- It is reserved when immh = 0xxx.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- $(\text{UInt}(\text{immh:immb})-8)$ when immh = 0001
- $(\text{UInt}(\text{immh:immb})-16)$ when immh = 001x
- $(\text{UInt}(\text{immh:immb})-32)$ when immh = 01xx
- $(\text{UInt}(\text{immh:immb})-64)$ when immh = 1xxx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
bits(datasize) result;
bits(esize) mask = LSL(Ones(esize), shift);
bits(esize) shifted;

for e = 0 to elements-1
    shifted = LSL(Elem[operand, e, esize], shift);
    Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
V[d] = result;
```

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>

Is an arrangement specifier, encoded in the "size" field. It can have the following values:

4S when size = 01
2D when size = 10

It is reserved when:

• size = 00.
• size = 11.

<Vn>

Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

It is reserved when:

• size = 00, Q = x.
• size = 11, Q = x.

<Va>

Is the destination width specifier, encoded in the "size" field. It can have the following values:

S when size = 01
D when size = 10

It is reserved when:

• size = 00.
• size = 11.

<d>

Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<vb>

Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10

It is reserved when:

• size = 00.
• size = 11.

<n>

Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<vm>

Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

0:Rm when size = 01
M:Rm when size = 10
It is reserved when:
  • size = 00.
  • size = 11.
Restricted to V0-V15 when element size <Ts> is H.

<Ts>
For the scalar variant: is the element width specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
  • size = 00.
  • size = 11.
For the vector variant: is an element size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
  • size = 00.
  • size = 11.

@index>
For the scalar variant: is the element index, encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10
It is reserved when:
  • size = 00.
  • size = 11.
For the vector variant: is the element index encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10
It is reserved when:
  • size = 00.
  • size = 11.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<\vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<\Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

4S when size = 01
2D when size = 10

It is reserved when:

• size = 00.
• size = 11.

<\Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<\Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

It is reserved when:

• size = 00, Q = x.
• size = 11, Q = x.

<\Va> Is the destination width specifier, encoded in the "size" field. It can have the following values:

S when size = 01
D when size = 10

It is reserved when:

• size = 00.
• size = 11.

<\d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<\Vb> Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10

It is reserved when:

• size = 00.
• size = 11.

<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

0:Rm when size = 01
M:Rm when size = 10

It is reserved when:

• size = 00.
• size = 11.
Restricted to V0-V15 when element size <Ts> is H.

<Ts> For the scalar variant: is the element width specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
• size = 00.
• size = 11.

For the vector variant: is an element size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
• size = 00.
• size = 11.

<index> For the scalar variant: is the element index, encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10
It is reserved when:
• size = 00.
• size = 11.

For the vector variant: is the element index encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10
It is reserved when:
• size = 00.
• size = 11.

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
• size = 00.
• size = 11.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
It is reserved when:
• size = 00, Q = x.
• size = 11, Q = x.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
0:Rm when size = 01
M:Rm when size = 10
It is reserved when:
• size = 00.
• size = 11.
Restricted to V0-V15 when element size <Ts> is H.

<Ts> For the scalar variant: is the element width specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
• size = 00.
• size = 11.

For the vector variant: is an element size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10
It is reserved when:
  • size = 00.
  • size = 11.

<index>

For the scalar variant: is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

It is reserved when:
  • size = 00.
  • size = 11.

For the vector variant: is the element index encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

It is reserved when:
  • size = 00.
  • size = 11.

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
integer element1;
integer element2;
integer product;
boolean sat;

element2 = SInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
  element1 = SInt(Elem[operand1, e, esize]);
  product = (2 * element1 * element2) + round_const;
  // The following only saturates if element1 and element2 equal -2^(esize-1)
  (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
  if sat then FPSR.QC = '1';

V[d] = result;
```

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
   [absent] when Q = 0
   [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
   8B   when immh = 0001, Q = 0
   16B  when immh = 0001, Q = 1
   4H   when immh = 001x, Q = 0
   8H   when immh = 001x, Q = 1
   2S   when immh = 01xx, Q = 0
   4S   when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = x.

<Rn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
   8H   when immh = 0001
   4S   when immh = 001x
   2D   when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<Vb>  Is the destination width specifier, encoded in the "immh" field. It can have the following values:
   B    when immh = 0001
   H    when immh = 001x
   S    when immh = 01xx

It is reserved when:
   • immh = 0000.
   • immh = 1xxx.

<d>   Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>  Is the source width specifier, encoded in the "immh" field. It can have the following values:
   H    when immh = 0001
   S    when immh = 001x
   D    when immh = 01xx

It is reserved when:
   • immh = 0000.
   • immh = 1xxx.

<n>   Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:
   (16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

It is reserved when:
- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.
