### Assembler symbols

2  
Is the second and upper half specifier. If present it causes the operation to be performed on the upper  
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have  
the following values:

- **[absent]** when \( Q = 0 \)
- **[present]** when \( Q = 1 \)

<\( V_d \)>  
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<\( T_b \)>  
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- **8B** when \( \text{immh} = 0001 \) and \( Q = 0 \)
- **16B** when \( \text{immh} = 0001 \) and \( Q = 1 \)
- **4H** when \( \text{immh} = 0011 \) and \( Q = 0 \)
- **8H** when \( \text{immh} = 0011 \) and \( Q = 1 \)
- **2S** when \( \text{immh} = 01xx \) and \( Q = 0 \)
- **4S** when \( \text{immh} = 01xx \) and \( Q = 1 \)

See Advanced SIMD modified immediate on page C4-217 when \( \text{immh} = 0000 \), \( Q = x \).

It is reserved when \( \text{immh} = 1xxx \), \( Q = x \).

<\( V_n \)>  
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<\( T_a \)>  
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- **8H** when \( \text{immh} = 0001 \)
- **4S** when \( \text{immh} = 0011 \)
- **2D** when \( \text{immh} = 01xx \)

See Advanced SIMD modified immediate on page C4-217 when \( \text{immh} = 0000 \).

It is reserved when \( \text{immh} = 1xxx \).

<\( V_b \)>  
Is the destination width specifier, encoded in the "immh" field. It can have the following values:

- **B** when \( \text{immh} = 0001 \)
- **H** when \( \text{immh} = 0011 \)
- **S** when \( \text{immh} = 01xx \)

It is reserved when:

- \( \text{immh} = 0000 \)
- \( \text{immh} = 1xxx \)

<\( d \)>  
Is the number of the SIMD&FP destination register, in the "Rd" field.

<\( V_a \)>  
Is the source width specifier, encoded in the "immh" field. It can have the following values:

- **H** when \( \text{immh} = 0001 \)
- **S** when \( \text{immh} = 0011 \)
- **D** when \( \text{immh} = 01xx \)

It is reserved when:

- \( \text{immh} = 0000 \)
- \( \text{immh} = 1xxx \)

<\( n \)>  
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\( \text{shift} \)>  
For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in  
bits, encoded in the "immh:immb" field. It can have the following values:

\((16-\text{UInt}(\text{immh}:\text{immb}))\) when \( \text{immh} = 0001 \)
Operation for all encodings

boolean round = (op == '1');
```

**Assembler symbols**

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = x.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:
- B when immh = 0001
- H when immh = 001x
- S when immh = 01xx

It is reserved when:
- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
- H when immh = 0001
- S when immh = 001x
- D when immh = 01xx

It is reserved when:
- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:
- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

It is reserved when:
- immh = 0000.
- immh = 1xxx.
For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

Assembler symbols

<V>  Is a width specifier, encoded in the "immh" field. It can have the following values:
    D    when immh = 1xxx
    It is reserved when immh = 0xxx.
<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- **8B** when immh = 0001, Q = 0
- **16B** when immh = 0001, Q = 1
- **4H** when immh = 001x, Q = 0
- **8H** when immh = 001x, Q = 1
- **2S** when immh = 01xx, Q = 0
- **4S** when immh = 01xx, Q = 1
- **2D** when immh = 1xxx, Q = 1

See *Advanced SIMD modified immediate* on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = 0.

</n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:

- \((128-\text{UInt}(\text{immh}:\text{immb}))\) when immh = 1xxx
- It is reserved when immh = 0xxx.

For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \((16-\text{UInt}(\text{immh}:\text{immb}))\) when immh = 0001
- \((32-\text{UInt}(\text{immh}:\text{immb}))\) when immh = 001x
- \((64-\text{UInt}(\text{immh}:\text{immb}))\) when immh = 01xx
- \((128-\text{UInt}(\text{immh}:\text{immb}))\) when immh = 1xxx

See *Advanced SIMD modified immediate* on page C4-217 when immh = 0000.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx
See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Tb>  Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when immh = 1xxx, Q = x.

<shift>  Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

Operation

CheckFPAdvSIMDEnabled64();

**Decode for all variants of this encoding**

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;

**Assembler symbols**

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 1D when size = 11, Q = 0
- 2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

<Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#8  when Q = 0
#16 when Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#16  when Q = 0
#32  when Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#24  when Q = 0
#48  when Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#32  when Q = 0
#64  when Q = 1

<Xm>  Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

Assembler symbols

<Bt> Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Dt> Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Ht> Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Qt> Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<St> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<R> Is the index width specifier, encoded in the "option" field. It can have the following values:
\[ \begin{array}{ll}
R & \text{when option = x10} \\
X & \text{when option = x11} \\
\end{array} \]
It is reserved when:
\[ \begin{array}{ll}
& \text{option = 00x.} \\
& \text{option = 10x.} \\
\end{array} \]

<m> Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the "option" field. It can have the following values:
\[ \begin{array}{ll}
\text{UXTW} & \text{when option = 010} \\
\text{LSL} & \text{when option = 011} \\
\text{SXTW} & \text{when option = 110} \\
\text{SXTX} & \text{when option = 111} \\
\end{array} \]
It is reserved when:
\[ \begin{array}{ll}
& \text{option = 00x.} \\
& \text{option = 10x.} \\
\end{array} \]

<amount> For the 8-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
\[ \begin{array}{ll}
\text{[absent]} & \text{when } S = 0 \\
#0 & \text{when } S = 1 \\
\end{array} \]
For the 16-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
\[ \begin{array}{ll}
#0 & \text{when } S = 0 \\
#1 & \text{when } S = 1 \\
\end{array} \]
For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
\[ \begin{array}{ll}
#0 & \text{when } S = 0 \\
#2 & \text{when } S = 1 \\
\end{array} \]
For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
\[ \begin{array}{ll}
#0 & \text{when } S = 0 \\
#3 & \text{when } S = 1 \\
\end{array} \]
For the 128-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the "S" field. It can have the following values:
\[ \begin{array}{ll}
#0 & \text{when } S = 0 \\
#4 & \text{when } S = 1 \\
\end{array} \]

- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1
- It is reserved when size = 11, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.3.291  SXTL

Signed extend long

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

• The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
• The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

Vector variant

SXTL{2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8H when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
25 when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when immh = 1xxx, Q = x.
Operation

The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

**Three registers, not all the same type variant**

UADDL(2) <Vd>, <Ta>, <Vn>, <Tb>, <Vm>, <Tb>

**Decode for this encoding**

```plaintext
define integer d = UInt(Rd);
define integer n = UInt(Rn);
define integer m = UInt(Rm);
if size == '11' then ReservedValue();
define integer esize = 8 << UInt(size);
define integer datasize = 64;
define integer part = UInt(Q);
define integer elements = datasize DIV esize;

define boolean sub_op = (o1 == '1');
define boolean unsigned = (U == '1');
```

**Assembler symbols**

- **<Vd>** Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Ta>** Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  - 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
  - It is reserved when size = 11.
- **<Vn>** Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- **<Tb>** Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8H when size = 00, Q = 0
  - 16H when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
  - It is reserved when size = 11, Q = x.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand1 = Vpart[n, part];
bias(datasize) operand2 = Vpart[m, part];
bias(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;

**Assembler symbols**

<\V>  Is a width specifier, encoded in the "immh" field. It can have the following values:

S  when immh = 01xx
D  when immh = 1xxx
It is reserved when immh = 00xx.

\(<d>\) Is the number of the SIMD&FP destination register, in the "Rd" field.

\(<n>\) Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(</d>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<T>\) Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See \textit{Advanced SIMD modified immediate on page C4-217} when immh = 0000, Q = x.

It is reserved when:

- immh = 0001, Q = x.
- immh = 001x, Q = x.
- immh = 1xxx, Q = 0.

\(</n>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<fbits>\) For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:

- (64-UInt(immh:immb)) when immh = 01xx
- (128-UInt(immh:immb)) when immh = 1xxx

It is reserved when immh = 00xx.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:

- (64-UInt(immh:immb)) when immh = 01xx
- (128-UInt(immh:immb)) when immh = 1xxx

See \textit{Advanced SIMD modified immediate on page C4-217} when immh = 0000.

It is reserved when:

- immh = 0001.
- immh = 001x.

2  

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- **[absent]** when Q = 0
- **[present]** when Q = 1

<Vd>  

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  

Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- **4S** when size = 01
- **2D** when size = 10

It is reserved when:

- size = 00.
- size = 11.

<Vn>  

Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>  

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **4H** when size = 01, Q = 0
- **8H** when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

It is reserved when:
• size = 00, Q = x.
• size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
0:Rm when size = 01
M:Rm when size = 10

It is reserved when:
• size = 00.
• size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10

It is reserved when:
• size = 00.
• size = 11.

<index> Is the element index encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10

It is reserved when:
• size = 00.
• size = 11.

Operation

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = x.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx

It is reserved when:
• immh = 0000.
• immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx

It is reserved when:
• immh = 0000.
• immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

It is reserved when:
- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

### Operation for all encodings

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>

Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.
It is reserved when immh = 1xxx, Q = x.

<Vn>

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>

Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

<Vb>

Is the destination width specifier, encoded in the "immmh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx
It is reserved when:
• immh = 0000.
• immh = 1xxx.

<d>

Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>

Is the source width specifier, encoded in the "immmh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx
It is reserved when:
• immh = 0000.
• immh = 1xxx.

<n>

Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift>

For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

It is reserved when:
- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:
(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.
It is reserved when immh = 1xxx.

**Operation for all encodings**

**Assembler symbols**

- `<V>`
  - Is a width specifier, encoded in the "size" field. It can have the following values:
    - 0 when size = 11
  - It is reserved when:
    - size = 0x.
    - size = 10.
- `<db>`
  - Is the number of the SIMD&FP destination register, in the "Rd" field.
<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- `8B` when size = 00, Q = 0
- `16B` when size = 00, Q = 1
- `4H` when size = 01, Q = 0
- `8H` when size = 01, Q = 1
- `2S` when size = 10, Q = 0
- `4S` when size = 10, Q = 1
- `2D` when size = 11, Q = 1
- It is reserved when size = 11, Q = 0.

<n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1); // 0 for left shift, 2^(n-1) for right shift
        element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
        else
            Elem[result, e, esize] = element<esize-1:0>;
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when immh = 1xxx, Q = x.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;

    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```
C7.3.345  UXTL

Unsigned extend long

This instruction is an alias of the USHLL, USHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

```
| 31 30 29 28 | 27 26 25 24 | 23 22 | 19 18 | 16 15 14 13 | 12 | 11 | 9 | 5 | 4 | 0 |
|-------------|-------------|-------------|-------------|-------------|------------------|-------------|
| 0 | Q | 1 | 0 | 1 | 1 | 1 | 0 | !=0000 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | Rn | Rd |
```

Vector variant

UXTL(2) <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

USHLL(2) <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>

Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-217 when immh = 0000.

It is reserved when immh = 1xxx.

<Vn>

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>

Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 88 when immh = 0001, Q = 0
- 168 when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 25 when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-217 when immh = 0000, Q = x.

It is reserved when immh = 1xxx, Q = x.
Operation

The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

The AArch64 System Level Architecture
Chapter D1
The AArch64 System Level Programmers’ Model

This chapter describes the AArch64 system level programmers’ model. It contains the following sections:

• Exception levels on page D1-1490.
• Exception terminology on page D1-1491.
• Execution state on page D1-1493.
• Security state on page D1-1494.
• Virtualization on page D1-1496.
• Registers for instruction processing and exception handling on page D1-1499.
• Process state, PSTATE on page D1-1506.
• Program counter and stack pointer alignment on page D1-1509.
• Reset on page D1-1511.
• Exception entry on page D1-1516.
• Exception return on page D1-1533.
• The Exception level hierarchy on page D1-1538.
• Synchronous exception types, routing and priorities on page D1-1545.
• Asynchronous exception types, routing, masking and priorities on page D1-1552.
• Configurable instruction enables and disables, and trap controls on page D1-1558.
• System calls on page D1-1593.
• Mechanisms for entering a low-power state on page D1-1595.
• Self-hosted debug on page D1-1601.
• The Performance Monitors Extension on page D1-1603.
• Interprocessing on page D1-1604.
• The effect of implementation choices on the programmers’ model on page D1-1616.
D1.1 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers’ model on page D1-1616 shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the system control registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. The ARMv8-A security model on page D1-1494 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter D4 The AArch64 Virtual Memory System Architecture.

D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

- **EL0**: Applications.
- **EL1**: OS kernel and associated functions that are typically described as privileged.
- **EL2**: Hypervisor.
- **EL3**: Secure monitor.
D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

- Terminology for taking an exception.
- Terminology for returning from an exception.
- Exception levels.
- Definition of a precise exception.
- Definitions of synchronous and asynchronous exceptions on page D1-1492.

D1.2.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is taken from. The PE state immediately after taking the exception is the state the exception is taken to.

D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state the exception returns to.

D1.2.3 Exception levels

An Exception level, ELₙ, with a larger value of n than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of n than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
- Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

D1.2.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 LDM and STM instructions and the AArch64 LDP and STP instructions.

Note

- For the definition of a single-copy atomic access, see Single-copy atomicity on page B2-81.
- SError interrupts are known as Asynchronous Aborts in AArch32 state.
- By definition, all synchronous aborts are precise.
D1.2.5 Definitions of synchronous and asynchronous exceptions

An exception is described as synchronous if all of the following apply:

• The exception is generated as a result of direct execution or attempted execution of an instruction.
• The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
• The exception is precise.

For more information about synchronous exceptions, see Synchronous exception types, routing and priorities on page D1-1545.

An exception is described as asynchronous if any of the following apply:

• The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
• The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
• The exception is imprecise.

For more information about asynchronous exceptions, see Asynchronous exception types, routing, masking and priorities on page D1-1552.
D1.3 Execution state

The Execution states are:

AArch64  The 64-bit Execution state.
AArch32  The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

Execution state on page A1-35 gives more information about them.

Exception levels use Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

Note

- Typical Exception level usage model on page D1-1490 shows which Exception levels different software layers might typically use.
- The effect of implementation choices on the programmers’ model on page D1-1616 gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called interprocessing. Interprocessing on page D1-1604 describes this.
D1.4 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

**Secure state**  When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

**Non-secure state**  When in this state, the PE:

- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About the Virtual Memory System Architecture (VMSA)* on page D4-1726.

D1.4.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.

- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

Security model when EL3 is using AArch64

Figure D1-1 on page D1-1495 shows the security model when EL3 is using AArch64. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.
Figure D1-1 ARMv8-A security model when EL3 is using AArch64

For an overview of the Security model when EL3 is using AArch32, see Figure G1-1 on page G1-3816.
### D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine comprises Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems. A Guest OS runs on a virtual machine in Non-secure EL1.
- For each Guest operating system, applications, that run on the virtual machine of that Guest OS, usually in Non-secure EL0.

#### Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a virtual machine identifier (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See Configurable instruction enables and disables, and trap controls on page D1-1558.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent translation regime for memory accesses from EL2.
- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the Virtual Address (VA) to an Intermediate Physical Address (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the Physical Address (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter D4 The AArch64 Virtual Memory System Architecture.

#### D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. EL2 configurable controls on page D1-1567, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

Hypervisor call exceptions taken from EL3 are taken to EL3. Otherwise, Hypervisor call exceptions are taken from Non-secure state to EL2.
All virtual interrupts are always taken to Non-secure EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See Virtual interrupts.

When a virtual interrupt is enabled, in Non-secure state its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see Asynchronous exception types, routing, masking and priorities on page D1-1552.

An implementation that includes EL2 also:

• Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  — Routing exceptions to EL2 on page D1-1546.
  — Routing debug exceptions on page D2-1627.

• Provides mechanisms to trap Non-secure PE operations to EL2. See EL2 configurable controls on page D1-1567.

  When an operation is trapped to EL2, the hypervisor typically either:
  — Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  — Returns an error to the Guest OS.

Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table D1-1.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>Virtual SError</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing in EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example D1-1 shows a usage model for virtual interrupts.

Example D1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   • If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   • If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

A hypervisor can prevent Non-secure EL1 and Non-secure EL0 from distinguishing a virtual interrupt from a physical interrupt.
For more information see:

- *Asynchronous exception types, routing, masking and priorities* on page D1-1552.
- *Virtual interrupts* on page D1-1555.
D1.6 Registers for instruction processing and exception handling

In the ARM architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in Chapter D7 AArch64 System Register Descriptions.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

- The general purpose registers, R0-R30.
- The stack pointer registers.
- The SIMD and floating-point registers, V0-V31 on page D1-1500.
- Saved Program Status Registers (SPSRs) on page D1-1500.
- Exception Link Registers (ELRs) on page D1-1505.

D1.6.1 The general purpose registers, R0-R30

The general purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See Register size on page C6-399.

For information on the format of these registers, see Registers in AArch64 state on page B1-61.

D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- SP_EL0 and SP_EL1.
- If the implementation includes EL2, SP_EL2.
- If the implementation includes EL3, SP_EL3.

Note

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see Special-purpose registers on page C5-264.

For information on stack pointer alignment restrictions, see Stack pointer alignment checking on page D1-1510.

Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, SP_EL0.

When executing at any other Exception level, the PE can be configured to use either SP_EL0 or the stack pointer for that Exception level, SP_ELx.

By default, taking an exception selects the stack pointer for the target Exception level, SP_ELx. For example, taking an exception to EL1 selects SP_EL1. Software executing at the target Exception level can then choose to change the stack pointer to SP_EL0 by updating PSTATE.SP.

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the SP_EL0 stack pointer, then on taking an exception that targets EL1, the stack pointer changes to SP_EL1.

The selected stack pointer can be indicated by a suffix to the Exception level:

- t Indicates use of the SP_EL0 stack pointer.
- h Indicates use of the SP_ELx stack pointer.
Note
The t and h suffixes are based on the terminology of thread and handler, introduced in ARMv7-M.

Table D1-2 shows the set of stack pointer options.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>AArch64 stack pointer options</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>EL0t</td>
</tr>
<tr>
<td>EL1</td>

</tr>
<tr>
<td>EL2</td>
<td>EL2t, EL2h</td>
</tr>
<tr>
<td>EL3</td>
<td>EL3t, EL3h</td>
</tr>
</tbody>
</table>

**D1.6.3 The SIMD and floating-point registers, V0-V31**

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:
- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see *Registers in AArch64 state on page B1-61.*

**D1.6.4 Saved Program Status Registers (SPSRs)**

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:

- **SPSR_EL1**, for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, **SPSR_EL2**, for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, **SPSR_EL3**, for exceptions taken to EL3 using AArch64.

Note
Exceptions cannot be taken to EL0.

When the PE takes an exception, the PE state is saved from PSTATE in the SPSR at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, the PE state is saved in SPSR_EL1. For more information on PSTATE, see *Process state, PSTATE on page D1-1506.*

Saving the PE state means the exception handler can:

- On return from the exception, restore the PE state to the state stored in the SPSR at the Exception level the exception is returning from. For example, on returning from EL1, the PE state is restored to the state stored in SPSR_EL1.
- Examine the value that PSTATE had when the exception was taken, for example to determine the Execution state and Exception level in which the instruction that caused an Undefined Instruction exception was executed.
### Note

- All PSTATE fields are saved, including those which have no direct read and write access, and those that are meaningful only in AArch32 state.
- Those PSTATE fields that are meaningful only in AArch32 state are saved when an exception is taken from AArch32 state to AArch64 state.

The SPSRs are UNKNOWN on reset.

### SPSR format for exceptions taken to AArch64 state

Exceptions can be taken to AArch64 state from AArch64 state or AArch32 state:

- For an exception taken to AArch64 state from AArch64 state, the SPSR bit assignments are:

```
| 31 | 30 | 29 | 28 | 27 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | RES0 | RES0 | RES0 | D | A | I | F | 0 | M[3:0] |
```

Condition flags

- M[4], Execution State
- SS

- Mask bits

- Mode bits

- For an exception taken to AArch64 state from AArch32 state, the SPSR bit assignments are:

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
```

Condition flags

- IT[1:0], Mode bits
- SS

- Mask bits

- Mode bits

The following list describes the bit assignments:

#### N, Z, C, V, bits[31:28]

Shows the values of the PSTATE. \{N, Z, C, V\} condition flags immediately before the exception was taken.

#### Bits[27:22]

Reserved, RES0, for exceptions taken from AArch64 state.

For exceptions taken from AArch32 state:

- **Q**, bit [27]
  
  Shows the value of `PSTATE.Q` immediately before the exception was taken.

- **IT[1:0]**, bits [26:25]
  

- **J**, bit [24]
  
  Shows the value of `PSTATE.J` immediately before the exception was taken. This bit is RES0.

For the definitions of the Q, IT, and J fields, see Process state, PSTATE on page G1-3832.

#### SS, bit[21]

The Software Step bit.

- **SPSR_ELx.SS** is used by a debugger to initiate a Software Step exception. The SS bit also indicates which software step state machine state the PE was in. See Software Step exceptions on page D2-1671.

#### IL, bit[20]

Illegal Execution State bit. Shows the value of `PSTATE.IL` immediately before the exception was taken. See Illegal return events from AArch64 state on page D1-1534.
Bits[19:10]  Reserved, RES0, for exceptions taken from AArch64 state.

For exceptions taken from AArch32 state:

GE[3:0], bits [19:16]
Shows the value of PSTATE.GE immediately before the exception was taken.

IT[7:2], bits [15:10]
In conjunction with IT[1:0], shows the value of PSTATE.IT before the exception was taken.

For definitions of the GE and IT fields, see Process state, PSTATE on page G1-3832.

Bit[9]  D, the debug exception mask bit, for exceptions taken from AArch64 state. Shows the value of PSTATE.D immediately before the exception was taken. See The PSTATE debug mask bit, D on page D1-1601.

E, for exceptions taken from AArch32 state. Shows the value of PSTATE.E immediately before the exception was taken. For the definition of the E bit, see Process state, PSTATE on page G1-3832.

A, I, F, bits[8:6]
Shows the values of the PSTATE. {A,I, F} exception mask bits immediately before the exception was taken:

See Asynchronous exception masking on page D1-1553.

Bit[5]  Reserved, RES0, for exceptions taken from AArch64 state.

T, for exceptions taken from AArch32 state. Shows the value of PSTATE.T Execution state bit immediately before the exception was taken. For the definition of the T bit, see Process state, PSTATE on page G1-3832.

M[4:0], bits[4:0]
Mode field.

Note
The name of this field is inherited from ARMv7, where the M field specified the PE mode.

For exceptions taken from AArch64 state:

M[3:0]  Encodes the Exception level and the stack pointer register selection, as shown in Table D1-3.

Table D1-3 M[3:0] encodings, for exceptions taken from AArch64 state

<table>
<thead>
<tr>
<th>M[3:0](^a)</th>
<th>Exception level and stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1101</td>
<td>EL3h</td>
</tr>
<tr>
<td>0b1100</td>
<td>EL3t</td>
</tr>
<tr>
<td>0b1001</td>
<td>EL2h</td>
</tr>
<tr>
<td>0b1000</td>
<td>EL2t</td>
</tr>
<tr>
<td>0b0101</td>
<td>EL1h</td>
</tr>
<tr>
<td>0b0100</td>
<td>EL1t</td>
</tr>
<tr>
<td>0b0000</td>
<td>EL0t</td>
</tr>
</tbody>
</table>

\(^a\) All M[3:0] encodings not shown in the table are reserved.
The M[3:0] encoding comprises:

- **M[3:2]** Encodes the Exception level, 0-3.
- **M[1]** Reserved, RES0. If set to 1 at the time of an exception return, then that exception return is treated as an Illegal Execution State Exception Return.
- **M[0]** Selects the SP:
  - 0 SP_EL0. Indicated by a t suffix on the Exception level.
  - 1 SP_ELx, where x is the value of M[3:2]. Indicated by an h suffix on the Exception level.

See [Stack pointer register selection](#) on page D1-1499.

For exceptions taken from AArch32 state:

- **M[4]** The value of this is 1. M[4] encodes the value of PSTATE.nRW.
- **M[3:0]** Encodes the AArch32 mode that the PE was in immediately before the exception was taken, as shown in Table D1-4.

### Table D1-4 M[3:0] encodings, for exceptions taken from AArch32 state

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>AArch32 mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Bits [27:22] and [19:10] of an SPSR are ignored on an exception return to AArch64 state. Bits [23:22] of an SPSR are ignored on an exception return to AArch32 state.

### Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs. The SPSR[] function accesses the current SPSR, and is common to AArch32 and AArch64 operations.

```plaintext
// SPSR[] - non-assignment form
// =============================

bits(32) SPSR[]
bits(32) result;
if UsingAArch32() then
  case PSTATE.M of
    when M32_FIQ       result = SPSR_fiq;
    when M32_IRQ        result = SPSR_irq;
    when M32_Svc        result = SPSR_svc;
    when M32_Monitor    result = SPSR_mon;
    when M32_Abort      result = SPSR_abt;
    when M32_Hyp        result = SPSR_hyp;
    when M32_Undef      result = SPSR_und;
    otherwise            Unreachable();
  endcase;
else
  case PSTATE.EL of
    when EL1             result = SPSR_EL1;
    when EL2             result = SPSR_EL2;
    when EL3             result = SPSR_EL3;
    otherwise            Unreachable();
  endcase;
endif;
```
return result;

// SPSR[] - assignment form
// ================

SPSR[] = bits(32) value
if UsingAArch32() then
case PSTATE.M of
  when M32_FIQ     SPSR_fiq = value;
  when M32_IRQ      SPSR_irq = value;
  when M32_Svc      SPSR_svc = value;
  when M32_Monitor  SPSR_mon = value;
  when M32_Abort    SPSR_abt = value;
  when M32_Hyp      SPSR_hyp = value;
  when M32_Undef    SPSR_und = value;
  otherwise        Unreachable();
else
case PSTATE.EL of
  when EL1          SPSR_EL1 = value;
  when EL2          SPSR_EL2 = value;
  when EL3          SPSR_EL3 = value;
  otherwise        Unreachable();

return;

The SetPSTATEFromPSR() function updates PSTATE from an SPSR.

// SetPSTATEFromPSR()  
// ================

SetPSTATEFromPSR(bits(32) spsr)
SynchronizeContext();

PSTATE.SS = DebugExceptionReturnSS(spsr);

if IllegalExceptionReturn(spsr) then
  PSTATE.IL = '1';
else
  // State that is reinstated only on a legal exception return
  PSTATE.IL = spsr<20>;
  if spsr<4> == '1' then                  // AArch32 state
    AArch32.WriteMode(spsr<4:0>);       // Sets PSTATE.EL correctly
  else                                    // AArch64 state
    PSTATE.nRW = '0';
    PSTATE.EL  = spsr<3:2>;
    PSTATE.SP  = spsr<8>;

  // If PSTATE.IL is set and returning to AArch32 state, it is CONSTRAINED UNPREDICTABLE whether
  // the IT and T bits are each set to zero or copied from SPSR. This can be either because the
  // exception return was illegal or because SPSR[20] was set to 1.
  if PSTATE.IL == '1' then
    if ConstrainUnpredictableBool() then spsr<26:25,15:10> = Zeros();
    if ConstrainUnpredictableBool() then spsr<5> = '0';

  // State that is reinstated regardless of illegal exception return
  PSTATE.<N,Z,C,V> = spsr<31:28>;
  if PSTATE.nRW == '1' then               // AArch32 state
    PSTATE.Q         = spsr<27>;
    PSTATE.IT        = spsr<15:10,26:25>;
    PSTATE.GE        = spsr<19:16>;
    PSTATE.E         = spsr<9>;
    PSTATE.<A,I,F>   = spsr<8:6>;         // No PSTATE.<D> in AArch32 state
    PSTATE.T         = spsr<5>;           // PSTATE.J is RES0
  else                                    // AArch64 state
    PSTATE.<D,A,I,F> = spsr<9:6>;         // No PSTATE.<Q,IT,GE,E,T> in AArch64 state

D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in ELR_EL1.

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in ELR_EL1.

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:

- ELR_EL1, for exceptions taken to EL1.
- If EL2 is implemented, ELR_EL2, for exceptions taken to EL2.
- If EL3 is implemented, ELR_EL3, for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see Preferred exception return address on page D1-1516.
D1.7 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:
- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState. The definition of ProcState is:

```plaintext
type ProcState is (
    bits (1) N, // Negative condition flag
    bits (1) Z, // Zero condition flag
    bits (1) C, // Carry condition flag
    bits (1) V, // Overflow condition flag
    bits (1) D, // Debug mask bit [AArch64 only]
    bits (1) A, // Asynchronous abort mask bit
    bits (1) I, // IRQ mask bit
    bits (1) F, // FIQ mask bit
    bits (1) SS, // Software step bit
    bits (1) IL, // Illegal execution state bit
    bits (2) EL, // Exception Level
    bits (1) nRW, // not Register Width: 0=64, 1=32
    bits (1) SP, // Stack pointer select: 0=SP0, 1=SPx [AArch64 only]
    bits (1) Q, // Cumulative saturation flag [AArch32 only]
    bits (4) GE, // Greater than or Equal flags [AArch32 only]
    bits (8) IT, // If-then bits, RES0 in CPSR [AArch32 only]
    bits (1) J, // J bit, RES0 [AArch32 only, RES0 in SPSR and CPSR]
    bits (1) T, // T32 bit, RES0 in CPSR [AArch32 only]
    bits (1) E, // Endianness bit [AArch32 only]
    bits (5) M // Mode field [AArch32 only]
)
```

The fields that are meaningful in AArch64 state are:

### The condition flags

- **N**  Negative Condition flag.
- **Z**  Zero Condition flag.
- **C**  Carry Condition flag.
- **V**  Overflow Condition flag.

*Process state, PSTATE on page B1-64* gives more information about these flags.

### The Execution state controls

- **SS**  Software Step bit. See *Software Step exceptions on page D2-1671*. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- **IL**  Illegal Execution State bit. See *The Illegal Execution State exception on page D1-1536*. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- **nRW** Current Execution state. See *Execution state on page D1-1493*. This bit is 0 when the current Execution state is AArch64. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- **EL**  Current Exception level. See *Exception levels on page D1-1490*. On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level.

**Note**

The ARM architecture requires that a PE resets into the highest implemented Exception level.
SP

Stack pointer register selection bit. See Stack pointer register selection on page D1-1499. On a reset or taking an exception to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected.

The exception mask bits

D

Debug exception mask bit. See The PSTATE debug mask bit, D on page D1-1601. On a reset or taking an exception to AArch64 state, this bit is set to 1.

A, I, F

Asynchronous exception mask bits:

A
SError interrupt mask bit.

I
IRQ interrupt mask bit.

F
FIQ interrupt mask bit.

See Asynchronous exception types, routing, masking and priorities on page D1-1552. On a reset or taking an exception to AArch64 state, each of these bits is set to 1.

D1.7.1 Accessing PSTATE fields

In AArch64 state, PSTATE fields can be accessed using the Special-purpose registers. The Special-purpose registers can be directly read using the MRS instruction, and directly written using the MSR (register) instructions. Table D1-5 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. All other PSTATE fields do not have direct read and write access.

Table D1-5 Accessing PSTATE fields using MRS and MSR (register)

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>DAIF</td>
<td>D, A, I, F</td>
</tr>
<tr>
<td>CurrentEL</td>
<td>EL</td>
</tr>
<tr>
<td>SPSel</td>
<td>SP</td>
</tr>
</tbody>
</table>

Software can also use the MSR (immediate) instruction to directly write to PSTATE. {D, A, I, F, SP}. Table D1-6 shows the MSR (immediate) operands that can directly write to these PSTATE fields when the PE is in AArch64 state.

Table D1-6 Accessing PSTATE.{D, A, I, F, SP} using MSR (immediate)

<table>
<thead>
<tr>
<th>Operand</th>
<th>PSTATE fields</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAIFSet</td>
<td>D, A, I, F</td>
<td>Directly sets any of the PSTATE. {D, A, I, F} bits to 1</td>
</tr>
<tr>
<td>DAIFClr</td>
<td>D, A, I, F</td>
<td>Directly clears any of the PSTATE. {D, A, I, F} bits to 0</td>
</tr>
<tr>
<td>SPSel</td>
<td>SP</td>
<td>Directly sets PSTATE.SP to either 1 or 0</td>
</tr>
</tbody>
</table>

PSTATE. {N, Z, C, V} can be accessed at EL0. Access to PSTATE. {D, A, I, F} at EL0 using AArch64 depends on SCTLR_EL1.UMA, see Traps to EL1 of EL0 accesses to the PSTATE. {D, A, I, F} interrupt masks on page D1-1561. All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, except for those on memory accesses associated with fetching instructions, are guaranteed:

• Not to be visible to earlier instructions in the execution stream.
• To be visible to later instructions in the execution stream.
D1.7.2 The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the Exception level the exception is taken to. The SPSRs are described in Saved Program Status Registers (SPSRs) on page D1-1500.
D1.8 Program counter and stack pointer alignment

This section contains the following:

- PC alignment checking.
- Stack pointer alignment checking on page D1-1510.

D1.8.1 PC alignment checking

PC alignment checking generates an exception associated with instruction fetch, when an instruction fetched with a misaligned PC in AArch64 is attempted to be architecturally executed. A misaligned PC is when bits[1:0] of the PC are not 0b00.

--- Note ---

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

---

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1, unless the exception occurs in Non-secure state and HCR_EL2.TGE bit is 1, when it is taken to EL2 instead. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the Exception Syndrome Register (ESR) to 0x22, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the FAR_ELx for the Exception level that the exception is taken to.

Exception return and PC alignment on page D1-1534 gives more information on PC alignment checking associated with exception returns.

--- Note ---

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

---

// AArch64.CheckPCAlignment()
// ==========================

AArch64.CheckPCAlignment()

bits(64) pc = ThisInstrAddr();
if pc[1:0] != '00' then
  AArch64.PCAlignmentFault();

// AArch64.PCAlignmentFault()
// ==========================

// Called on unaligned program counter in AArch64 state.
AArch64.PCAlignmentFault()

bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
exception = ExceptionSyndrome(Exception_PCAlignment);
exception.vaddress = ThisInstrAddr();

if UInt(PSTATE.EL) > UInt(EL1) then
  AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
elsif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then
  AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
  AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
D1.8 Stack pointer alignment checking

A misaligned stack pointer is where bits[3:0] of the stack pointer are not 0b0000, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an exception on the attempt to execute the instruction.

--- Note ---

- As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.
- Prefetch memory abort instructions do not cause synchronous exceptions. See Prefetch memory on page C3-149.

Stack pointer alignment checking is only performed in AArch64, and can be enabled for each Exception level as follows:

- SCTLR_EL1.{SA0, SA} controls EL0 and EL1, respectively
- SCTLR_EL2.SA controls EL2
- SCTLR_EL3.SA controls EL3.

If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1 unless the HCR_EL2.TGE bit is set in the Non-secure state, when it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to 0x26, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then a stack pointer alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

```c
// CheckSPAlignment()
// ================
// Check correct stack pointer alignment for AArch64 state.

CheckSPAlignment()
bits(64) sp = SP[];
if PSTATE.EL == EL0 then
  stack_align_check = (SCTLR_EL1.SA0 != '0');
else
  stack_align_check = (SCTLR[].SA != '0');
if stack_align_check && sp != Align(sp, 16) then
  AArch64.SPAlignmentFault();
return;

// AArch64.SPAlignmentFault()
// ==========================
// Called on an unaligned stack pointer in AArch64 state.

AArch64.SPAlignmentFault()
bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
exception = ExceptionSyndrome(Exception_SPAlignment);
if UInt(PSTATE.EL) > UInt(EL1) then
  AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
elif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then
  AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
  AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```
D1.9 Reset

The ARMv8-A architecture supports the following resets:

**Cold reset**
- Resets the logic of the entire implementation, including the integrated debug functionality.
- In some contexts, this logic is described as belonging to the *Cold reset domain*.

**Warm reset**
- Resets the logic of the PE, but does not reset the integrated debug functionality.
- In some contexts, this logic is described as belonging to the *Warm reset domain*.

--- Note ---
The ARMv8-A architecture also supports an *external debug reset*. See [External debug register resets on page H8-5119](#).

The difference between a Cold reset and a Warm reset is relevant only to the debug functionality and the *RMR_ELx* register, if an *RMR_ELx* register is implemented:

- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to *RMR_ELx.RR* requests a Warm reset.

The mechanisms, other than *RMR_ELx.RR*, to assert these resets are *IMPLEMENTATION DEFINED*. It is *IMPLEMENTATION DEFINED* whether:

- It is possible to independently assert an External Debug reset and a Cold reset.
- It is possible to assert a Warm reset, as opposed to asserting a Cold reset.

--- Note ---
ARM recommends that:

- If separate Core and Debug power domains are implemented, as described in [Reset and debug on page H6-5091](#), then a Cold reset can be asserted independently of External Debug reset.
- A Warm reset can be asserted to permit debugging across a reset of the PE logic.

This means that an implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the ARMv8-A architecture. However, they can be mapped on to the resets described here.

In the description that follows, the term *reset* is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:

- The implementation must include a *Reset Management Register* (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by *RMR_ELx.AA64*.

If the highest implemented Exception level is configured to use AArch64 state, then on reset:

- The stack pointer for the highest implemented Exception level, *SP_ELx*, is selected.
- Execution starts at an *IMPLEMENTATION DEFINED* address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, *RVBAR_EL1*, *RVBAR_EL2*, or *RVBAR_EL3*, holds this address.

The remainder of this section contains the following:

- *PE state on reset to AArch64 state on page D1-1512*.
- *Code sequence to request a Warm reset as a result of RMR_ELx.RR on page D1-1513*. 
D1.9.1 PE state on reset to AArch64 state

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the PSTATE.\{D, A, I, F\} interrupt masks is set to 1.
- The Software step control bit, PSTATE.SS, is set to 0.
- The IL process state bit, PSTATE.IL, is set to 0.
- All general-purpose, and SIMD and floating-point registers are UNKNOWN.
- The ELR and SPSR for each Exception level are UNKNOWN.
- The stack pointer register for each Exception level is UNKNOWN.
- Unless explicitly defined in this subsection, each system control register at each Exception level is in an IMPLEMENTATION DEFINED state, that might be UNKNOWN.
- The TLBs and caches are in an IMPLEMENTATION DEFINED state. This means that the TLBs, the caches, or both, might require invalidation using IMPLEMENTATION DEFINED invalidation sequences before the memory management system or any cache is enabled.

Note
- The implementation might include IMPLEMENTATION DEFINED resets. If it does, each of these resets might treat the cache and TLB state differently. The ARMv8-A architecture permits this.
- Different IMPLEMENTATION DEFINED invalidation sequences might be required for different IMPLEMENTATION DEFINED resets.
- In some implementations, the IMPLEMENTATION DEFINED invalidation sequence might be a NOP.

- In the SCTLR_ELx for the highest implemented Exception level:
  - Each of the \{M, C, I\} bits is set to 0
  - The EE bit is set to an IMPLEMENTATION DEFINED value, typically defined by a configuration input.
- If an RMR is implemented, RMR_ELx.RR is set to 0. ELx in this context is the highest implemented Exception level.
- The enables for the counter event stream are set to 0. This means that the following bits are set to 0:
  - CNTKCTL_EL1.EVNTEN.
  - If the implementation includes EL2, CNTHCTL_EL2.EVNTEN.
- PMCR_EL0.E is set to 0.

Note
This means the Performance Monitors cannot assert interrupts at reset.

- OSDLR_EL1.DLK bit is set to 0.
- EDPRCR.CWRR is set to 0.
- Each of MDCCINT_EL1.\{TX, RX\} is set to 0.
- EDPRSR.SR is set to 1.
- If the implementation includes EL3, then each of MDCR_EL3.\{EPMAD, EDAD, SPME\} is set to 0.
- If the implementation includes EL2, then MDCR_EL2.HPMN is set to the value of PMCR_EL0.N.
- EDESR.SS is set to the value of EDECR.SS.
- EDESR.RC is set to the value of EDECR.RCE.
Additionally, for a Cold reset into AArch64 state:

- If an RMR is implemented, RMR_ELx.AA64 is set to 1. ELx in this context is the highest implemented Exception level.
- Each of MDCCSR_EL0.{TXfull, RXfull} is set to 0.
- The DBGPRC正常 n.ЗORENPRDREQ is set to the value of EDPRC正常.COREPURQ.
- DBGCLAIMSET_EL1[7:0] is set to 0.
- Each of EDSCR.{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} is set to 0.

### Note
MDCCSR_EL0.{RXfull, TXfull} reflect the values in EDSCR.{RXfull, TXfull}.

- Each of EDECCR.{NSE, SE} is set to 0.
- OSLSR_EL1.OSLK is set to 1.
- Each of EDPRSR.{SPMAD, SDAD} is set to 0.
- EDPRSR.SPD is set to 1.

#### D1.9.2 Code sequence to request a Warm reset as a result of RMR_ELx.RR

; in addition, interrupts and debug requests for this core should be disabled
; in the system before running this sequence to ensure the WFI suspends execution
MOV Wy, #3 ; for AArch64, #2 for AArch32; y is any register
DSB ; ensure all stores etc are complete
MSR RMR_ELx, Wy ; request the reset
ISB ; synchronise change to the RMR
Loop
  WFI ; enter a quiescent state
  B Loop

#### D1.9.3 Pseudocode description of reset

// AArch64.TakeReset()
// ================
// Reset into AArch64 state

AArch64.TakeReset(boolean cold_reset)
  assert !HighestELUsingAArch32();
  // Enter the highest implemented Exception level in AArch64 state
  PSTATE.nRW = '0';
  if HaveEL(EL3) then
    PSTATE.EL = EL3;
    SCR_EL3.NS = '0'; // Secure state
  elsif HaveEL(EL2) then
    PSTATE.EL = EL2;
  else
    PSTATE.EL = EL1;

  // Reset the system registers and other system components
  AArch64.ResetControlRegisters(cold_reset);

  // Reset all other PSTATE fields
  PSTATE.SP = '1'; // Select stack pointer
  PSTATE.<D,A,I,F> = '1111'; // All asynchronous exceptions masked
  PSTATE.SS = '0'; // Clear software step bit
  PSTATE.IL = '0'; // Clear illegal execution state bit

  // All registers, bits and fields not reset by the above pseudocode or by the BranchTo() call
// below are UNKNOWN bitstrings after reset. In particular, the return information registers
// ELR_ELx and SPSR_ELx have UNKNOWN values, so that it is impossible to return from a reset
// in an architecturally defined way.
AArch64.ResetGeneralRegisters();
AArch64.ResetSIMDFPRegisters();
AArch64.ResetSpecialRegisters();
ResetExternalDebugRegisters(cold_reset);

bits(64) rv;                      // IMPLEMENTATION DEFINED reset vector
if HaveEL(EL3) then
  rv = RVBAR_EL3;
elsif HaveEL(EL2) then
  rv = RVBAR_EL2;
else
  rv = RVBAR_EL1;

// The reset vector must be correctly aligned
assert IsZero(rv<63:PAMax()>) && IsZero(rv<1:0>);
BranchTo(rv, BranchType_UNKNOWN);

// AArch64.ResetGeneralRegisters()
// ===============================
AArch64.ResetGeneralRegisters()
  for i = 0 to 30
    X[i] = bits(64) UNKNOWN;
  return;

// AArch64.ResetSIMDFPRegisters()
// ==============================
AArch64.ResetSIMDFPRegisters()
  for i = 0 to 31
    V[i] = bits(128) UNKNOWN;
  return;

// AArch64.ResetSpecialRegisters()
// ===============================
AArch64.ResetSpecialRegisters()

// AArch64 special registers
SP_EL0 = bits(64) UNKNOWN;
SP_EL1 = bits(64) UNKNOWN;
SPSR_EL1 = bits(32) UNKNOWN;
ELR_EL1 = bits(64) UNKNOWN;
if HaveEL(EL2) then
  SP_EL2 = bits(64) UNKNOWN;
  SPSR_EL2 = bits(32) UNKNOWN;
  ELR_EL2 = bits(64) UNKNOWN;
if HaveEL(EL3) then
  SP_EL3 = bits(64) UNKNOWN;
  SPSR_EL3 = bits(32) UNKNOWN;
  ELR_EL3 = bits(64) UNKNOWN;

// AArch32 special registers that are not architecturally mapped to AArch64 registers
if HaveAArch32EL(EL1) then
  SPSR_fiq = bits(32) UNKNOWN;
  SPSR_irq = bits(32) UNKNOWN;
  SPSR_abt = bits(32) UNKNOWN;
  SPSR_und = bits(32) UNKNOWN;

// External debug special registers
DLR_EL0 = bits(64) UNKNOWN;
DSPSR_EL0 = bits(32) UNKNOWN;

return;

The ResetSystemRegisters() function resets all System registers to their reset state as defined in the register descriptions in PE state on reset to AArch64 state on page D1-1512 and Chapter D7 AArch64 System Register Descriptions.

--- Note ---

The ResetSystemRegisters() function only resets the System registers.

AAAA.Aarch.ResetSystemRegisters(boolean cold_reset);

The ResetExternalDebugRegisters() function resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 External Debug Register Descriptions.

ResetExternalDebugRegisters(boolean cold_reset);
D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See Asynchronous exception routing on page D1-1553 and Asynchronous exception masking on page D1-1553.

Note

The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

The Security state can only change on taking an exception if the exception is taken from Non-secure state to EL3.

Note

Taking an exception to EL3 from any Exception level has no effect on the value of the SCR_EL3.NS bit.

On taking an exception to AArch64 state:

• The PE state is saved in the SPSR_ELx at the Exception level the exception is taken to. See Saved Program Status Registers (SPSRs) on page D1-1500.

• The preferred return address is saved in the ELR_ELx at the Exception level the exception is taken to. See Exception Link Registers (ELRs) on page D1-1505.

• All of PSTATE.{D, A, I, F} are set to 1. See Process state, PSTATE on page D1-1506.

• If the exception is a synchronous exception or an SErr or interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the Exception level the exception is taken to. See Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1520.

• Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See Exception vectors on page D1-1517.

• The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See The stack pointer registers on page D1-1499.

The remainder of this section contains the following:

• Preferred exception return address.

• Exception vectors on page D1-1517.

• Pseudocode description of exception entry to AArch64 state on page D1-1518.

• Exception classes and the ESR_ELx syndrome registers on page D1-1520.

• Summary of register updates on faults taken to an Exception level that is using AArch64 on page D1-1532.

D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, ELR_ELx, holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

• For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.

• For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.
• For system calls, it is the address of the instruction that follows the system call instruction.

--- Note ---
• If a system call instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the system call instruction.
• A system call is generated by the execution of an SVC, HVC, or SMC instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified ELR_ELx are 0.

D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the exception vector for the exception. The exception vector exists in a vector table at the Exception level the exception is taken to.

A vector table occupies a number of consecutive word-aligned addresses in memory, starting at the vector base address.

Each Exception level has an associated Vector Base Address Register (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

• Whether the exception is one of the following:
  — Synchronous exception.
  — SError.
  — IRQ.
  — FIQ.
• Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.

Table D1-7 shows this.

<table>
<thead>
<tr>
<th>Table D1-7 Vector offsets from vector table base address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Exception taken from</strong></td>
</tr>
<tr>
<td>Current Exception level with SP_EL0.</td>
</tr>
<tr>
<td>Current Exception level with SP_ELx, x&gt;0.</td>
</tr>
<tr>
<td>Lower Exception level, where the implemented level immediately lower than the target level is using AArch64. a</td>
</tr>
<tr>
<td>Lower Exception level, where the implemented level immediately lower than the target level is using AArch32. a</td>
</tr>
</tbody>
</table>

a. For exceptions taken to EL3, if EL2 is implemented, the level immediately lower than the target level is EL2 if the exception was taken from Non-secure state, but EL1 if the exception was taken from Secure EL1 or EL0.
Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The RVBAR_ELx register contains this reset vector address, where x is the number of the highest implemented Exception level.

D1.10.3 Pseudocode description of exception entry to AArch64 state

The following pseudocode shows behavior when the PE takes an exception to an Exception level that is using AArch64.

```c
// AArch64.TakeException()
// =======================
// Take an exception to an Exception Level using AArch64.
AArch64.TakeException(bits(2) target_el, ExceptionRecord exception, bits(64) preferred_exception_return, integer vect_offset)
assert HaveEL(target_el) && !ELUsingAArch32(target_el) && UInt(target_el) >= UInt(PSTATE.EL);

// If coming from AArch32 state, the top parts of the X[] registers might be set to zero
from_32 = UsingAArch32();
if from_32 then AArch64.MaybeZeroRegisterUppers();
if UInt(target_el) > UInt(PSTATE.EL) then
    boolean lower_32;
    if target_el == EL3 then
        if !IsSecure() && HaveEL(EL2) then
            lower_32 = ELUsingAArch32(EL2);
        else
            lower_32 = ELUsingAArch32(EL1);
        else
            lower_32 = ELUsingAArch32(target_el - 1);
    vect_offset = vect_offset + (if lower_32 then 0x600 else 0x400);
elsif PSTATE.SP == '1' then
    vect_offset = vect_offset + 0x200;
spsr = GetPSRFromPSTATE();
if !(exception.type IN {Exception_IRQ, Exception_FIQ}) then
    AArch64.ReportException(exception, target_el);
PSTATE.EL = target_el;  PSTATE.nRW = '0';  PSTATE.SP = '1';
SPSR[] = spsr;
ELR[] = preferred_exception_return;
PSTATE.SS = '0';
PSTATE.<D,A,I,F> = '1111';
PSTATE.IL = '0';
if from_32 then // Coming from AArch32
    PSTATE.IT = '00000000';  PSTATE.T = '0'; // PSTATE.J is RES0
BranchTo(VBAR[] + vect_offset, BranchType_EXCEPTION);
EndOfInstruction();

// AArch64.ReportException()
// =========================
// Report syndrome information for exception taken to AArch64 state.
AArch64.ReportException(ExceptionRecord exception, bits(2) target_el)

Exception type = exception.type;
(ec,il) = AArch64.ExceptionClass(type, target_el);  iss = exception.syndrome;
// IL is not valid for Data Abort exceptions without valid instruction syndrome information
```

The RVBAR_ELx register contains the reset vector address, where x is the number of the highest implemented Exception level.
if ec IN {0x24,0x25} & iss<24> == '0' then
   il = '1';

ESR[target_el] = ec<5:0>:il:iss;

D1.10 Exception classes and the ESR_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the
exception is saved in the ESR_ELx at the Exception level the exception is taken to. The information saved is
determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes
place at the start of taking the exception. See Synchronization requirements for System registers on page D7-1902.
The following sections give more information:
• Use of the ESR_EL1, ESR_EL2, and ESR_EL3.
• EC encodings when routing exceptions to EL2 on page D1-1531.

Use of the ESR_EL1, ESR_EL2, and ESR_EL3
An ESR_ELx holds the syndrome information for an exception that is taken to AArch64 state.

Note
This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to
EL2 using AArch32.

Figure D1-2 shows the general format of the ESR_ELx registers.

Figure D1-2 Overall format of the ESR_ELx registers

The ESR_ELx fields are:

EC, bits[31:26] The Exception class field, that indicates the cause of the exception.

IL, bit[25] The Instruction length bit, for synchronous exceptions, that indicates whether a trapped
instruction was a 16-bit or a 32-bit instruction.

ISS, bits[24:0] The Instruction specific syndrome field. Architecturally, this field can be defined
independently for each defined Exception class. However, in practice, some ISS encodings
are used for more than one Exception class.

ESR_ELx, Exception Syndrome Register (ELx) on page D7-1944 describes the register in full, including:
• Listing the valid EC field values.
• Describing the ISS for each Exception class.
• Giving a full description of the use of the IL field.
Table D1-8 shows the encoding of the ESR_ELx_EC field, the Exception class field. For each EC value, the table references a subsection of the ESR_ELx register definition that describes the ISS format, with links to descriptions of possible causes of the exception, for example the configuration required to enable a trap.

### Exceptions with an unknown reason

These are the exceptions reported with an ESR_ELx.EC value of 0b000000

This encoding reports an exception with an unknown reason.
When ESR_ELx.EC returns a value of 0x00, all other fields of ESR_ELx are invalid, and defined as follows:

- IL is set to 1.
- ISS[24:0] is RES0.

An exception with an unknown reason occurs for the following reasons:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
  - Instruction encodings for instructions that are not implemented.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- An exception generated by any of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS to SP_EL0 when the value of SPSel.SP is 0.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction in Non-secure state from EL0 when the value of HCR_EL2.TGE is 1.
  - A DCPS2 instruction from EL1 or EL0 when the value of SCR_EL3.NS is 0, or when EL2 is not implemented.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution of an SRS instruction using R13_mon from Secure EL1. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MSR (Banked register) or an MRS (Banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0x07.

**Exception from a WFI or WFE instruction, from AArch32 or AArch64 state**

This is the exception syndrome with EC value 0b000001.

This reports exceptions from WFI or WFE instructions executed in either Execution state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the trapped instruction was a WFI or a WFE. ISS encoding for an exception from a WFI or WFE instruction on page D7-1950 describes the format of this syndrome.

The following sections describe configuration settings for generating these exceptions:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1560.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1578.
• Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.

**Exception from an MCR or MRC access from AArch32 state**

These are the exception syndromes with the following EC values:

- \(0b000011\), MRC or MCR access to CP15.
- \(0b000101\), MRC or MCR access to CP14.
- \(0b001000\), MRC or VMRS access to CP10.

These report exceptions from MRC, MCR, or VMRS instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of \(0b000000\).

The returned syndrome indicates whether the instruction was an MRC or an MCR, and the instruction arguments. **ISS encoding for an exception from an MCR or MRC access on page D7-1951** describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b000011\):

- Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1565.
- Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1565.
- Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1568.
- Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1570.
- Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1570.
- Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1572.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to lock down, DMA, and TCM operations on page D1-1572.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1574.
- Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1578.
- General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1580.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1583.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1584.
- Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.
- Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1588.
- Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1592.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b000101\):

- Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1563.
- Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1564.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1574, for trapped accesses to the JIDR.
- Traps to EL2 of Non-secure system register accesses to the trace registers on page D1-1579.
- Trapping System register accesses to Debug ROM registers to EL2 on page D1-1581.
- Trapping System register accesses to powerdown debug registers to EL2 on page D1-1582.
• Trapping general System register accesses to debug registers to EL2 on page D1-1582.
• Traps to EL3 of all System register accesses to the trace registers on page D1-1589.
• Trapping System register accesses to powerdown debug registers to EL3 on page D1-1591.
• Trapping general System register accesses to debug registers to EL3 on page D1-1591.

Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1574 describes configuration settings for generating exceptions that are reported using EC value 0b001000.

**Exception from an MCRR or MRRC access from AArch32 state**

These are the exception syndromes with the following EC values:

• 0b000100, MCRR or MRRC access to CP15.
• 0b001100, MRRC access to CP14.

These report exceptions from MCRR or MRRC instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0x00.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. **ISS encoding for an exception from an MCRR or MRRC access** on page D7-1954 describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

• Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1565.
• Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1565.
• Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1568.
• General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1580.
• Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1583.
• Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1584.
• Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1592.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

• Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1563.
• Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1564.
• Traps to EL2 of Non-secure system register accesses to the trace registers on page D1-1579.
• Trapping System register accesses to Debug ROM registers to EL2 on page D1-1581.
• Traps to EL3 of all System register accesses to the trace registers on page D1-1589.
• Trapping System register accesses to powerdown debug registers to EL3 on page D1-1591.

**Exception from an LDC or STC access to CP14 from AArch32 state**

This is the exception syndrome with EC value 0b000110.

This reports exceptions from LDC, or STC instructions executed in AArch32 state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. **ISS encoding for an exception from an LDC or STC access to CP14** on page D7-1956 describes the format of this syndrome.

--- **Note** ---

The only architected uses of these instructions to access CP14 are:

• An STC to write to DBGDTRRX_EL0 or DBGDTRRXint.
The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000110:

- **Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers** on page D1-1564.
- **Trapping general System register accesses to debug registers to EL2** on page D1-1582.
- **Trapping general System register accesses to debug registers to EL3** on page D1-1591.

**Exception from an access to an Advanced SIMD or floating-point register, from either Execution state, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP**

This is the exception syndrome with EC value 0b000111.

**Note**

If HCR_EL2.TGE is 1, these exceptions are reported with EC value 0b000000 instead of 0b000111. EC encodings when routing exceptions to EL2 on page D1-1531 describes this.

It reports exceptions from accesses to the Advanced SIMD and floating-point register bank, or to SIMD and floating-point System registers, when CPACR_EL1.FPEN != 0b11 or CPTR_ELx.TFP == 1.

These are taken from either Execution state.

**ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP** on page D7-1958 describes the format of the returned syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000111:

- **Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality** on page D1-1563.
- **General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers** on page D1-1579.
- **Traps to EL3 of all System register accesses to the trace registers** on page D1-1589.

**Exception from an illegal Execution State, misaligned PC, or misaligned stack pointer**

These are the exception syndromes with the following EC values:

- 0b001110, Illegal Execution State.
- 0b100010, Misaligned PC.
- 0b100110, Misaligned stack pointer.

When ESR_ELx.EC returns one of these values, the ISS field does not return any syndrome information and the ISS field is RES0.

There are no configuration settings for generating Illegal Execution State exceptions and Misaligned PC exceptions. See The Illegal Execution State exception on page D1-1536 and PC alignment checking on page D1-1509. Stack pointer alignment checking on page D1-1510 describes the configuration settings for generating Misaligned Stack Pointer exceptions.

**Exception from HVC or SVC instruction execution**

These are the exception syndromes with the following EC values:

- 0b010001, SVC instruction executed in AArch32 state.
- 0b010010, HVC instruction executed, when not disabled, in AArch32 state.
- 0b010101, SVC instruction executed in AArch64 state.
- 0b010110, HVC instruction executed, when not disabled, in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. **ISS encoding for an exception from HVC or SVC instruction execution** on page D7-1959 describes the format of this syndrome.
Note
In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

See System calls on page D1-1593.

Exception from SMC instruction execution in AArch32 state
This is the exception syndrome with EC value 0b010011.
This reports the exception from an SMC that is not disabled and is executed in AArch32 state.
ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-1960 describes the format of this syndrome.

Note
ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-1960 describes ISS[24:0] for each of the following cases:
• When an SMC instruction completes normally and generates an exception that is taken to EL3.
• When an SMC instruction is trapped to EL2 from Non-secure EL1 because HCR_EL2.TSC is set to 1.

Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1573 describes the configuration settings for trapping SMC instructions to EL2.

Exception from SMC instruction execution in AArch64 state
This is the exception syndrome with EC value 0b010111.
This reports the exception from an SMC that is not disabled and is executed in AArch64 state.
The returned syndrome indicates the immediate value given as an instruction argument. ISS encoding for an exception from SMC instruction execution in AArch64 state on page D7-1961 describes the format of this syndrome.

Note
The value of ISS[24:0] described here is used both:
• When an SMC instruction is trapped from Non-secure EL1.
• When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1573 describes the configuration settings for trapping SMC instructions to EL2.

Exception from MSR, MRS, or System instruction execution in AArch64 state
This is the exception syndrome with the EC value 0b011000.
These report exceptions from MSR, MRS, or System instructions executed in AArch64 state that result from configurable traps, enables, or disables and are not reported using the EC codes of 0b000000, 0b000001, or 0b000111.

Note
The System instruction class encoding space on page C5-244 identifies the System instructions referred to in this description.

The returned syndrome indicates whether the instruction was an MSR or an MRS, and the instruction arguments. ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state on page D7-1962 describes the format of this syndrome.
For exceptions caused by System instructions, see System on page C4-186 for the instruction arguments returned in the syndrome.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

- **In EL1 configurable controls on page D1-1559:**
  - Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-1560.
  - Traps to EL1 of EL0 accesses to the CTR_EL0 on page D1-1560.
  - Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-1561.
  - Traps to EL1 of EL0 accesses to the PSTATE.(D, A, I, F) interrupt masks on page D1-1561.
  - Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1563.
  - Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1564.
  - Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1565.
  - Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1565.

- **In EL2 configurable controls on page D1-1567:**
  - Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1568.
  - Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions on page D1-1569.
  - Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1570.
  - Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1570.
  - Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1572.
  - Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1572.
  - Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1574.
  - Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1578.
  - Traps to EL2 of Non-secure system register accesses to the trace registers on page D1-1579.
  - Trapping System register accesses to Debug ROM registers to EL2 on page D1-1581.
  - Trapping System register accesses to powerdown debug registers to EL2 on page D1-1582.
  - Trapping general System register accesses to debug registers to EL2 on page D1-1582.
  - Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1583.
  - Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1584.

- **In EL3 configurable controls on page D1-1585:**
  - Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers on page D1-1587.
  - Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1588.
  - Traps to EL3 of all System register accesses to the trace registers on page D1-1589.
  - Trapping System register accesses to powerdown debug registers to EL3 on page D1-1591.
  - Trapping general System register accesses to debug registers to EL3 on page D1-1591.
  - Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1592.
Exception from an Instruction abort

These are the exception syndromes with the following EC values:

- 0100000, for an Instruction abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0b100001, for an Instruction abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for MMU faults and synchronous external aborts, including synchronous parity or ECC errors, that are generated by instruction accesses. They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. ISS encoding for an exception from an Instruction abort on page D7-1964 describes the format of this syndrome.

Exception from a Data abort

These are the exception syndromes with the following EC values:

- 0b100100, for a Data abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0b100101, for a Data abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for the following exceptions if the exception is generated by a data access:

- MMU faults.
- Alignment faults other than those caused by stack pointer misalignment.
- Synchronous external aborts, including synchronous parity or ECC errors.

They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. ISS encoding for an exception from a Data abort on page D7-1966 describes the format of this syndrome.

Floating-point exceptions

These are the exception syndromes with the following EC values:

- 0b110100, trapped floating-point exception from AArch32.
- 0b110100, trapped floating-point exception from AArch64.

These Exception classes are supported only when the SIMD and floating-point implementation supports the trapping of floating-point exceptions. Otherwise, the 0x28 and 0x2c EC values are reserved. That is, these EC values are used to report the floating-point exceptions defined by IEEE 754, and input denormal.

The returned syndrome identifies the trapped floating-point exception or exceptions. ISS encoding for an exception from a trapped Floating-point exception on page D7-1969 describes the format of this syndrome.

In an implementation where the SIMD and floating-point implementation supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

SError interrupt

This is the exception syndrome with EC value 0b101111.

It is used to report the exception caused by an SError interrupt.
The returned syndrome is implementation specific. *ISS encoding for an SError interrupt* on page D1-1552 describes the format of this syndrome. See also *Asynchronous exception types, routing, masking and priorities* on page D1-1552.

**Breakpoint exception or Vector Catch exception**

These are the exception syndromes with the following EC values:
- \(0b110000\), Breakpoint exception taken from a lower Exception level.
- \(0b110001\), Breakpoint exception taken without a change of Exception level.
- \(0b110010\), AArch32 Vector Catch exception.

The returned syndrome provides a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Breakpoint or Vector Catch debug event* on page D7-1972 describes the format of this syndrome.

For more information about generating these exceptions, see:
- *Breakpoint exceptions* on page D2-1638.
- *Vector Catch exceptions* on page D2-1670.

**Watchpoint exception**

These are the exception syndromes with the following EC values:
- \(0b110100\), Watchpoint exception taken from a lower Exception level.
- \(0b110101\), Watchpoint exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Watchpoint debug event* on page D7-1973 describes the format of this syndrome.

For more information about generating these exceptions, see *Watchpoint exceptions* on page D2-1656.

**Software Step exception**

These are the exception syndromes with the following EC values:
- \(0b110010\), Software Step exception taken from a lower Exception level.
- \(0b110011\), Software Step exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Software Step debug event* on page D7-1972 describes the format of this syndrome.

For more information about generating these exceptions, see *Software Step exceptions* on page D2-1671.

**Software Breakpoint Instruction exception**

These are the exception syndromes with the following EC values:
- \(0b111000\), BKPT instruction executed in AArch32 state.
- \(0b111100\), BRK instruction executed in AArch64 state.

The returned syndrome provides the comment that was provided as an argument to the software breakpoint instruction. *ISS encoding for an exception from execution of a Software Breakpoint instruction* on page D7-1974 describes the format of this syndrome.

For more information about generating these exceptions, see *Software Breakpoint Instruction exceptions* on page D2-1636.

**EC encodings when routing exceptions to EL2**

When an exception is taken to EL2 because the exception routing control \(HCR_EL2\).TGE is enabled, the EC encoding that would have been used if the exception had been taken to EL1 is recorded in \(ESR_EL2\).EC instead, unless the encoding is \(0x07\).
Exceptions that use 0x07 when the HCR_EL2.TGE routing control is disabled use 0x00 when the HCR_EL2.TGE routing control is enabled.

D1.10.5 Summary of register updates on faults taken to an Exception level that is using AArch64

For all exceptions taken to an Exception level using AArch64 that are not listed in Validity of FAR_ELx, the FAR_ELx for the Exception level the exception is taken to is UNKNOWN.

For all exceptions taken to EL2 using AArch64 that are not listed in Validity of HPFAR_EL2, the HPFAR_EL2 is UNKNOWN.

Validity of FAR_ELx

The faulting virtual address is saved in FAR_ELx for the Exception level the exception is taken to if an exception is one of:

• An Instruction Abort exception.
• A Data Abort exception.
• A Misaligned PC exception.
• A Watchpoint exception.

The architecture permits that the FAR_ELx is UNKNOWN for Synchronous External Aborts other than Synchronous External Aborts on Translation Table Walks. In this case, the ISS.FnV bit returned in ESR_ELx indicates whether FAR_ELx is valid.

If an exception is taken from an Exception level using AArch32 into an Exception level using AArch64, and that exception writes the FAR_ELx at the Exception level the exception is taken to, the most significant 32 bits of the FAR_ELx are all zero, unless both:

• The faulting address was generated by a load or store that sequentially incremented from address 0xFFFFFFFF.
  Such a load or store instruction is UNPREDICTABLE.
• The implementation treats such incrementing as setting bit[32] of the virtual address.

The FAR_ELx for an Exception level is made UNKNOWN as a result of an exception return from that Exception level.

Validity of HPFAR_EL2

The faulting IPA is saved in HPFAR_EL2 if the exception is an Instruction Abort or Data Abort taken to EL2 and the fault is one of:

• A Translation or Access Flag fault on a stage 2 translation.
• A stage 2 Address Size fault.
• A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

HPFAR_EL2 is made UNKNOWN as a result of an exception return from EL2.
D1.11 Exception return

In the ARMv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
  - The initialization of a hypervisor by a Secure monitor.
  - The initialization of an operating system by a hypervisor.
  - Application entry from an operating system or hypervisor.

An exception return requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception.

In AArch64 state, an `ERET` instruction causes an exception return. On an `ERET` instruction:

- The PC is restored with the value held in the ELR_ELx.
- PSTATE is restored by using the contents of the SPSR_ELx.

The ELR_ELx and SPSR_ELx are the ELR_ELx and SPSR_ELx at the Exception level the exception is returning from.

**Note**

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the ELR_ELx are ignored.

An `ERET` instruction also:

- Sets the Event Register for the PE executing the `ERET` instruction. See *Mechanisms for entering a low-power state* on page D1-1595.
- Resets the local exclusive monitor for the PE executing the `ERET` instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a `CLREX` instruction.

**Note**

This behavior prevents self-hosted debug from software stepping through an LDREX/STREX pair. However, when self-hosted debug is using software step, it is highly probable that the exclusive monitor state would be lost anyway, for other reasons. *Stepping code that uses exclusive monitors* on page D2-1683 describes this.

It is IMPLEMENTATION DEFINED whether the resetting of the local exclusive monitor also resets the global exclusive monitor.

The `ERET` instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The ARMv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General-purpose registers.
- Special-purpose registers.
- System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.

The following sections give more information:

- *Pseudocode description of exception return* on page D1-1536.
- *Exception return and PC alignment* on page D1-1534.
- *Illegal return events from AArch64 state* on page D1-1534.
D1.11 Exception return

D1.11.1 Exception return and PC alignment

When SPSR_ELx.M[4] == 0, indicating an Exception return to AArch64 state, the value of ELR_ELx is transferred to the PC. If this value is misaligned, subsequent execution results in a Misaligned PC exception.

When SPSR_ELx.M[4] == 1, indicating an Exception return to AArch32 state, the value of ELR_ELx is transferred to the PC except that, for a legal exception return:

- If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for restoring the PC.
- If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for restoring the PC.

This means that a Misaligned PC exception cannot occur following a legal exception return from AArch64 state to AArch32 state. However, where the Exception return with SPSR_ELx.M[4] == 1 is an illegal exception return then it is IMPLEMENTATION DEFINED whether a misaligned value in ELR_ELx is aligned when it is restored to the PC.

Note

In an implementation that forces the alignment of the PC value restored from SPSR_ELx on an illegal exception return with SPSR_ELx.M[4] == 1, if SPSR_ELx.T == 1 the restored PC value might give rise to a Misaligned PC exception, because the PE remains in AArch64 state and only ELR_ELx[0] is treated as being 0 for restoring the PC.

For more information about the illegal exception return cases see Illegal return events from AArch64 state.

D1.11.2 Illegal return events from AArch64 state

In this section:

Return

In AArch64 state, refers to any of:
- Execution of an ERET instruction.
- Execution of a DRPS instruction inDebug state.
- Exit from Debug state.

Saved process state value

In AArch64 state, refers to any of:
- The value held in the SPSR_ELx for an ERET instruction.
- The value held in the SPSR_ELx for a DRPS instruction executed in Debug state.
- The value held in the DSPSR_EL0 for a Debug state exit.

Link address

In AArch64 state, refers to any of:
- The address held in ELR_ELx for an ERET instruction.
- The address held in DLR_EL0 for a Debug state exit.

Configured from reset

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling returns to a mode or state that is illegal. In AArch64 state, this can occur as the result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the Exception level being returned to is not implemented. For example a return to EL2 when EL2 is not implemented.
- A return to EL2 when EL3 is implemented and the value of the SCR_EL3.NS bit is 0.
- A return to Non-secure EL1 when EL2 is implemented and the value of the HCR_EL2.TGE bit is 1.
- A return where the value of the saved process state M[4] bit is 0, indicating a return to AArch64 state, and one of the following is true:
  - The M[3:0] bits are 0b0001.
  - The Exception level being returned to is using AArch32 state, as programmed by the SCR_EL3.RW or HCR_EL2.RW bits, or as configured from reset.
• A return where the value of the saved process state M[4] bit is 1, indicating a return to AArch32 state, and one of the following is true:
  — The M field value is not a valid AArch32 state PE mode. Table D1-4 on page D1-1503 shows the valid M[3:0] values for AArch32 state PE modes.
  — The Exception level being returned to is using AArch64 state, as programmed by the SCR_EL3.RW or HCR_EL2.RW bits, or as configured from reset.
• A Debug state exit from EL0 using AArch64 state, to EL0 using AArch32 state.

In these cases:
  • PSTATE.IL is set to 1, to indicate an illegal return.
  • PSTATE.{EL, nRW, SP} are unchanged. This means the Exception level, Execution state, and stack pointer selection do not change as a result of the return.
  • The following PSTATE bits are restored from the saved process state value:
    — The D, A, I, F exception mask bits.
  • If the illegal return is an illegal exception return, the PSTATE.SS bit is handled as normal for a return. That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See Software Step exceptions on page D2-1671.
    In all these cases the PSTATE.SS bit is handled as it would be for a normal return, as described in Entering the active-not-pending state on page D2-1674 and Exiting Debug state on page H2-5014. DRPS never sets the SS bit. This is indicated in Entering the active-not-pending state on page D2-1674.
  • If the illegal return is not a DRPS instruction executed in Debug state, the PC is restored from the link address. However, if the value of the M[4] bit of the saved process state is 1, indicating a return to AArch32 state, then:
    — It is IMPLEMENTATION DEFINED whether the PC value is aligned by setting the bottom 1 or 2 bits of its value to 0, as determined by the T bit of the saved process state. See Exception return and PC alignment on page D1-1534.
    — It is CONSTRAINED UNPREDICTABLE whether bits[63:32] of the PC are all set to zero, or are set to the value of the corresponding bits of the link address.
    The implementation determines the choice of these two options, and the choice might vary dynamically. Therefore, software must tolerate both of these options.

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution State exception. See The Illegal Execution State exception on page D1-1536.

All aspects of the illegal return, other than the effects described in this section, occur as they do for a legal return.

D1.11.3 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the same meaning as defined in Illegal return events from AArch64 state on page D1-1534.

If the value of the IL bit in the saved process state is 1, then it is copied to PSTATE by a return, meaning that PSTATE.IL is set to 1. In this case, if the return is not an illegal return, and targets AArch32 state, then the PSTATE.{IT, T} bits are either:
  • Set to 0.
  • Copied from the saved process state value.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The PSTATE.{IT, T} bits are only valid in AArch32 state, see Process state, PSTATE on page G1-3832.
When the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution State exception. See The Illegal Execution State exception.

D1.11.4 The Illegal Execution State exception

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution State exception. In AArch64 state, the PSTATE.IL bit can be set to 1 by any of:

- An illegal return, as described in Illegal return events from AArch64 state on page D1-1534.
- A legal return that sets PSTATE.IL to 1, as described in Legal returns that set PSTATE.IL to 1 on page D1-1535.

An Illegal Execution State exception sets ESR_ELx.EC for the target Exception level to the value of 0x0E.

On taking any exception to an Exception level that is using AArch64 state:

1. The value of the PSTATE.IL bit is copied into the SPSR_ELx.IL bit for the Exception level to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

Note
This means that it is not possible for software to observe the value of PSTATE.IL.

For the priority of this exception class, see Synchronous exception prioritization on page D1-1546.

D1.11.5 Pseudocode description of exception return

The ExceptionReturn() function transfers the return address to the PC and restores PSTATE to its saved value.

```
// AArch64.ExceptionReturn()
// =========================
AArch64.ExceptionReturn(bits(64) new_pc, bits(32) spsr)

// Attempts to change to an illegal state will invoke the Illegal Execution State mechanism
SetPSTATEFromPSR(spsr);
ClearExclusiveLocal(ProcessorID());
EventRegisterSet();

if spsr<4> == '1' then
    // For an attempted to change to AArch32 state, align PC[1:0] according to the target
    // instruction set state. If the exception return is illegal, it is IMPLEMENTATION DEFINED
    // whether this alignment takes place.
    align_illegal_return = boolean IMPLEMENTATION_DEFINED "align PC on illegal exception return";
if PSTATE.IL == '0' || align_illegal_return then
    if spsr<5> == '1' then // T32
        new_pc = Align(new_pc, 2);
    else // A32
        new_pc = Align(new_pc, 4);

    // If the return was illegal, the 32 most significant bits of the target PC might be zeroed
    if PSTATE.IL == '1' && ConstrainUnpredictableBool() then
        new_pc<63:32> = Zeros();

    if UsingAArch32() then
        // 32 most significant bits are ignored
        BranchTo(new_pc<31:0>, BranchType_UNKNOWN);
    else
        BranchTo(new_pc, BranchType_ERET);
```

Pseudocode description of SPSR operations on page D1-1503 describes the SetPSTATEFromPSR() function.

The IllegalExceptionReturn() function checks for an Illegal Execution State exception.
// IllegalExceptionReturn()
// ==========================

boolean IllegalExceptionReturn(bits(32) spsr)

// Check for return:
// * To unimplemented Exception level.
// * To EL2 in Secure state.
// * To EL0 using AArch64 state, with SPSR.M[0]==1.
// * To AArch64 state with SPSR.M[1]==1.
// * To AArch32 state with an illegal value of SPSR.M.
// (valid, target) = ELFromSPSR(spsr);
// if !valid then return TRUE;

// Check for return to higher Exception level
if UInt(target) > UInt(PSTATE.EL) then return TRUE;

spsr_mode_is_aarch32 = (spsr<4> == '1');

// Check for return:
// * To EL1, EL2 or EL3 with register width specified in the SPSR different from the
//   Execution state used in the Exception level being returned to, as determined by
//   the SCR_EL3.RW or HCR_EL2.RW bits, or as configured from reset.
// * To EL0 using AArch64 state when EL1 is using AArch32 state as determined by the
//   SCR_EL3.RW or HCR_EL2.RW bits or as configured from reset.
// * To AArch64 state from AArch32 state (should be caught by above)

(known, target_el_is_aarch32) = ELUsingAArch32K(target);
assert known || (target == EL0 & !ELUsingAArch32(EL1));
if known && spsr_mode_is_aarch32 != target_el_is_aarch32 then return TRUE;

// Check for illegal return from AArch32 to AArch64
if UsingAArch32() & !spsr_mode_is_aarch32 then return TRUE;

// Check for return to EL1 in Non-secure state when HCR_EL2.TGE is set
if target == EL1 & !IsSecureBelowEL3() & HCR_EL2.TGE == '1' then return TRUE;

return FALSE;
D1.12 The Exception level hierarchy

The System registers provide controls that control PE behavior through the Exception level hierarchy.

If EL3 and EL2 are implemented, System registers at EL3 and EL2 provide controls that control the Execution state of lower Exception levels.

Table D1-9 shows the principal System control registers.

<table>
<thead>
<tr>
<th>EL3</th>
<th>EL2</th>
<th>EL1</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL3</td>
<td>SCTLR_EL2</td>
<td>SCTLR_EL1</td>
<td>Controls execution for its own Exception level.</td>
</tr>
<tr>
<td>SCR_EL3</td>
<td>HCR_EL2</td>
<td>-</td>
<td>Controls execution at lower Exception levels.</td>
</tr>
<tr>
<td>-</td>
<td>HSTR_EL2</td>
<td>-</td>
<td>Used only if at least one of EL1 and EL0 is using AArch32.</td>
</tr>
</tbody>
</table>

The prioritization of exceptions generated as a result of controls in these registers is described in Synchronous exception prioritization on page D1-1546.

The following sections describe the Exception level hierarchy:
- The hierarchy of configuration and routing control.
- Control of SIMD, floating-point and trace functionality on page D1-1543.
- Control of IMPLEMENTATION DEFINED features on page D1-1544.
- Routing exceptions to EL2 on page D1-1546.

D1.12.1 The hierarchy of configuration and routing control

The following subsections give a summary of the controls available at each Exception level for controlling execution at that Exception level and all lower Exception levels:
- Controls provided at EL3.
- Controls provided at EL2 on page D1-1540.
- Controls provided at EL1 on page D1-1542.

For information on how the controls summarized in these subsections affect PE behavior, see the definitions of the control bits in the register descriptions.

Controls provided at EL3

See:
- Controls provided by the SCR_EL3.
- Controls provided by the SCTLR_EL3 on page D1-1539.
- Controls provided by the MDCR_EL3 on page D1-1539.

Controls provided by the SCR_EL3

SCR_EL3.NS Determines the Security state of execution at EL1 and EL0.

SCR_EL3.RW Determines the Execution state of the next-lower Exception level.

SCR_EL3.{EA, FIQ, IRQ}

Route:
- EA Physical SError interrupts and synchronous External Aborts to EL3.
- FIQ Physical FIQ interrupts to EL3.
- IRQ Physical IRQ interrupts to EL3.

SCR_EL3.SMD Disables the Secure Monitor Call exception.
SCR_EL3.HCE Enables the Hypervisor Call exception.
SCR_EL3.ST Enables Secure EL1 access to the Secure timer.
SCR_EL3.SIF Secure Instruction Fetch. When in Secure state, disables instruction fetches from Non-secure memory.
SCR_EL3.TWI Trap Wait-For-Interrupt.
SCR_EL3.TWE Trap Wait-For-Event.

Controls provided by the SCTLR_EL3

SCTLR_EL3.{A, SA} Enable alignment checking:
  A On data accesses from EL3.
  SA On the SP, when executing at EL3.

SCTLR_EL3.{M, C, I, WXN}
Memory system control bits:
  M Enables EL3 stage 1 address translation.
  C When set to 0, makes data accesses to Normal memory from EL3, and Normal memory accesses to the EL3 translation tables, Non-cacheable.
  I When set to 0, makes instruction accesses to Normal memory from EL3 Non-cacheable.
  WXN For accesses from EL3, enables treating all writable memory regions as XN, execute never.

SCTLR_EL3.EE Defines the endianness of data accesses from EL3, including stage 1 translation table walks at EL3.

--------------- Note -------------
Instruction fetches are always little-endian.
---------------

Controls provided by the MDCR_EL3

MDCR_EL3.{EPMAD, EDAD}
Enable external debugger accesses to:
  EPMAD Performance Monitors registers.
  EDAD Breakpoint and Watchpoint registers.

MDCR_EL3.{SPME, SDD, SPD32}
Secure debug controls:
  SPME Secure Performance Monitors enable. Enables event counting in Secure state.
  SDD Disables all debug exceptions taken from Secure state, if the debug target Exception level, EL3, is using AArch64.
  SPD32 Enables debug exceptions from Secure EL1 using AArch32.

MDCR_EL3.{TDOSA, TDA, TPM}
These are trap controls, that control traps to EL3 of EL2, EL1, and EL0 accesses to the following:
  TDOSA The OS-related debug registers.
  TDA Those debug registers not included in the MDCR_EL3.TDOSA trap.
  TPM The Performance Monitors registers.

For EL1 and EL0, these traps apply to accesses from both Security states.
**Controls provided at EL2**

EL2 is implemented only in Non-secure state, and its controls apply only to execution in Non-secure EL2, Non-secure EL1, and Non-secure EL0. See:

- **Controls provided by SCTLR_EL2.**
- **Controls provided by HCR_EL2.**
- **Controls provided by the HSTR_EL2** on page D1-1541.
- **Controls provided by the MDCR_EL2** on page D1-1542.

**Controls provided by SCTLR_EL2**

SCTLR_EL2.{A, SA} Enable alignment checking:

- **A** On data accesses from EL2.
- **SA** On the SP, when executing at EL2.

SCTLR_EL2.{M, C, I, WXN}

Memory system control bits:

- **M** Enables EL2 stage 1 address translation.
- **C** When set to 0, makes data accesses to Normal memory from EL2, and Normal memory accesses to the EL2 translation tables, Non-cacheable.
- **I** When set to 0, makes instruction accesses to Normal memory from EL2 Non-cacheable.
- **WXN** For accesses from EL2, enables treating all writable memory regions as XN, execute never.

SCTLR_EL2.EE

Defines the endianness of data accesses from EL2, including stage 1 translation table walks at EL2.

Also defines the endianness of stage 2 translation table walks at Non-secure EL1 and EL0.

--- Note

Instruction fetches are always little-endian.

**Controls provided by HCR_EL2**

HCR_EL2.RW

Determines the Execution state of the next-lower Exception level.

HCR_EL2.{AMO, IMO, FMO}

Route physical interrupts to EL2 and enable virtual interrupts:

- **AMO** Route physical SError interrupts to EL2 and enable virtual SError interrupts
- **IMO** Route physical IRQ interrupts to EL2 and enable virtual IRQ interrupts.
- **FMO** Route physical FIQ interrupts to EL2 and enable virtual FIQ interrupts.

--- Note

If a physical interrupt is routed to both EL3 and EL2, routing to EL3 takes precedence over routing to EL2.

HCR_EL2.{VSE, VI, VF}

Cause a virtual interrupt to be pending:

- **VSE** Virtual SError interrupt.
- **VI** Virtual IRQ interrupt.
- **VF** Virtual FIQ interrupt.

HCR_EL2.VM

Enable bit for Non-secure EL1&0 stage 2 address translations.
HCR_EL2.{SWIO, PTW, FB, BSU, DC, CD, ID}

Controls for memory system behavior for accesses made from Non-secure EL1 and EL0:

SWIO Set/Way Invalidate Override.
PTW Protect Table Walk.
FB Force broadcast of TLB and instruction cache maintenance instructions.
BSU Barrier Shareability Upgrade.
DC Default Cacheability control for the EL1&0 translation regime.
CD For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translation table walks to Normal memory, and stage 2 translations for data accesses to Normal memory, to be Non-cacheable.
ID For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translations for instruction accesses to Normal memory be Non-cacheable.

HCR_EL2.HCD Hypervisor Call Disable.

--- Note ---
If an implementation includes EL3, this bit is RES0.

HCR_EL2.{TRVM, TDZ, TVM, TTLB, TPU, TPC, TSW, TACR, TIDCP, TSC, TID1, TID2, TID3, TWE, TWI}

Trap operations performed at Non-secure EL1 or EL0 to EL2, as follows:
TRVM Trap Read of Virtual Memory controls.
TDZ Trap Data Cache Zero.
TVM Trap Virtual Memory controls.
TTLB Trap TLB maintenance instructions.
TPU Trap cache maintenance to the Point of Unification instructions.
TPC Trap data cache maintenance to the Point of Coherency instructions.
TSW Trap data cache maintenance by Set/Way instructions.
TACR Trap Auxiliary Control Register accesses.
TIDCP Trap Implementation-Dependent functionality.
TSC Trap Secure Monitor Call.
TID0 Trap ID Group 0 register accesses.
TID1 Trap ID Group 1 register accesses.
TID2 Trap ID Group 2 register accesses.
TID3 Trap ID Group 3 register accesses.
TWI Trap Wait-For-Interrupt.
TWE Trap Wait-For-Event.

--- Note ---
There are no AArch64 System registers in ID Group 0, therefore the TID0 trap is only relevant when Non-secure EL1 is using AArch32.

HCR_EL2.TGE Trap General Exceptions.

Controls provided by the HSTR_EL2

When EL2 is using AArch64 and at least one of Non-secure EL1 or EL0 is using AArch32, HSTR_EL2 provides the following trap of Non-secure AArch32 operation to EL2:

HSTR_EL2.Tn, for values of n in the set {0-3, 5-13, 15}

Trap accesses to System registers in the AArch32 conceptual coprocessor CP15, by the coprocessor primary register number.
Controls provided by the MDCR_EL2

MDCR_EL2.{TDRA, TDOSA, TDA}

Trap controls, that control traps to EL2 of Non-secure EL1 and EL0 System register accesses to the following:

TDRA       The Debug ROM registers.
TDOSA      The OS-related debug registers.
TDA        Those debug registers not included in either of the MDCR_EL2.TDRA or MDCR_EL2.TDOSA traps.

MDCR_EL2.TDE  Routes all debug exceptions taken from Non-secure EL1 and EL0 to EL2.

MDCR_EL2.{TPM, TPMCR}

These are trap controls, that control traps to EL2 of Non-secure EL1 and EL0 accesses to the following registers:

TPM       All Performance Monitors registers.
TPMCR     The Performance Monitors Control Registers.

MDCR_EL2.HPMN  Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 and EL0.

Controls provided at EL1

See:

• Controls provided by the SCTLR_EL1.
• Controls provided by the MDSCR_EL1 on page D1-1543.

Controls provided by the SCTLR_EL1

SCTLR_EL1.{A, SA}  Enable alignment checking:

A       On data accesses from EL1 and EL0.
SA      On the SP, when executing at EL1.

SCTLR_EL1.SA0  Enable alignment checking on the SP when executing at EL0.

SCTLR_EL1.{M, C, I, WXN}  Memory system control bits:

M       Enables EL1&0 stage 1 address translation.
C       When set to 0, makes data accesses to Normal memory from EL0 and EL1, and Normal memory accesses to the EL1&0 stage 1 translation tables, Non-cacheable.
I       When set to 0, makes instruction accesses to Normal memory from EL1 and EL0 Non-cacheable.
WXN     For accesses from EL1 and EL0, enables treating all writable memory regions as XN, execute never.

SCTLR_EL1.EE  Defines the endianness of data accesses from EL1, including stage 1 translation table walks at EL1 and EL0.

_____ Note  ____________

Instruction fetches are always little-endian.

SCTLR_EL1.E0E  EL0 Endianness. Defines the endianness used for explicit data accesses made from EL0.
SCTLR_EL1.{UCI, UCT, DZE, nTWI, nTWE}

Trap enables:
- **UCI**: Unprivileged Cache maintenance Instruction enable.
- **UCT**: Unprivileged Cache Type access enable.
- **DZE**: Data cache Zero Enable.
- **nTWI**: Not Trap Wait-For-Interrupt.
- **nTWE**: Not Trap Wait-For-Event.

SCTLR_EL1.UMA

Unprivileged Mask Access.

SCTLR_EL1.{SED, ITD, CP15BEN}

These bits control AArch32 functionality that is deprecated, or OPTIONAL and deprecated:
- **SED**: Disables use of the SETEND instruction.
- **ITD**: Disables use of the IT instruction.
- **CP15BEN**: Enables use of the CP15 DMB, DSB, and ISB barrier operations.

**Controls provided by the MDSCR_EL1**

MDSCR_EL1.{MDE, SS}

Enable controls for the debug exceptions:
- **MDE**: Enables Breakpoint exceptions, Watchpoint exceptions, and Vector Catch exceptions.
- **SS**: Enables Software Step exceptions.

There is no enable control for Software Breakpoint Instruction exceptions. Software Breakpoint Instruction exceptions are always enabled.

MDSCR_EL1.KDE

Enables debug exceptions from EL_D when EL_D is using AArch64.

MDSCR_EL1.TDCC

Enables a trap to EL1 of EL0 accesses to the Debug Communications Channel registers.

**D1.12.2 Control of SIMD, floating-point and trace functionality**

In addition to the controls described in *The hierarchy of configuration and routing control on page D1-1538*, the following registers provide a hierarchy of control of access to SIMD and floating-point functionality, and to trace functionality that is accessible using the System registers:

**CPTR_EL3**

Traps operation at lower Exception levels to EL3, if the operation is not trapped to EL2 by CPTR_EL2 and is not trapped to EL1 by CPACR_EL1.

**CPTR_EL2**

Traps operation in Non-secure EL1 or EL0 to EL2, if the operation is not trapped to EL1 by CPACR_EL1. CPTR_EL2.{TTA, TFP} also trap operation in EL2.

The trap bits in the CPTR_EL3 and CPTR_EL2 are as follows:
- **TCPAC**: Traps accesses to the registers that control access to SIMD, floating-point, and trace functionality.
- **TTA**: Traps any System register access to trace functionality, unless that access is otherwise trapped to a lower Exception level.
- **TFP**: Traps any execution of an instruction that uses the SIMD and floating-point register bank, unless that access is otherwise trapped to a lower Exception level.

**CPACR_EL1**

Traps operation from EL1 or EL0 to EL1. Traps set in the CPACR_EL1 take precedence over any traps set in the CPTR_EL2 or CPTR_EL3. The trap fields are as follows:
- **TTA**: Traps to EL1 any System register access from EL0 or EL1 to trace functionality.
- **FPEN**: Traps to EL1 execution of instructions that uses the SIMD and floating-point register bank.
D1.12.3 Control of IMPLEMENTATION DEFINED features

The hierarchy of configuration and routing control on page D1-1538 and Control of SIMD, floating-point and trace functionality on page D1-1543 describe the controls of the trapping of architecturally-defined functionality. However, the architecture also defines registers that can be used to provide IMPLEMENTATION DEFINED traps of IMPLEMENTATION DEFINED functionality to the different Exception levels. Table D1-10 shows these control registers, for AArch64 state controls.

Table D1-10 Control of traps of IMPLEMENTATION DEFINED functionality

D1.13 Synchronous exception types, routing and priorities

Synchronous exceptions are:

- **UNDEFINED** exceptions generated by:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instruction bit patterns that have not been allocated.

- Illegal Execution State exceptions. These are caused by attempts to execute an instruction when the value of PSTATE.IL is 1, see *Illegal return events from AArch64 state* on page D1-1534.

- Exceptions caused by the use of a misaligned Stack Pointer.

- Exceptions caused by attempting to execute an instruction with a misaligned PC.

- Exceptions caused by the exception-generating instructions SVC, HVC, or SMC.

- Traps on attempts to execute instructions that the System Control registers define as instructions that are trapped to a higher Exception level. See *Configurable instruction enables and disables, and trap controls* on page D1-1558.

- Instruction Aborts generated by the memory address translation system, that are associated with attempts to execute instructions from areas of memory that generate Faults.

- Data Aborts generated by the memory address translation system, that are associated with attempts to read or write memory that generate Faults.

- Data Aborts caused by a misaligned address.

- All of the debug exceptions:
  - Software Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.

- In an implementation that supports the trapping of floating-point exceptions, exceptions caused by trapped IEEE floating-point exceptions, see *Floating-point exception traps* on page D1-1549.

- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The ARMv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See *External aborts* on page D3-1711.

This remainder of this section contains the following:

- *Routing exceptions to EL2* on page D1-1546.
- *Synchronous exception prioritization* on page D1-1546.
- *Effect of Data Aborts* on page D1-1549.
- *Floating-point exception traps* on page D1-1549.
D1.13 Synchronous exception types, routing and priorities

D1.13.1 Routing exceptions to EL2

When HCR_EL2.TGE is 1, any exception taken from Non-secure EL0 that would be taken to Non-secure EL1 is, instead, routed to EL2. This means that an application can execute at Non-secure EL0 without using any functionality at Non-secure EL1.

Note

Implementations typically use the following Exception level and software hierarchy in Non-secure state:

<table>
<thead>
<tr>
<th>EL2</th>
<th>Hypervisor.</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL1</td>
<td>Operating system.</td>
</tr>
<tr>
<td>EL0</td>
<td>Application.</td>
</tr>
</tbody>
</table>

In such an implementation, setting HCR_EL2.TGE to 1 means that an application can run at Non-secure EL0 under the direct control of a hypervisor executing at EL2, with no operating system involvement.

D1.13.2 Synchronous exception prioritization

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. For exceptions taken to an exception level that is using AArch64, these are prioritized as follows, where 1 is the highest priority:

2. Misaligned PC exceptions. See PC alignment checking on page D1-1509.
3. Instruction Abort exceptions. See Exception from an Instruction abort on page D1-1530 and Prioritization of synchronous aborts from a single stage of address translation on page D4-1822.
4. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
   - Breakpoint exceptions on page D2-1638.
   - Vector Catch exceptions on page D2-1670.

Vector Catch exceptions are only taken from AArch32 state.

Note

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3845. This means that it is outside the scope of the description of this section.

5. Illegal Execution State exceptions. See Illegal return events from AArch64 state on page D1-1534.

6. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
   - HSTR_EL2.Tn.
   - HCR_EL2.TIDCP.

For exceptions taken from AArch64 state:

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are HSTR.Tn and HCR.TIDCP.

7. Undefined Instruction exceptions that occur as a result of one or more of the following:
   - An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
   - An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
   - Debug state execution of an instruction encoding that is unallocated in Debug state.
• Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
• Execution of an **HVC** instruction, when **HVC** instructions are disabled by SCR_EL3.HCE or HCR_EL2.HCD.
• Execution of an **MSR** or **MRS** instruction to **SP_EL0** when the value of **SPSel** is 0.
• Execution of a **HLT** instruction when **HLT** instructions are disabled by EDSCR.HDE.

In Debug state, execution of:

— A **DCPS1** instruction in Non-secure EL0 when HCR_EL2.TGE is 1.
— A **DCPS2** instruction in EL1 or EL0 when SCR_EL3.NS is 0 or when EL2 is not implemented.
— A **DCPS3** instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
— When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.

• When executing in AArch32 state, execution of an instruction that is **UNDEFINED** as a result of any of:
  — Being in an IT block when SCTLR_EL1.ITD is 1.
  — Executing a **SETEND** instruction executed SCTLR_EL1.SED.
  — Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when SCTLR_EL1.CP15BEN is 0.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are SCTLR.{ITD, SED, CP15BEN}, with additional controls HSCTLR.{ITD, SED, CP15BEN}.

See Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-1562

• When executing in AArch32 state, execution of an instruction that is **UNDEFINED** because at least one of FPCR.{Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See Floating-point exception traps on page G1-3917.

8. Exceptions taken to EL1, or taken to EL2 because the value of HCR_EL2.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-7.

Note

When EL2 is using AArch32, the equivalent control for routing exceptions to EL2 is HCR.TGE.

9. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
   • HSTR_EL2.Tn.
   • HCR_EL2.TIDCP.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are HSTR.Tn and HCR.TIDCP.

10. Exceptions taken to EL2 because of configuration settings in the CPTR_EL2.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are in the HCPTR.

11. Exceptions taken to EL2 because of one of the following configuration settings:
   • Any setting in HCR_EL2, other than the TIDCP bit.
   • Any setting in CNTHCTL_EL2.
   • Any setting in MDCR_EL2.
Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are:

- Any setting in HCR, other than the TIDCP bit.
- Any setting in CNTHCTL or HDCR.

12. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1-11.
13. Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR_EL3.SMD is 1.
14. Exceptions caused by the execution of an Exception generating instruction:
   - For exceptions taken from AArch64 state, Branches, Exception generating, and System instructions on page C3-136 defines these instructions.
   - When executing in AArch32 state, the exception-generating instructions are SVC, HVC, SMC, and BKPT.
15. Exceptions taken to EL3 because of configuration settings in the CPTR_EL3.
16. Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.
17. Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in the MDCR_EL3.
18. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 1-17.
19. Trapped floating-point exceptions, if supported. See Floating-point exception traps on page D1-1549.
20. Stack Pointer Alignment faults. See Stack pointer alignment checking on page D1-1510.
21. Data Abort exceptions other than a Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item 23. See Exception from a Data abort on page D1-1530 and Prioritization of synchronous aborts from a single stage of address translation on page D4-1822. It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 23.
22. Watchpoint exceptions. See Watchpoint exceptions on page D2-1656.
23. Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk, see External aborts on page D3-1711. It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 21.

For items 21-23, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

Note

Exceptions generated by a translation table walk are reported and prioritized as either an Instruction Abort exception, priority 3 in this list, or a Data Abort exception, priority 21 in this list. See also Prioritization of synchronous aborts from a single stage of address translation on page D4-1822.
D1.13.3 Effect of Data Aborts

If an instruction that stores to memory generates a Data Abort, the value of each memory location that instruction stores to is either:

- Unchanged, if one of the following applies:
  - An MMU fault is generated.
  - A Watchpoint exception is generated.
  - An external abort is generated, if that external abort is taken synchronously.

**Note**

If an external abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the external abort. However, in general, ARM recommends that such memory locations are not updated.

- UNKNOWN for any location for which no exception and no debug event is generated.

For external aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

**Note**

For the definition of a single-copy atomic access, see Single-copy atomicity on page B2-81.

For Data Aborts from load or store instructions executed in AArch64 state, if the:

**Data Abort is taken synchronously**

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

**Data Abort is taken asynchronously, using the SError interrupt**

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.

**Note**

Data Aborts taken asynchronously are known as Asynchronous Aborts in AArch32 state.

D1.13.4 Floating-point exception traps

Execution of a floating-point instruction can generate an exceptional condition, called a floating-point exception.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.
Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.
- For an implementation that does not provide this capability, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

Note

The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, unless they are taken from Non-secure state when HCR_EL2.TGE is 1, when they are taken to EL2 instead.
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

The exception is reported in the ELR_ELx for the Exception level to which it is taken.

In an implementation that includes synchronous exception generation for floating-point exceptions:

- Synchronous exception generation applies to floating-point exceptions generated by scalar SIMD and floating-point instructions executed in AArch64 state.
- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception flags in the event of such an exception.
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported, however the element that is reported is identified in the ESR_ELx.

The FPTrappedException() and FPProcessException() pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

```c
// AArch64.FPTrappedException()
// -----------------------------------------
AArch64.FPTrappedException(boolean is_ase, integer element, bits(8) accumulated_exceptions)
exception = ExceptionSyndrome(Exception_FPTrappedException);
exception.syndrome<23> = '1';                                // TFV
if is_ase then exception.syndrome<10:8> = element<2:0>;      // VECITR
exception.syndrome<7,4:0> = accumulated_exceptions<7,4:0>;   // IDF,IXF,UFF,OFF,DZF,IOF
route_to_el2 = HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1';
bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
if UInt(PSTATE.EL) > UInt(EL1) then
    AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
elsif route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
```

AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

// FPProcessException()
// ====================
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

FPProcessException(FPExc exception, FPCRType fpcr)
// Determine the cumulative exception bit number
    case exception of
        when FPExc_InvalidOp     cumul = 0;
        when FPExc_DivideByZero  cumul = 1;
        when FPExc_Overflow      cumul = 2;
        when FPExc_Underflow     cumul = 3;
        when FPExc_Inexact       cumul = 4;
        when FPExc_InputDenorm   cumul = 7;
        enable = cumul + 8;
    if fpcr<enable> == '1' then
        // Trapping of the exception enabled.
        // It is IMPLEMENTATION DEFINED whether the enable bit may be set at all, and
        // if so then how exceptions may be accumulated before calling FPTrapException()
        IMPLEMENTATION_DEFINED "floating-point trap handling";
    elsif UsingAArch32() then
        // Set the cumulative exception bit
        FPSCR<cumul> = '1';
    else
        // Set the cumulative exception bit
        FPSR<cumul> = '1';
    return;

D1.14 Asynchronous exception types, routing, masking and priorities

In the ARMv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as **interrupts**.

There are two types of interrupts:

- **Physical interrupts** are signals sent to the PE from outside the PE. They are:
  - SError. System Error.
  - IRQ.
  - FIQ.

- **Virtual interrupts** are interrupts that a Hypervisor executing in EL2 can enable. A virtual interrupt is taken from Non-secure EL0 or Non-secure EL1 to a Guest OS running in Non-secure EL1. Virtual interrupts have names that correspond to the physical interrupts:
  - vSError.
  - vIRQ.
  - vFIQ.

--- **Note** ---

The AArch64 SError interrupt replaces the AArch32 asynchronous abort. The new name better describes the nature of the exception, and means that it is categorized as a unique exception class, with EC encoding 0x2F.

---

An external abort generated by the memory system might be taken asynchronously using the SError interrupt. The effect of a failed memory access is described in **Effect of Data Aborts on page D1-1549**.

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in **Asynchronous exception routing on page D1-1553**.

When an interrupt occurs:

- On taking an SError or a vSError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated with the encoding for an SError interrupt. See **Exception classes and the ESR_ELx syndrome registers on page D1-1520**.
- On taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:

- **Asynchronous exception routing on page D1-1553**.
- **Asynchronous exception masking on page D1-1553**.
- **Virtual interrupts on page D1-1555**.
- **Prioritization and recognition of asynchronous exceptions on page D1-1556**.
- **Taking an interrupt or other exception during a multiple-register load or store on page D1-1557**.
D1.14.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64.

In the tables, C indicates that the interrupt is not taken, regardless of the Process state interrupt mask.

Table D1-11 Routing when both EL3 and EL2 are implemented

<table>
<thead>
<tr>

a. If HCR_EL2.TGE is 1, these bits are treated as being 1 other than for a direct read.

D1.14.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.
In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

- **S Error**: PSTATE.A
- **IRQ**: PSTATE.I
- **FIQ**: PSTATE.F

When the target Exception level is higher than the current Exception level:
- If the target Exception level is EL2 or EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the PSTATE.{A, I, F} bits.

**Note**
- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The PSTATE.{A, I, F} bits can mask both physical interrupts and virtual interrupts.
- The ARMv8-A architecture does not support Non-maskable FIQ (NMFI) operations. This means that it does not provide a configuration option to override the masking of FIQs by PSTATE.F.

On taking any exception to an Exception level using AArch64, all of PSTATE.{A, I, F} are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:
- For implementations that include both EL2 and EL3, see Table D1-14.
- For implementations that include EL3 but not EL2, see Table D1-15 on page D1-1555.
- For implementations that include EL2 but not EL3, see Table D1-16 on page D1-1555.

For the masking of virtual interrupts, see Virtual interrupts on page D1-1555.

In the tables:
- **A**: When the interrupt is asserted it is taken regardless of the value of the Process state interrupt mask.
- **B**: When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.
- **C**: When the interrupt is asserted it is not taken, regardless of the value of the Process state interrupt mask.

---

<sup>a</sup> If EL2 is using AArch64, these are the **HCR_EL2**.{AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the **HCR**.{AMO, IMO, FMO} control bits. If **HCR_EL2.TGE** or **HCR.TGE** is 1, these bits are treated as being 1 other than a direct read.
D1.14.3 Virtual interrupts

Setting an HCR_EL2.{FMO, IMO, AMO} routing control bit to 1 enables the corresponding virtual interrupt, unless HCR_EL2.TGE is 1. When the value of HCR_EL2.TGE is 1 all virtual interrupts are disabled.

Virtual interrupts can only be taken from Non-secure EL0 to EL1 or from Non-secure EL1 to EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, to 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

Note

For a usage model for virtual interrupts, see Virtual interrupt usage model on page D1-1497.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR_EL1.

Each virtual interrupt type can be masked when execution is in Non-secure EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, PSTATE.{A, I, F}.

When execution is in Secure state, or in EL3 or EL2, all types of virtual interrupt are always masked.
Table D1-17 summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

<table>
<thead>
<tr>
<th>Virtual interrupt type</th>
<th>Enable control</th>
<th>Cause a virtual interrupt to be pending</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSError</td>
<td>HCR_EL2.AMO</td>
<td>HCR_EL2.VSE</td>
</tr>
<tr>
<td>vIRQ</td>
<td>HCR_EL2.IMO</td>
<td>HCR_EL2.VI</td>
</tr>
<tr>
<td>vFIQ</td>
<td>HCR_EL2.FMO</td>
<td>HCR_EL2.VF</td>
</tr>
</tbody>
</table>

On taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in the HCR_EL2 retains its state.

On taking a vSError interrupt, HCR_EL2.VSE is cleared to 0.

--- Note ---

This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing in EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

As with physical interrupts:

- Taking a vSError interrupt to an Exception level using AArch64 updates ESR_EL1 with the dedicated encoding for an SError interrupt. For the encoding, see Exception classes and the ESR_ELx syndrome registers on page D1-1520.
- Taking a vIRQ or a vFIQ interrupt to an Exception level using AArch64 does not update the ESR_EL1.

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

- When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.
- When the interrupt is asserted it is not taken, regardless of the value of the Process state interrupt mask.

<table>

</tbody>
</table>

a. If EL2 is using AArch64, these are the HCR_EL2.{TGE, AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the HCR{TGE, AMO, IMO, FMO} control bits.

**D1.14.4 Prioritization and recognition of asynchronous exceptions**

The ARMv8-A architecture does not define when interrupts are taken. The prioritization of interrupts, including virtual interrupts, is IMPLEMENTATION DEFINED.
Any interrupts that are pending prior to one of the following context synchronizing events, are taken before the first instruction after the context synchronizing event, provided that the interrupt is not masked:

- An ISB instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

--- **Note** ---

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.
- The ISR_EL1 register indicates whether an interrupt is pending.
- Interrupts are masked when the PE is in Debug state, so this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

### D1.14.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

If an interrupt, or another exception, is taken from AArch64 during the execution of an instruction that performs a sequence of memory accesses, rather than a single single-copy atomic access, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, can contain an **UNKNOWN** value. Registers used in the generation of the address are restored to their initial value.
- For a store, any data location being stored to by the instruction can contain an **UNKNOWN** value.
- For either a load or a store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

--- **Note** ---

- This interrupt behavior is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory access caused by a single load or store instruction.
- In both Execution states, synchronous data abort exceptions can be taken during the execution of an instruction that performs a sequence of memory accesses.
- Software must avoid using multiple-register load and store instructions for accesses to Device memory, particularly to Device memory with the non-Gathering attribute, because an exception taken during the load or store can result in repeated accesses.
D1.15 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch64 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control.

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Exception level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

Trap controls

Control whether one or more particular instructions, whenever executed at a particular Exception level, are trapped.

A trapped instruction generates a Trap exception.

For trap controls provided by:

- **EL1**  
  Trap exceptions are taken to EL1, unless routed from Non-secure EL0 to EL2 because HCR_EL2.TGE is 1.

- **EL2**  
  Trap exceptions are taken to EL2.

- **EL3**  
  Trap exceptions are taken to EL3.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if both of the following apply:

- The instruction generating the exception does not also generate a higher priority exception. Synchronous exception prioritization on page D1-1546 defines the prioritization of different exceptions on the same instruction.

- The instruction is not UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE instructions can generate exceptions as a result of these controls, but the architecture does not require them to do so.

Exceptions generated as a result of these controls are synchronous exceptions.

For:

- Undefined Instruction exceptions, the PE reports EC value 0x00 in the ESR_ELx. This is the value for an exception for an unknown or uncategorized reason.

- Trap exceptions, the PE reports the applicable EC value and associated syndrome in the ESR_ELx. Table D1-8 on page D1-1521 includes the EC values that are used for Trap exceptions.

**Note**

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, SCTLR_EL1.DZE is a trap control even though DZE means DC ZVA Enable.

- Software executing at EL2 can also use a routing control, HCR_EL2.TGE, to route exceptions from EL0 to EL2. See Routing exceptions to EL2 on page D1-1546. HCR_EL2.TGE is not a trap control.

- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

This section is organized as follows:

- Register access instructions on page D1-1559.
- EL1 configurable controls on page D1-1559.
- EL2 configurable controls on page D1-1567.
- EL3 configurable controls on page D1-1585.
D1.15.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

D1.15.2 EL1 configurable controls

These controls are in _EL1 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL1.M[4] indicates which Execution state the exception was taken from.

Table D1-19 shows the _EL1 System registers that contain these controls.

Table D1-19 _EL1 registers that contain instruction enables and disables, and trap controls

Traps to EL1 of EL0 execution of cache maintenance instructions

SCTLR_EL1.UCI traps EL0 execution of cache maintenance instructions to EL1:

1. EL0 execution of cache maintenance instructions is not trapped to EL1.
2. Any attempt to execute a cache maintenance instruction at EL0 is trapped to EL1.

Table D1-21 shows the instructions that are trapped to EL1, and how the exceptions are reported in ESR_EL1.

**Table D1-21 Instructions trapped to EL1 when SCTLR_EL1.UCI is 0**

<table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the CTR_EL0

SCTLR_EL1.UCT traps EL0 accesses to the CTR_EL0 to EL1:

1. EL0 accesses to the CTR_EL0 are not trapped to EL1.
2. EL0 accesses to the CTR_EL0 are trapped to EL1.

Table D1-22 shows how the exceptions are reported in ESR_EL1.

**Table D1-22 Register accesses trapped to EL1 when SCTLR_EL1.UCT is 0**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 execution of WFE and WFI instructions

SCTLR_EL1.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to EL1:

**SCTLR_EL1.nTWE**

1. EL0 execution of WFE instructions is not trapped to EL1.
2. Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

**SCTLR_EL1.nTWI**

1. EL0 execution of WFI instructions is not trapped to EL1.
2. Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.
In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

Note
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

Traps to EL1 of EL0 execution of DC ZVA instructions
SCTLR_EL1.DZE traps EL0 execution of DC ZVA instructions to EL1:

1  EL0 execution of DC ZVA instructions is not trapped to EL1.

0  Any attempt to execute a DC ZVA instruction at EL0 is trapped to EL1. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not supported.

Table D1-24 shows how the exceptions are reported in ESR_EL1.

Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks
SCTLR_EL1.UMA traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1:

1  EL0 execution of MSR or MRS instructions that access the DAIF is not trapped to EL1.

0  Any attempt at EL0 to execute an MSR or an MRS instruction that accesses the DAIF is trapped to EL1.
Table D1-25 shows how the exceptions are reported in ESR_EL1.

<table>

</tbody>
</table>

a. SETEND instruction disable. SETEND instructions are disabled when this is 1.
b. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Undefined Instruction exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.
c. IT instruction disable. Some uses of IT instructions are disabled when this is 1.
d. CP15 barrier operation instruction enable. Accesses to the CP15 DMB, DSB, and ISB barrier operations are disabled when this is 0.

Instructions disabled when SCTLR_EL1.ITD is 1

When SCTLR_EL1.ITD is 1, any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED.

- All encodings of the IT instruction with hw1[3:0]=1000.
- All encodings of the subsequent instruction with the following values for hw1:

  0b11xxxxxxxxxxxxxx
  - All 32-bit instructions.
  - All of the following 16-bit instructions:
    - B
    - UDF
    - SVC
    - LDM
    - STM
  0b1011xxxxxxxxxxxxxx
  - All instructions in Miscellaneous 16-bit instructions on page F3-2536.
  0b10100xxxxxxxxxxx
  - ADD Rd, PC, #imm
Traps to EL1 of EL0 and EL1 System register accesses to the trace registers

CPACR_EL1.TTA traps EL0 and EL1 System register accesses to the trace registers to EL1.

1 EL0 and EL1 System register accesses to the trace registers are trapped to EL1.

0 EL0 and EL1 System register accesses to the trace registers are not trapped to EL1.

--- Note ---

1. The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefinied Instruction exception is higher priority than a CPACR_EL1.TTA Trap exception.

2. The ARMv8-A architecture does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page D1-1559.

Table D1-27 shows the registers for which accesses are trapped to EL1 when CPACR_EL1.TTA is 1, and how the exceptions are reported in ESR_EL1.

<table>
<thead>
<tr>

</tbody>
</table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.
Traps to EL1 of EL0 accesses to the Generic Timer registers

CNTKCTL_EL1.EL0PTEN, CNTKCTL_EL1.EL0VTEN, CNTKCTL_EL1.EL0PCTEN, CNTKCTL_EL1.EL0VCTEN trap EL0 accesses to the Generic Timer registers to EL1, as follows:

• CNTKCTL_EL1.EL0PTEN traps EL0 accesses to the physical timer registers.
• CNTKCTL_EL1.EL0VTEN traps EL0 accesses to the virtual timer registers.
• CNTKCTL_EL1.EL0PCTEN traps EL0 accesses to the frequency register and physical counter register.
• CNTKCTL_EL1.EL0VCTEN traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

1                   EL0 accesses are not trapped to EL1.
0                   EL0 accesses are trapped to EL1.

Accesses to the frequency register, CNTFRQ_EL0 or CNTFRQ, are only trapped if CNTKCTL_EL1.EL0PCTEN and CNTKCTL_EL1.EL0VCTEN are both 0.

Table D1-30 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL1.

Table D1-30 Register accesses trapped from EL0 to EL1 by CNTKCTL_EL1 trap controls

|           | EL0VCTEN | CNTFRQ, CNTVCT | a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to Performance Monitors registers

PMUSERENR_EL0. {ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to EL1. For each of these controls:

1                   EL0 accesses are not trapped to EL1.
0                   EL0 accesses are trapped to EL1.

For those Performance Monitors registers that more than one PMUSERENR_EL0. {ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

Table D1-31 on page D1-1566 shows:

• The registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.
• How the exceptions are reported in ESR_EL1.

Also see the following for more general information about traps to EL2:

- **Register access instructions** on page D1-1559.
- For traps from an Exception level using AArch32:
  - **Instructions that fail their condition code check** on page G1-3928.
  - **Instructions that are UNPREDICTABLE** on page G1-3929.

### Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers

**HCR_EL2.{TRVM, TVM}** trap Non-secure EL1 accesses to the virtual memory control registers to EL2:

**HCR_EL2.TRVM, for read accesses:***

- 1: Non-secure EL1 reads of the virtual memory control registers are trapped to EL2.
- 0: Non-secure EL1 reads of the virtual memory control registers are not trapped to EL2.

**HCR_EL2.TVM, for write access:***

- 1: Non-secure EL1 writes to the virtual memory control registers are trapped to EL2.
- 0: Non-secure writes to the virtual memory control registers are not trapped to EL2.

Table D1-34 on page D1-1569 shows the registers for which:

- Reads are trapped to EL2 when **HCR_EL2.TRVM** is 1.
- Writes are trapped to EL2 when **HCR_EL2.TVM** is 1.
Table D1-34 also shows how the exceptions are reported in ESR_EL2.

### Table D1-34 Register read and write accesses trapped when HCR_EL2.{TRVM, TVM} are 1

</tr>
</tbody>
</table>

---

**Note**

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

---

**Disabling Non-secure state execution of HVC instructions**

HCR_EL2.HCD disables Non-secure state execution of HVC instructions:

1. HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

0. HVC instruction execution is enabled at EL2 and Non-secure EL1.

---

**Note**

HVC instructions are always UNDEFINED at EL0.

---

HCR_EL2.HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0.

Table D1-35 shows how the exceptions are reported in ESR_ELx.

### Table D1-35 Instruction disabled when HCR_EL2.HCD is 1

---

**Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions**

HCR_EL2.TDZ traps Non-secure EL0 and EL1 execution of DC ZVA instructions to EL2:

1. Any attempt to execute a DC ZVA instruction at Non-secure EL0 or EL1 is trapped to EL2. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not supported.

0. Non-secure EL0 and EL1 execution of DC ZVA instructions is not trapped to EL2.
Table D1-36 shows how the exceptions are reported in ESR_EL2.

Table D1-36 Instruction trapped to EL1 when HCR_EL2.TDZ is 0

Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

HCR_EL2.TTLB traps Non-secure EL1 execution of TLB maintenance instructions to EL2:

1  Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to EL2.
0  Non-secure EL1 execution of TLBI instructions is not trapped to EL2.

Table D1-37 shows the instructions that are trapped, and how the exceptions are reported in ESR_EL2.

Table D1-37 Instructions trapped to EL2 when HCR_EL2.TTLB is 1

<table>
<thead>
<tr>

<td>TLBIALLLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAIS, TLBIMVALIS, TLBIMVAALIS, TLBIMVAAIS, TLBIMVAIS, ITLBIALL, ITLBIMVA, ITLBISID, DTLBIALL, DTLBIMVA, DTLBIASID, DTLBIAALL, DTLBIMVA, DTLBIASID, DTLBIMVA, DTLBIMVAAL.</td>
<td>Trapped MSR or MR CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>

Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see:

- *TLB maintenance instructions* on page D4-1830, for the AArch64 state instructions.
- *The scope of TLB maintenance instructions* on page G4-4142, for the AArch32 state instructions.

Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions

HCR_EL2.{TSW, TPC, TPU} trap cache maintenance instructions to EL2. When one of these controls is 1, any attempt to execute a corresponding cache maintenance instruction at Non-secure EL1, or at Non-secure EL0 if permitted by SCTLR_EL1.UCI, is trapped to EL2.

Table D1-38 Controls for trapping cache maintenance instructions to EL2

<tr>
<td>AArch32 state</td>
<td>ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>

**Note**

**IC IALLUIS and IC IALLU** are always **UNDEFINED** at EL0 using AArch64.

**ICIMVAU, ICIALLU, ICIALLUIS, and DCCMVAU** are always **UNDEFINED** at EL0 using AArch32.

For more information about these instructions, see:

- **Cache maintenance instructions, and data cache zero** on page C5-250 for the AArch64 instructions.
- **Cache maintenance instructions, functional group** on page G4-4239 for the AArch32 instructions.
Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register

HCR_EL2.TACR traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2:

1
Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to EL2.

0
Non-secure EL1 accesses to the Auxiliary Control Registers are not trapped to EL2.

Table D1-42 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-42 Register accesses trapped to EL2 when HCR_EL2.TACR is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>ACTLR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32</td>
<td>ACTLR and, if implemented, the ACTLR2.</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>

---

**Note**

- The ACTLR_EL1, ACTLR, and ACTLR2 are not accessible at EL0.
- The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

---

**Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations**

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of system control registers for control of these features.

HCR_EL2.TIDCP traps the execution of system register access instructions that access these registers, as follows:

1
At Non-secure EL1, any attempt to execute a system control register access instruction with a reserved register encoding is trapped to EL2.

At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute system control register access instructions with reserved register encodings are:

- Trapped to EL2.
- UNDEFINED, and the PE takes an Undefined Instruction exception to EL1.

0
Non-secure EL0 and EL1 system register access instructions with reserved register encodings are not trapped to EL2.
Table D1-43 shows the register encodings for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-43 Encodings trapped to EL2 when HCR_EL2.TIDCP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register encodings</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>Any access to any of the encodings described in <em>Reserved control space for IMPLEMENTATION DEFINED functionality</em> on page C5-263.</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32</td>
<td>An access to any of the following encodings:</td>
<td></td>
</tr>
<tr>
<td>state</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>

<td></td>
</tr>
<tr>
<td></td>
<td>See <em>VMSAv8-32 CP15 c10 register summary</em> on page G4-4216.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>See <em>VMSAv8-32 CP15 c11 register summary</em> on page G4-4216.</td>
<td></td>
</tr>
</tbody>
</table>

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

---

**Note**

- ARM expects the trapping of Non-secure EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. ARM strongly recommends that unless the hypervisor must virtualize EL0 operation, a Non-secure EL0 access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure EL1.

- The trapping of accesses to these registers from Non-secure EL1 is higher priority than Undefined Instruction exceptions.

### Traps to EL2 of Non-secure EL1 execution of SMC instructions

HCR_EL2.TSC traps Non-secure EL1 execution of SMC instructions to EL2:

1. Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of SCR_EL3.SMD.

2. Non-secure EL1 execution of SMC instructions is not trapped to EL2.

If EL3 is not implemented, HCR_EL2.TSC is RES0.

Table D1-44 shows how the exceptions are reported in ESR_EL2:

### Table D1-44 SMC Instruction trapped to EL2 when HCR_EL2.TSC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>SMC</td>
<td>Trapped SMC instruction execution in AArch64 state, using EC value 0x17</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>SMC on page F7-3040</td>
<td>Trapped SMC instruction execution in AArch32 state, using EC value 0x13</td>
</tr>
</tbody>
</table>

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

For more information about SMC instructions, see *SMC on page C6-689.*
Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.
- HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers

Other than the MIDR_EL1, MPIDR_EL1, and PMCR_EL0.N, the ID registers are divided into groups, with a trap control in the HCR_EL2 for each group.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Register group</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR_EL2.TID0</td>
<td>ID group 0, Primary device identification registers on page D1-1575</td>
</tr>
<tr>
<td>HCR_EL2.TID1</td>
<td>ID group 1, Implementation identification registers on page D1-1575</td>
</tr>
<tr>
<td>HCR_EL2.TID2</td>
<td>ID group 2, Cache identification registers on page D1-1576</td>
</tr>
<tr>
<td>HCR_EL2.TID3</td>
<td>ID group 3, Detailed feature identification registers on page D1-1577</td>
</tr>
</tbody>
</table>

These controls trap register accesses to EL2, as follows:

**HCR_EL2.TID0**
When 1, any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to EL2.

**HCR_EL2.TID1**
When 1, any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to EL2.

**HCR_EL2.TID2**
When 1, any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the CSSELR or CSSELR_EL1, is trapped to EL2.

**HCR_EL2.TID3**
When 1, any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to EL2.

For the MIDR_EL1 and MPIDR_EL1, and for PMCR_EL0.N, the architecture provides read/write aliases. The original register becomes accessible only from EL2 or Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

<table>
<thead>
<tr>
<th>Register</th>
<th>Original</th>
<th>Alias, EL2 using AArch64</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main ID</td>
<td>MIDR_EL1</td>
<td>VPIDR_EL2</td>
</tr>
<tr>
<td>Multiprocessor Affinity</td>
<td>MPIDR_EL1</td>
<td>VMPIDR_EL2</td>
</tr>
<tr>
<td>Performance Monitors Control Register</td>
<td>PMCR_EL0.N</td>
<td>MDCR_EL2.HPMN</td>
</tr>
</tbody>
</table>

Reads of the MIDR_EL1, MPIDR_EL1 or PMCR_EL0.N from EL2 or Secure state are unchanged by the implementation of EL2, and access the physical registers.
Note

- If the optional Performance Monitors Extension is not implemented, MDCR_EL2.HPMN is RES0 and PMCR_EL0 is reserved.
- MDCR_EL2.HPMN also affects whether a Performance Monitors counter can be accessed from Non-secure EL0 or EL1. See the register description of MDCR_EL2 for more information.
- PMCR_EL0 contains other fields that identify the implementation. For more information about trapping accesses to the PMCR_EL0, see Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1584.

ID group 0, Primary device identification registers

In:
- AArch64 state, there are no ID group 0 registers.
- AArch32 state, these registers identify some top-level implementation choices.

Table D1-47 shows the registers that are in ID group 0 for traps to EL2, and how the exceptions are reported in ESR_EL2.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>FPSID</td>
<td>Trapped CP10 access, using EC value 0x08</td>
</tr>
<tr>
<td></td>
<td>JIDR</td>
<td>Trapped CP14 access, using EC value 0x05</td>
</tr>
</tbody>
</table>

Note

The FPSID is not accessible from EL0 using AArch32.

When the FPSID is accessible, a T32 or A32 VMSR FPSID, <&t> instruction is permitted but is ignored. The execution of this VMSR instruction execution is not trapped by the ID group 0 trap.

ID group 1, Implementation identification registers

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table D1-48 shows the registers that are in ID group 1 for traps to EL2, and how the exceptions are reported in ESR_EL2.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 1 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>REVIDR_EL1, AIDR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>TCMTR, TLBTR, REVIDR, AIDR</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>
**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table D1-49 shows the registers that are in ID group 2 for traps to EL2, and how the exceptions are reported in ESR_EL2.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 2 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>CTR, CCSIDR, CLIDR, CSSELR</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>
**ID group 3, Detailed feature identification registers**

These registers provide detailed information about the features of the implementation.

--- **Note** ---

- In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See The CPUID identification scheme on page G4-4233.

Table D1-50 shows the registers that are in ID group 3 for traps to EL2, and how the exceptions are reported in ESR_EL2.

**Table D1-50 ID group 3 registers**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 3 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td><strong>ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1.</strong> <strong>ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1</strong>, and, if it contains a non-zero value, <strong>ID_MMFR4_EL1</strong>. <strong>ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1.</strong> <strong>MVFR0_EL1, MVFR1_EL1, MVFR2_EL1.</strong> <strong>ID_AA64PFR0_EL1, ID_AA64PFR1_EL1.</strong> <strong>ID_AA64DFR0_EL1, ID_AA64DFR1_EL1.</strong> <strong>ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1.</strong> <strong>ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1.</strong> <strong>ID_AA64AFR0_EL1, ID_AA64AFR1_EL1.</strong></td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td><strong>MVFR0, MVFR1, MVFR2.</strong></td>
<td>Trapped CP10 access, using EC value 0x8</td>
</tr>
</tbody>
</table>

Any MCR access to any of the following CP15 encodings:

- CRn == c0, opc1 == 0, CRn == {c3-c7}, opc2 == {0, 1}.
- CRn == c0, opc1 == 0, CRn == c3, opc2 == 2.
- CRn == c0, opc1 == 0, CRn == c5, opc2 == {4, 5}.

It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MCR accesses to CP15 encodings in the following range that are not already mentioned in this table:

- CRn == c0, opc1 == 0, CRn == {c2-c7}, opc2 == {0-7}.
Traps to EL2 of Non-secure EL0 and EL1 execution of \texttt{WFE} and \texttt{WFI} instructions

\texttt{HCR\_EL2\{TWE, TWI\}} trap Non-secure EL0 and EL1 execution of \texttt{WFE} and \texttt{WFI} instructions to EL2:

\texttt{HCR\_EL2.TWE}:
- \texttt{1} Any attempt to execute a \texttt{WFE} instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
- \texttt{0} Non-secure EL0 or EL1 execution of \texttt{WFE} instructions is not trapped to EL2.

\texttt{HCR\_EL2.TWI}:
- \texttt{1} Any attempt to execute a \texttt{WFI} instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
- \texttt{0} Non-secure EL0 or EL1 execution of \texttt{WFI} instructions is not trapped to EL2.

Table D1-51 shows how the exceptions are reported in ESR\_EL2.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{HCR_EL2.TWE}</td>
<td>Both Execution states</td>
<td>\texttt{WFE} or \texttt{WFI}</td>
<td>Trapped \texttt{WFI} or \texttt{WFE} instruction, using EC value 0x01</td>
</tr>
<tr>
<td>\texttt{HCR_EL2.TWI}</td>
<td></td>
<td>\texttt{WFI}</td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional \texttt{WFE} or \texttt{WFI} instruction is only trapped if the instruction passes its condition code check.

\textbf{Note}

Since a \texttt{WFE} or \texttt{WFI} can complete at any time, even without a Wakeup event, the traps on \texttt{WFE} or \texttt{WFI} are not guaranteed to be taken, even if the \texttt{WFE} or \texttt{WFI} is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
- \textit{Wait for Event mechanism and Send event} on page D1-1595.
- \textit{Wait For Interrupt} on page D1-1598.

Trapping to EL2 of Non-secure EL1 accesses to the CPACR\_EL1 or CPACR

\texttt{CPTR\_EL2.TCPAC} traps Non-secure EL1 accesses to the CPACR\_EL1 or CPACR to EL2:
- \texttt{1} Non-secure EL1 accesses to the CPACR\_EL1 or CPACR are trapped to EL2.
- \texttt{0} Non-secure EL1 accesses to the CPACR\_EL1 or CPACR are not trapped to EL2.

Table D1-52 shows how the exceptions are reported in ESR\_EL2.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CPACR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>CPACR</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>
Note

• The CPACR_EL1 or CPACR is not accessible at EL0.

• In ARMv7 and earlier versions of the ARM architecture, one function of the CPACR is as an ID register that identifies what coprocessor functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism.

General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers

CPTR_EL2.TFP traps Non-secure accesses to SIMD and floating-point registers to EL2:

1  Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2.

0  Non-secure execution of instructions that access the SIMD or floating-point registers is not trapped to EL2.

Table D1-53 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

Table D1-53 Register accesses trapped to EL2 when CPTR_EL2.TFP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See The SIMD and floating-point registers, V0-V31 on page D1-1500.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point system registers on page G1-3916.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07</td>
</tr>
</tbody>
</table>

a. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

Traps to EL2 of Non-secure system register accesses to the trace registers

CPTR_EL2.TTA traps System register accesses to the trace registers to EL2. These traps are from Non-secure state, so are from all of:

• EL2.
• Non-secure EL0 and EL1.

When CPTR_EL2.TTA is:

1  Non-secure system register accesses to the trace registers are trapped to EL2.

0  Non-secure system register accesses to the trace registers are not trapped to EL2.

Note

• The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than a CPTR_EL2.TTA Trap exception.

• EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page D1-1559.
Table D1-54 shows the registers for which accesses are trapped to EL2 when CPTR_EL2.TTA is 1, and how the exceptions are reported in ESR_EL2.

### Table D1-54 Register accesses trapped to EL2 when CPTR_EL2.TTA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>All implemented trace registers</td>

<td>• MCRR or MRRC instructions, trapped MCRR or MRRC CP15 access, using EC value 0x0C.</td>
</tr>
</tbody>
</table>

General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only

HSTR_EL2.T0-T3, T5-T13, T15} trap accesses to the CP15 System registers, by the accessed primary CP15 register number, {c0-c3, c5-c13, c15}. These traps are from AArch32 state only. They are from both:
- Non-secure EL1 using AArch32.
- Non-secure EL0 using AArch32.

When a HSTR_EL2.Tx trap control is:
- 1: Any AArch32 state Non-secure EL1 or EL0 access to the corresponding register is trapped to EL2.
- 0: AArch32 state Non-secure EL1 or EL0 accesses to the corresponding register are not trapped to EL2.

Table D1-55 shows the accesses that are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-55 Accesses trapped to EL2 when a HSTR_EL2.Tx trap is enabled

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>

<td>MCR and MRC instructions, where Crn in the instruction corresponds to the trapped primary CP15 register</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>MCRR and MRRC instructions, where Crn in the instruction corresponds to the trapped primary CP15 register</td>
<td>Trapped MCRR or MRRC CP15 access, using EC value 0x04</td>
</tr>
</tbody>
</table>

---

**Note**

HSTR_EL2[4, 14] is reserved, RES0, although the Generic Timer control registers are implemented in CP15 c14. EL2 does not provide a trap on accesses to the Generic Timer CP15 registers.

---

**CP15 register with IMPLEMENTATION DEFINED access permission from EL0**

For a trapped primary CP15 register, if it is IMPLEMENTATION DEFINED whether, when the corresponding trap control is 0, an access from Non-secure User mode is UNDEFINED, then when the corresponding trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure EL0 using AArch32 generates:
- A Trap exception taken to EL2.
- An Undefined Instruction exception taken to Non-secure EL1.

If the instruction generates an Undefined Instruction exception taken to Non-secure EL1, and Non-secure EL1 is using AArch64, the exception is reported in ESR_EL1 as an exception for an unknown reason, using EC value 0x00.
--- Note ---

ARM expects that trapping of Non-secure EL0 accesses to EL2 will be unusual, and used only when the hypervisor must virtualize EL0 operation. ARM recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the Non-secure EL0 access, that access generates an Undefined Instruction exception that is taken to Non-secure EL1.

--- Note ---

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers

MDCR_EL2.\{TDRA, TDOSA, TDA\} trap Non-secure System register accesses to the debug registers to EL2, as follows:

- MDCR_EL2.\{TDRA, TDA\} trap Non-secure EL0 and EL1 accesses.
- MDCR_EL2.TDOSA traps Non-secure EL1 accesses.

--- Note ---

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See Register access instructions on page D1-1559.

Table D1-56 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in ESR_EL2.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCR_EL2.TDRA</td>
<td>Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers</td>
</tr>
<tr>
<td>MDCR_EL2.TDOSA</td>
<td>Trapping System register accesses to powerdown debug registers to EL2 on page D1-1582</td>
</tr>
<tr>
<td>MDCR_EL2.TDA</td>
<td>Trapping general System register accesses to debug registers to EL2 on page D1-1582</td>
</tr>
</tbody>
</table>

Trapping System register accesses to Debug ROM registers to EL2

MDCR_EL2.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to EL2:

1 Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2.

0 Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are not trapped to EL2.

This trap applies to Non-secure EL0 only if it is using AArch32.

Table D1-57 shows the register accesses that are trapped, and how the exceptions are reported in ESR_EL2.

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>MDRAR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>DBGDRAR, DBGDSAR</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCR or MRC instructions, trapped MCR or MRC CP14 access, using EC value 0x05.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCRR or MRRC instructions, trapped MCRR or MRRC CP14 access, using EC value 0x0C.</td>
</tr>
</tbody>
</table>
If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDRA is 1 other than for the purpose of a direct read.

**Trapping System register accesses to powerdown debug registers to EL2**

MDCR_EL2.TDOSA traps Non-secure EL1 System register accesses to the powerdown debug registers to EL2:

| 1 | Non-secure EL1 System register accesses to the powerdown debug registers are trapped to EL2. |
| 0 | Non-secure EL1 System register accesses to the powerdown debug registers are not trapped to EL2. |

Table D1-58 shows the register accesses that are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-58 Register accesses trapped to EL2 when MDCR_EL2.TDOSA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1.</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.</td>
</tr>
<tr>
<td></td>
<td>Any IMPLEMENTATION DEFINED integration registers.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by MDCR_EL2.TDOSA.</td>
<td></td>
</tr>
<tr>
<td>AArch32 state</td>
<td>DBGOSLAR, DBGOSLSR, DBGOSDLR, DBGPRCR.</td>
<td>Trapped MCR or MRC CP14 access, using EC value 0x05.</td>
</tr>
<tr>
<td></td>
<td>Any IMPLEMENTATION DEFINED integration registers.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA.</td>
<td></td>
</tr>
</tbody>
</table>

---

**Note**

These registers are not accessible at EL0.

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDOSA is 1 other than for the purpose of a direct read.

**Trapping general System register accesses to debug registers to EL2**

MDCR_EL2.TDA traps Non-secure EL0 and EL1 System register accesses to those debug System registers that are not mentioned in either of the following:

- *Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers on page D1-1581.*
- *Trapping System register accesses to powerdown debug registers to EL2.*

This means that MDCR_EL2.TDA traps Non-secure EL0 and EL1 System register accesses to all debug System registers to EL2, except the following:

- Any access from:
  - AArch64 state to the MDRAR_EL1.
  - AArch32 state to the DBGDRAR or DBGDSAR.

MDCR_EL2.TDRA traps these accesses.

- Any access from:
  - AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
  - AArch32 state to the DBGOSLAR, DBGOSLSR, DBGOSDLR or DBGPRCR.

MDCR_EL2.TDOSA traps these accesses.

MDCR_EL2.TDA does not trap accesses to the DBGDTRRX_EL0, DBGDTRTX_EL0, or DBGDTR_EL0 when the PE is in Debug state.

When MDCR_EL2.TDA is:

| 1 | Non-secure EL0 or EL1 System register accesses to any of the registers shown in Table D1-59 on page D1-1583 are trapped to EL2. |
Non-secure EL0 or EL1 System register accesses to the registers shown in Table D1-59 are not trapped to EL2. Table D1-59 shows how the exceptions are reported in ESR_EL2.

### Table D1-59 Accesses trapped to EL2 when MDCR_EL2.TDA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>Accesses to the MDCCSR_EL0, MDCCINT_EL1, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, OSDTRRX_EL1, MDSCR_EL1, OSDTRTX_EL1, OSECCR_EL1, DBGVR&lt;n&gt;_EL1, DBGBCR&lt;n&gt;_EL1, DBGWVR&lt;n&gt;_EL1, DBGWCR&lt;n&gt;_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, and DBGAUTHSTATUS_EL1.</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>Accesses to the DBGIDDR, DBGDCINT, DBGDCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGSCRext, DBGDTRRXext, DBGDTRTXext, DBGVR&lt;n&gt;, DBGBCR&lt;n&gt;, DBGXVR&lt;n&gt;, DBGWVR&lt;n&gt;, DBGWCR&lt;n&gt;, DBGWVR&lt;n&gt;, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGDESECCR.</td>
<td>For accesses using MCR or MRC instructions, trapped MCR or MRC CP14 access, using EC value 0x05</td>
</tr>
</tbody>
</table>

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDA is 1 other than for the purpose of a direct read.

### Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers

CNTHTCTL_EL2.{EL1PCEN, EL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to EL2, as follows:

- **CNTHTCTL_EL2.EL1PCEN** traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- **CNTHTCTL_EL2.EL1PCTEN** traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

- **1** Non-secure EL0 and EL1 accesses are not trapped to EL2.
- **0** Non-secure EL0 and EL1 accesses are trapped to EL2.

Table D1-60 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-60 Register accesses trapped to EL2 by CNTHTCTL_EL2 trap controls

^a. **T** indicates a trap control, **E** indicates an instruction enable, and **D** indicates an instruction disable. For the definitions of these terms, see the list that begins with *Instruction enables and instruction disables* on page D1-1558.

Also see the following for more general information about traps to EL3:

- Register access instructions on page D1-1559.
- Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.
Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

• Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR.
• Any attempt at Secure EL1 to execute any of the following:
  — ATS12NSOxx instructions.
  — SRS instructions that use the R13_mon banked register.
  — MRS or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers.

In addition, if EL1 is using AArch32:

• Secure EL1 write accesses to the CNTFRQ register are UNDEFINED. They are not trapped to EL3.
• Any attempt at Secure EL1 to change the mode to Monitor mode, by using a CPS or an MSR instruction, or by performing an exception return, is treated as an illegal change of the CPSR.M field. See Illegal changes to PSTATE.M on page G1-3836.

Table D1-65 shows the accesses that are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-65 Accesses trapped to EL3 from Secure EL1 using AArch32

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Trapped instructions, or trapped accesses</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure EL1 using AArch32</td>
<td>Reads and writes to any of the SCR, NSACR, MVBAR or SDCR</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>ATS12NSOxx instructions</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td></td>
<td>SRS instructions that use the R13_mon banked register</td>
<td></td>
</tr>
<tr>
<td></td>
<td>MRS or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers</td>
<td></td>
</tr>
</tbody>
</table>

Note

• Reads of the NSACR from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value 0x00000C00. See Restricted access System registers on page G4-4195.

• These operations are not available at EL0.

Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions

SCR_EL3.{TWE, TWI} trap EL2, EL1, and EL0 execution of WFE and WFI instructions to EL3:

**SCR_EL3.TWE**

1  Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.

0  EL2, EL1, and EL0 execution of WFE instructions is not trapped to EL3.

**SCR_EL3.TWI**

1  Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.

0  EL2, EL1, and EL0 execution of WFI instructions is not trapped.

For EL0 and EL1, these traps apply to WFE and WFI execution in both Security states.
Table D1-66 shows how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.TWE</td>
<td>Both Execution</td>
<td>WFE</td>
<td>Trapped WFI or WFE instruction, using EC value 0x01</td>
</tr>
<tr>
<td>SCR_EL3.TWI</td>
<td>states</td>
<td>WFI</td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

**Note**

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait for Event mechanism and Send event* on page D1-1595.
- *Wait For Interrupt* on page D1-1598.

**Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers**

SCR_EL3.ST traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3:

- **1** Secure EL1 accesses to the Counter-timer Physical Secure timer registers are not trapped to EL3.
- **0** Secure EL1 accesses to the Counter-timer Physical Secure timer registers are trapped to EL3.

**Note**

Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3.

Table D1-67 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Traps from</th>

</tr>
<tr>
<td></td>
<td>CTNPS_CVVAL_EL1</td>
<td></td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Note**

These registers are not accessible at EL0.

**Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions**

SCR_EL3.HCE enables HVC instruction execution at EL1 and above:

- **1** HVC instruction execution is enabled at EL1 and above.
HVC instructions are UNDEFINED at EL1, EL2, and EL3. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

For EL1, this enable control applies to HVC instructions in Non-secure state only.

If EL2 is not implemented, this bit is RES0.

--- Note ---
HVC instructions are always UNDEFINED at EL0.

Table D1-68 shows how the exceptions are reported in ESR_ELx.

### Table D1-68 Instruction disabled when SCR_EL3.HCE is 0

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled Instruction</th>
<th>Syndrome reporting in ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>HVC</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>AArch32 state</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Disabling EL3, EL2, and EL1 execution of SMC instructions

SCR_EL3.SMD disables SMC instruction execution at EL1 and above:

1 SMC instructions are UNDEFINED at EL1 and above. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

0 SMC instruction execution is enabled at EL1 and above.

For EL1, this disable control applies to SMC instructions in both Security states.

--- Note ---
SMC instructions are always UNDEFINED at EL0.

Table D1-69 shows how the exceptions are reported in ESR_ELx.

### Table D1-69 Exceptions generated when SCR_EL3.SMD is 1

<table>
<thead>
<tr>
<th>Taken from</th>

<td>SMC</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>AArch32 state</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

--- Note ---
If HCR_EL2.TSC or HCR.TSC traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL3.TCPAC traps all of the following to EL3:

- EL2 accesses to the CPTR_EL2 or HCPTR.
- EL2 and EL1 accesses to the CPACR_EL1 or CPACR.
When CPTR_EL3.TCPAC is:

1
   EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3.

0
   EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-70 shows how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>

<td>HCPTR CPACR</td>
<td>Trapped MCR or MRC CP15 access, using EC value 0x03</td>
</tr>
</tbody>
</table>

Traps to EL3 of all System register accesses to the trace registers

CPTR_EL3.TTA traps System register accesses to the trace registers, from all Exception levels, to EL3:

1
   All System register accesses to the trace registers are trapped to EL3.

0
   System register accesses to the trace registers are not trapped to EL3.

Note

• The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than a CPTR_EL3.TTA Trap exception.

• EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page D1-1559.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-71 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>

   • MCR or MRC instructions, trapped MCR or MRC CP14 access, using EC value 0x05.
   • MCRR or MRRC instructions, trapped MCRR or MRRC CP14 access, using EC value 0x0C. |
Traps to EL3 of all accesses to the SIMD and floating-point registers

CPTR_EL3.TFP traps all accesses to SIMD and floating-point registers, from all Exception levels, to EL3:

1     Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3

0     Execution of instructions that access the SIMD or floating-point registers is not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-72 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-72 Register accesses trapped to EL3 when CPTR_EL3.TFP is 1

<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1 FPEN or CPTR_ELx.TFP, using EC value 0x07</td>
</tr>
</tbody>
</table>

Note

- FPEXC32_EL2 is not accessible from EL0 using AArch64.
- FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers

MDCR_EL3.\{TDOSA, TDA\} trap EL2, EL1, and EL0 System register accesses to the debug registers to EL3, from both Security states.

Note

EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See Register access instructions on page D1-1559. Table D1-73 shows the subsections that list the accesses trapped.

Table D1-73 Traps of EL2, EL1, and EL0 accesses to debug registers

<table>
<thead>
<tr>

#### Note

These registers are not accessible at EL0.

---

**Trapping general System register accesses to debug registers to EL3**

MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to the debug System registers that are not mentioned in **Trapping System register accesses to powerdown debug registers to EL3**.

This means that MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to all debug System registers, except the following:

- Accesses from AArch64 state to the OSLAR_EL1, OLSLR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
- Accesses from AArch32 state to the DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR.

When MDCR_EL3.TDA is:

1  EL2, EL1, and EL0 System register accesses to any of the registers shown in Table D1-75 on page D1-1592 are trapped to EL3.
0  EL2, EL1, and EL0 System register accesses to the registers shown in Table D1-75 on page D1-1592 are not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

MDCR_EL3.TDA does not trap accesses to the DBGDTRRX_EL0, DBGDTRTX_EL0, or DBGDTR_EL0 when the PE is in Debug state.
Table D1-75 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

| &nbsp; • MRRR or MRRR instructions, trapped MRRR or MRRR CP15 access, using EC value 0x04. |
D1.16 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.

- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default.
  
  The HVC instruction is UNDEFINED:
  - At EL0.
  - At EL1 in Secure state.

  Note
  Software executing at EL0 cannot directly generate a Hypervisor Call.

- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3.
  
  The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:

- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then it generates a synchronous exception that is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:

- Disabling Non-secure state execution of HVC instructions on page D1-1569.
- Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-1587.

EL2 can trap use of the SMC instruction, see Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1573.

EL3 can disable Secure Monitor Call exceptions, see Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-1588.

D1.16.1 Pseudocode description of system calls

The pseudocode for the CallSupervisor() function is as follows:

```cpp
// AArch64.CallSupervisor()
// ========================
// Calls the Supervisor

AArch64.CallSupervisor(bits(16) immediate)
```

```
if UsingAArch32() then AArch32.ITAdvance();
SSAdvance();
```

```
route_to_el2 = HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && HCR_EL2.TGE == '1';
```

```
bits(64) preferred_exception_return = NextInstrAddr();
vect_offset = 0x0;
```

```
exception = ExceptionSyndrome(Exception_SupervisorCall);
```

```
exception.syndrome<15:0> = immediate;
```

```
if UInt(PSTATE.EL) > UInt(EL1) then
AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
```
elsif route_to_el2 then
    AArch64.TakException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakException(EL1, exception, preferred_exception_return, vect_offset);

The pseudocode for the CallHypervisor() function is as follows:

// AArch64.CallHypervisor()
// ========================
// Performs a HVC call
AArch64.CallHypervisor(bits(16) immediate)
assert HaveEL(EL2);
if UsingAArch32() then AArch32.ITAdvance();
SSAdvance();
bits(64) preferred_exception_return = NextInstrAddr();
vect_offset = 0x0;
exception = ExceptionSyndrome(Exception_HypervisorCall);
exception.syndrome<15:0> = immediate;
if PSTATE.EL == EL3 then
    AArch64.TakException(EL3, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakException(EL2, exception, preferred_exception_return, vect_offset);

The pseudocode for the CallSecureMonitor() function is as follows:

// AArch64.CallSecureMonitor()
// ===========================
AArch64.CallSecureMonitor(bits(16) immediate)
assert HaveEL(EL3) && !ELUsingAArch32(EL3);
if UsingAArch32() then AArch32.ITAdvance();
SSAdvance();
bits(64) preferred_exception_return = NextInstrAddr();
vect_offset = 0x0;
exception = ExceptionSyndrome(Exception_MonitorCall);
exception.syndrome<15:0> = immediate;
AArch64.TakException(EL3, exception, preferred_exception_return, vect_offset);
D1.17 Mechanisms for entering a low-power state

The ARM architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- Wait for Event mechanism and Send event.
- Wait For Interrupt on page D1-1598.

D1.17.1 Wait for Event mechanism and Send event

A PE can use the Wait for Event (WFE) mechanism to enter a low-power state, depending on the value of an Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, WFE, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a WFE wake-up event.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFE instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection The Event Register on page D1-1596.
- The Wait For Event instruction, WFE. See subsection The Wait For Event instruction on page D1-1596.
- WFE wake-up events. See subsection WFE wake-up events in AArch64 state on page D1-1597.
- The Send Event instructions, SEV and SEVL that can cause WFE wake-up events. See subsection The Send Event instructions on page D1-1597.

Note

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, ARM recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

Example D1-2 describes how a spinlock implementation might use the WFE mechanism to save energy.

Example D1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in Synchronization and semaphores on page B2-107.
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.
A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multiprocessor system the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a `WFE` instruction to request entry to a low-power state, at the time when the exclusive monitor is set holding the address of the location holding the lock.
- When a PE releases a lock, the write to the lock location causes the exclusive monitor of any PE monitoring the lock location to be cleared. This clearing of the exclusive monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

---

### The Event Register

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a `WFE` instruction.

The reset value of the Event Register is `UNKNOWN`.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, `SEV`, executed by any PE in the system.
- A Send Event Local instruction, `SEVL`, executed by the PE.
- The clearing of the global monitor for the PE.
- An exception return.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

---

**Note**

Software cannot read or write the value of the Event Register directly.

---

### The Wait For Event instruction

The action of the Wait For Event instruction, `WFE`, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.

- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or a until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

The `WFE` instruction is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1560.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1578.](#)
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1586.](#)
Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.

**WFE wake-up events in AArch64 state**

The following are *WFE wake-up events*:

- The execution of an *SEV* instruction on any PE in the multiprocessor system.
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by *EDSCR.INTdis* and:
  - Is marked as A in the tables in *Asynchronous exception masking* on page D1-1553, regardless of the value of the corresponding *PSTATE.{A, I, F}* mask bit.
  - Is marked as B in the tables in *Asynchronous exception masking* on page D1-1553, if the value of the corresponding *PSTATE.{A, I, F}* mask bit is 0.
- In Non-secure EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by *EDSCR.INTdis* and is marked as B in Table D1-18 on page D1-1556 in *Virtual interrupts* on page D1-1555, if the value of the corresponding *PSTATE.{A, I, F}* mask bit is 0.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see *Halting allowed and halting prohibited* on page H2-4977.
  - See also *External Debug Request debug event* on page H2-4977.
  - An event sent by the timer event stream for the PE. See *Event streams* on page D6-1895.
  - An event caused by the clearing of the global monitor for the PE.
  - An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

The disabling of interrupts, and WFE wake-up events, by *EDSCR.INTdis* is possible only when external debug is enabled.

**The Send Event instructions**

The Send Event instructions are:

- **SEV, Send Event** This causes an event to be signaled to all PEs in the multiprocessor system.
- **SEVL, Send Event Local** This must set the local Event Register.

It might signal an event to other PEs by some IMPLEMENTATION DEFINED mechanism, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the *SEV* instruction. Therefore, ARM recommends that software includes a *DSB* instruction before any *SEV* instruction.
Note
A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See Data Synchronization Barrier (DSB) on page B2-88.

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.
The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.
The SEV and SEVL instructions are available at all Exception levels.

Pseudocode description of the Wait For Event mechanism
This section defines pseudocode functions that describe the behavior of the Wait For Event mechanism.
The ClearEventRegister() pseudocode procedure clears the Event Register of the current PE.

ClearEventRegister();

The EventRegistered() pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear:

boolean EventRegistered();

The WaitForEvent() pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a ClearEventRegister() to occur.

WaitForEvent();

The SendEvent() pseudocode procedure sets the Event Register of every PE in the multiprocessor system.

SendEvent();

The EventRegisterSet() pseudocode procedure sets the event register for this PE.

EventRegisterSet();

D1.17.2 Wait For Interrupt
Software can use the Wait for Interrupt (WFI) instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a WFI wake-up event, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

Note
Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.
The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.
Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1560.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1578.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1586.
WFI wake-up events

The following are WFI wake-up events:

- Any physical SEError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as A as B in the tables in Asynchronous exception masking on page D1-1553, regardless of the value of the corresponding PSTATE.\{A, I, F\} mask bit.

- In Non-secure EL1 or EL0, any virtual SEError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as B in Table D1-18 on page D1-1556 in Virtual interrupts on page D1-1555, regardless of the value of the corresponding PSTATE.\{A, I, F\} mask bit.

- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-4977.
  See also External Debug Request debug event on page H3-5034.

- An event sent by some IMPLEMENTATION DEFINED mechanism.

Note

- WFI wake-up events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE.\{A, I, F\} mask bits. If wake-up is invoked by an interrupt that is disabled or masked the interrupt is not taken.

- Because debug events are WFI wake-up events, ARM recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

- Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

Using WFI to indicate an idle state on bus interfaces

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the WFI instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the OS Double Lock control, OSDLR_EL1.DLK, is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked on page H6-5088.

Note

In a PE that implements separate core and debug power domains, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see Power domains and debug on page H6-5081.
The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

**Pseudocode description of Wait For Interrupt**

The `WaitForInterrupt()` pseudocode procedure optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
D1.18 **Self-hosted debug**

The ARMv8-A architecture supports both of the following:

**Self-hosted debug**

The PE itself hosts a debugger. The debugger programs the PE to generate debug exceptions. Debug exceptions are accommodated in the ARMv8-A Exception model.

**External debug**

The PE is controlled by an external debugger. The debugger programs the PE to generate Halting debug events, that cause the PE to enter Debug state. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- **Debug exceptions**.
- **The PSTATE debug mask bit, D**.

For external debug, see part E.

D1.18.1 **Debug exceptions**

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Software Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

Chapter D2 _AArch64 Self-hosted Debug_ describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. The debug exception enable controls on page D2-1626 gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See _Enabling debug exceptions from the current Exception level and Security state_ on page D2-1629.

Debug exceptions are synchronous exceptions, and are accommodated in the ARMv8 Exception model.

--- **Note**

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See Chapter H1 _Introduction to External Debug_.

D1.18.2 **The PSTATE debug mask bit, D**

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the ARMv8 architecture provides a debug exception mask bit, PSTATE.D, that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.
PSTATE.D is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by PSTATE.D.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when PSTATE.D is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

Note
This differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.
D1.19 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See Appendix J3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events.

For more information, see Chapter D5 The Performance Monitors Extension.
D1.20 Interprocessing

Interprocessing is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:
• Remains unchanged.
• Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:
• Remains unchanged.
• Changes from AArch64 state to AArch32 state.

--- Note ---
If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

For the description of:
• Exception entry to an Exception level using AArch64, see Exception entry on page D1-1516.
• Exception return from an Exception level using AArch64 state, see Exception return on page D1-1533.
• Exception return to AArch32 state, see Exception return to an Exception level using AArch32 on page G1-3860.

--- Note ---
The description in Handling exceptions that are taken to an Exception level using AArch32 on page G1-3841 is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

The following sections describe the behavior associated with interprocessing.
• Register mappings between AArch32 state and AArch64 state.
• State of the general-purpose registers on taking an exception to AArch64 state on page D1-1613.
• SPSR, ELR, and AArch64 SP relationships on changing Execution state on page D1-1614.

D1.20.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:
• For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
• For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:
• The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
• In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

--- Note ---
System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.
For more information see the following subsections:

- Mapping of the general-purpose registers between the Execution states.
- Mapping of the SIMD and floating-point registers between the Execution states on page D1-1606.
- Mapping of the System registers between the Execution states on page D1-1607.

Mapping of the general-purpose registers between the Execution states

Table D1-77 shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register.

</tbody>
</table>

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. Figure D1-3 shows this mapping.

Figure D1-3 AArch64 state SIMD and floating-point register mappings
In AArch32 state, there are:
- 16 128-bit Q registers, Q0-Q15.
- 32 64-bit D registers, D0-D31.
- 32 32-bit S registers, S0-S31.

Smaller registers are packed into larger registers. Figure D1-4 shows this mapping.

Figure D1-4 AArch32 state SIMD and floating-point register mappings

In AArch32 state:
- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

Note
A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

Mapping of the System registers between the Execution states

ARMv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

Note
This model is different to the model for the general-purpose registers described in Mapping of the general-purpose registers between the Execution states on page D1-1605. In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. In Table D1-79 on page D1-1608 these banked registers are identified by footnotea. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. This means that when EL3 is implemented and is using AArch64, exactly the same registers are accessed in the following states:
- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.

This means that, architecturally, it is not possible to determine whether an AArch64 register is mapped onto the Secure instance of the corresponding AArch32 register, or onto the Non-secure instance of that register. When EL3 is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt as is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.
Note

Although the architecture does not require this, because it is not architecturally visible, ARM expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and will map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

- **IFAR**  
  This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.
- **DFAR**  
  This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

Table D1-79 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

a. AArch32 registers that are banked if EL3 is using AArch32.
b. These registers have overlapping register content. One or more bits of one register appear in the other register.
There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table D1-80 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

D1.20.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

If the general-purpose register was accessible from AArch32 state

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:
- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-82 shows which general-purpose registers can have their upper 32 bits set to zero.

<table>
<thead>
<tr>
<th>SCR_EL3.RW</th>
<th>HCR_EL2.RW or HCR.RWa</th>
<th>Registers when the target Exception level is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>X0-X30</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>_b</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>X0-X14, X16-X30</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>X0-X14</td>
</tr>
</tbody>
</table>

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted EL.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bit prevents its use, then as described in The effects of supporting fewer than four Exception levels on page D1-1618, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of SCR_EL3.RW is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.

Which general-purpose registers retain their state depends on both:
- The AArch64 state target Exception level.
The values of both:
- SCR_EL3.RW.
- HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-83 shows which general-purpose registers can retain their state.

**Table D1-83 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32**

<table>
<thead>
<tr>
<th>SCR_EL3.RW</th>
<th>HCR_EL2.RW or HCR.RWa</th>
<th>Registers when the target Exception level is:</th>
</tr>
</thead>

</tr>
<tr>
<td>1</td>
<td>0</td>
<td>X15</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>X15-X30</td>
</tr>
</tbody>
</table>

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted EL.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

**Note**
If EL2 is not implemented, or the SCR_EL3.NS bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels on page D1-1618*, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

**D1.20.3 SPSR, ELR, and AArch64 SP relationships on changing Execution state**

Table D1-84 shows the SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state.

**Table D1-84 SPSR and ELR mappings between AArch32 state and AArch64 state**

<table>
<thead>
<tr>
<th>AArch32 register</th>
<th>AArch64 register</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>SPSR_hyp</td>
<td>SPSR_EL2</td>
</tr>
<tr>
<td>ELR_hyp</td>
<td>ELR_EL2</td>
</tr>
</tbody>
</table>

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of ELR_EL2 are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.
The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- SPSR_abt.
- SPSR_und.
- SPSR_irq.
- SPSR_fiq.

--- Note ---
- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.
- If EL1 does not support execution in AArch32 state then these registers are RES0.

On exception entry to an Exception level using AArch64 from an Exception level using AArch32, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at that Exception level retain the state that they had before AArch32 execution. This applies to the following registers:

- SP_EL0.
- SP_EL1.
- SP_EL2.
- ELR_EL1.
D1.21 The effect of implementation choices on the programmers' model

Three of the implementation choices in ARMv8 are:

- The number of Exception levels implemented.
- Which Exception levels support AArch32 and which Exception levels support AArch64.
- Whether SIMD and floating-point support is implemented.

The following subsections give more information about how these choices affect the programmers’ model:

- Implication of Exception levels implemented.
- Support for Exception levels and Execution states on page D1-1617.
- Implementations not including Advanced SIMD and floating-point instructions on page D1-1618.
- The effects of supporting fewer than four Exception levels on page D1-1618.

D1.21.1 Implication of Exception levels implemented

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also Implementations not including Advanced SIMD and floating-point instructions on page D1-1618 and The effects of supporting fewer than four Exception levels on page D1-1618.

For an implementation that includes all of the Exception levels Figure D1-5 shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. Figure D1-5 applies regardless of whether EL3 also supports use of AArch32.

![Figure D1-5 ARMv8-A security model when EL3 is using AArch64](image)

† AArch64 permitted only if EL1 is using AArch64
‡ AArch64 permitted only if EL2 is using AArch64

Figure D1-5 ARMv8-A security model when EL3 is using AArch64
The possible combinations of Exception levels are as follows:

- EL0, EL1, and EL2. The implementation supports only Non-secure state.

- EL0, EL1, and EL3. The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
  - If EL3 is using AArch64, the Exception levels and Execution states are as shown in Figure D1-5 on page D1-1616 with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
  - If EL3 is using AArch32, the Exception levels and Execution states are as shown in Figure G1-1 on page G1-3816 with EL2 removed and no Non-secure state virtualization of EL1 and EL0.

- EL0 and EL1 only. The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see Behavior when only EL1 and EL0 are implemented on page D1-1619.

- EL0, EL1, EL2, and EL3, as described in this section.

For more information, see The effects of supporting fewer than four Exception levels on page D1-1618.

### D1.21.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in Interprocessing on page D1-1604, an implementation of the ARM architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the ARMv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. ARM intends to license only a subset of the possible combinations. Table D1-85 shows the combinations of Exception levels and Execution states that are currently licensed.

<table>

</tbody>
</table>
D1.21.3 Implementations not including Advanced SIMD and floating-point instructions

In general, ARMv8-A requires the inclusion of the Floating-point and Advanced SIMD instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets, ARM might produce or license an ARMv8-A implementation that does not provide any support for Floating-point and Advanced SIMD instructions. In such an implementation:

In AArch64 state
- The CPACR_EL1.FPEN field is RES0.
- The CPTR_EL2.TFP bit is RES1.
- The CPTR_EL3.TFP bit is RES1.
- Each of the ID_AA64PFR0_EL1.{AdvSIMD, FP} fields is 0b1111.

D1.21.4 The effects of supporting fewer than four Exception levels

The effect of implementation choices on the programmers' model on page D1-1616 defines the permitted combinations of Exception levels in an ARMv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:
- No interrupts are routed to these Exception levels.
- No traps that target these Exception levels are active
- All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
- There is no support for address translation from these Exception levels.
- Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in Illegal return events from AArch64 state on page D1-1534.
- Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

Note
If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

Behavior when EL2 is not implemented

If EL2 is not implemented and EL3 is implemented:
- If EL1 can use AArch32 then the following registers are not RES0:
  - DACR32_EL2.
  - IFSR32_EL2.
  - FPEXC32_EL2.
  - DBGVCR32_EL2.
- The VMPIDR_EL2 and VPIDR_EL2 are RO and:
  - VMPIDR_EL2 takes the value of MPIDR_EL1.
  - VPIDR_EL2 takes the value of MIDR_EL1.
• Behavior is consistent with the HCR_EL2.RW bit taking the value of the SCR_EL3.RW bit for all purposes other than reading the HCR_EL2.

• Virtual interrupts are disabled.

• The following address translation and TLB invalidation instructions are UNDEFINED:
  — AT S1E2R and AT S1E2W.
  — TLBI VAE2, TLBI VALE2, TLBI VAE2IS, TLBI VALE2IS, TLBI ALLE2, TLBI ALLE2IS.

  Note
  No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.

• The SCR_EL3.HCE bit is res0.

• The CNTHCTL_EL2[1:0] bits are treated as if they have the value 0b11 for all purposes other than reading the CNTHCTL_EL2 register.

Behavior when EL3 is not implemented

If EL3 is not implemented and EL2 is implemented, then:

• All memory transactions can only access a single physical memory address space.

• The PE behaves as if the value of the SCR_EL3.NS bit is 1, even though the SCR_EL3 is not accessible.

This means that if the PE is part of a system that supports two Security states, it behaves as if it is in Non-secure state, and can only access Non-secure memory.

Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the PE behaves as if the value of the SCR_EL3.NS bit is 1 or the PE behaves as if the value of the SCR_EL3.NS bit is 0.

This means that if the PE is part of a system that supports two Security states:

• If it behaves as if the value of the SCR_EL3.NS bit is 1, it can only access Non-secure memory.

• If it behaves as if the value of the SCR_EL3.NS bit is 0, it can access both Secure memory and Non-secure memory.

  Note
  The behavior described in this subsection still applies if EL1 is configured to use AArch32.

• The implementation can provide a configuration input that determines, from reset, whether the it behaves as if the value of the SCR_EL3.NS bit is 1, or as if the value of the SCR_EL3.NS bit is 0.
D1 The AArch64 System Level Programmers’ Model
D1.21 The effect of implementation choices on the programmers’ model
Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

**Introductory information**
- *About debug exceptions* on page D2-1623.
- *The debug exception enable controls* on page D2-1626.

**The debug Exception model**
- *Routing debug exceptions* on page D2-1627.
- *Enabling debug exceptions from the current Exception level and Security state* on page D2-1629.
- *The effect of powerdown on debug exceptions* on page D2-1631.
- *Summary of the routing and enabling of debug exceptions* on page D2-1632.
- *Pseudocode description of debug exceptions* on page D2-1634.

**The debug exceptions**
- *Software Breakpoint Instruction exceptions* on page D2-1636.
- *Breakpoint exceptions* on page D2-1638.
- *Watchpoint exceptions* on page D2-1656.
- *Vector Catch exceptions* on page D2-1670.
- *Software Step exceptions* on page D2-1671.

**Synchronization requirements**

The behavior of self-hosted debug after changes to system registers, or after changes to the authentication interface, but before a *Context Synchronization Operation* (CSO) guarantees the effects of the changes:
- *Synchronization and debug exceptions* on page D2-1686.
Note

Definition of a debugger

Within this chapter, \textit{debugger} means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective the debug services are the debugger.
D2.1 About debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in an AArch64 translation regime are:

- **Software Breakpoint Instruction exceptions.**
- **Breakpoint exceptions**, generated by hardware breakpoints.
- **Watchpoint exceptions** on page D2-1624, generated by hardware watchpoints.
- **Software Step exceptions** on page D2-1624.

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See *Routing debug exceptions* on page D2-1627. Chapter G2 describes the debug exceptions that can be generated in an AArch32 translation regime.

*Vector Catch exceptions* are exceptions that are never generated in an AArch64 translation regime but can be generated in an AArch32 stage 1 translation regime and routed to EL2 using AArch64. *Vector Catch exceptions* on page D2-1670 describes the behavior for this case.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1629. Software Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.
   
   All of the debug exceptions except for Software Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See *The debug exception enable controls* on page D2-1626.

---

**Note**

If *halting is allowed* and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-4977.

---

The following list summarizes each of the debug exceptions:

### Software Breakpoint Instruction exceptions

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Software Breakpoint Instruction exception.

**PE behavior**

Software Breakpoint Instruction exceptions cannot be masked. The PE takes Software Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see *Software Breakpoint Instruction exceptions* on page D2-1636.

### Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.
The ARMv8-A architecture supports the following types of hardware breakpoint for use in an AArch64 stage 1 translation regime:

- **Address.** Comparisons are made with the virtual address of each instruction in the program flow.
- **Context:**
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1.
  - VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

### PE behavior

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions* on page D2-1638.

### Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint, if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

### PE behavior

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions* on page D2-1656.

### Vector Catch exceptions

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See *Vector Catch exceptions* on page D2-1670.

### Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.
After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

**PE behavior**

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see *Software Step exceptions* on page D2-1671.

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Software Breakpoint Instruction exceptions</td>
<td>Takes the exception</td>
<td>Takes the exception</td>
</tr>
<tr>
<td>Breakpoint exceptions</td>
<td>Takes the exception(^a)</td>
<td>Ignored</td>
</tr>
<tr>
<td>Watchpoint exceptions</td>
<td>Takes the exception(^a)</td>
<td>Ignored</td>
</tr>
<tr>
<td>Vector Catch exceptions</td>
<td>Takes the exception</td>
<td>Ignored</td>
</tr>
<tr>
<td>Software Step exceptions</td>
<td>Takes the exception</td>
<td>Not applicable(^b)</td>
</tr>
</tbody>
</table>

\(^a\) If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 *Debug State*.

\(^b\) Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.
D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Software Breakpoint Instruction exceptions**
- None. Software Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**
- MDSCR_EL1.MDE, plus an enable control for each breakpoint, DBGBCR<n>_EL1.E.

**Watchpoint exceptions**
- MDSCR_EL1.MDE, plus an enable control for each watchpoint, DBGWCR<n>_EL1.E.

**Vector Catch exceptions**
- MDSCR_EL1.MDE.

**Software Step exceptions**
- MDSCR_EL1.SS.

In addition, for all debug exceptions other than Software Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1629.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Software Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
D2.3 Routing debug exceptions

Debug exceptions are usually routed to EL1. However:

- If EL2 is implemented, the routing of debug exceptions taken from Non-secure state depends on MDCR_EL2.TDE:
  - 1 Debug exceptions taken from Non-secure state are routed to EL2.
  - 0 As follows:
    - Debug exceptions taken from Non-secure EL1 and EL0 are routed to Non-secure EL1.
    - Software Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
    - All other debug exceptions are disabled from EL2 using AArch64.

_________ Note ___________

If HCR_EL2.TGE is 1, MDCR_EL2.TDE is treated as being 1 except for a direct read of MDCR_EL2.

Table D2-2 shows this.

Table D2-2 The effect of the TGE and TDE controls on debug exception routing

<table>
<thead>
<tr>
<th>HCR_EL2.TGE</th>
<th>MDCR_EL2.TDE</th>
<th>Debug exceptions taken from Non-secure state are routed to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Non-secure EL1&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>EL2</td>
</tr>
<tr>
<td>1</td>
<td>X</td>
<td>EL2</td>
</tr>
</tbody>
</table>

<sup>a</sup> Software Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

_________ Note ___________

If EL2 is not implemented, the PE behaves as if both HCR_EL2.TGE and MDCR_EL2.TDE are 0.

- If EL3 is implemented, Software Breakpoint Instruction exceptions taken from EL3 are routed to EL3. All other debug exceptions are disabled from EL3 using AArch64.

Either EL1 or EL2 is the debug target exception level, EL<sub>D</sub>. That is, EL<sub>D</sub> is EL1 unless EL2 is implemented and MDCR_EL2.TDE is 1 and the debug exception is taken from Non-secure state, when EL<sub>D</sub> is EL2.

The following tables show the routing of debug exceptions:

Table D2-3 Routing when both EL3 and EL2 are implemented

<table>
<thead>
<tr>
<th>MDCR_EL2.TDE&lt;sup&gt;a&lt;/sup&gt;</th>
<th>EL&lt;sub&gt;D&lt;/sub&gt; when executing in:</th>
<th>Non-secure:</th>
<th>Secure:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>
<td>EL1</td>
<td>EL2</td>
</tr>
<tr>
<td>0</td>
<td>EL1</td>
<td>EL1</td>
<td>EL1</td>
</tr>
<tr>
<td>1</td>
<td>EL2</td>
<td>EL2</td>
<td>EL2</td>
</tr>
</tbody>
</table>

<sup>a</sup> If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2.

<sup>b</sup> EL<sub>D</sub> is EL1. However, all debug exceptions other than Software Breakpoint Instruction exceptions are disabled, and Software Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
D2.3 Routing debug exceptions

Table D2-4 Routing when EL3 is implemented and EL2 is not implemented

<table>
<thead>
<tr>
<th>ELD when executing in:</th>
<th>Non-secure:</th>
<th>Secure:</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>EL1</td>
<td>EL1</td>
</tr>
<tr>
<td>EL1</td>
<td>EL1</td>
<td>EL1</td>
</tr>
<tr>
<td>EL1</td>
<td>EL1</td>
<td>EL1(^a)</td>
</tr>
</tbody>
</table>

\(^a\) EL0 is EL1. However, all debug exceptions other than Software Breakpoint Instruction exceptions are disabled, and Software Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

Table D2-5 Routing when EL3 is not implemented and EL2 is implemented

<table>
<thead>
<tr>
<th>MDCR_EL2.TDE(^a)</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>EL1</td>
<td>EL1</td>
<td>EL1 (^b)</td>
</tr>
<tr>
<td>1</td>
<td>EL2</td>
<td>EL2</td>
<td>EL2</td>
</tr>
</tbody>
</table>

\(^a\) If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2.

\(^b\) EL0 is EL1. However, all debug exceptions other than Software Breakpoint Instruction exceptions are disabled, and Software Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

D2.3.1 Pseudocode description of routing debug exceptions

DebugTarget() returns the current debug target Exception level.

```c
// DebugTarget()
// =============

bits(2) DebugTarget()
    secure = IsSecure();
    return DebugTargetFrom(secure);
```

DebugTargetFrom() returns the debug target Exception level for the specified Security state.

```c
// DebugTargetFrom()
// =============

// Returns the debug exception target Exception level

bits(2) DebugTargetFrom(boolean secure)
    if HaveEL(EL2) && !secure then
        if ELUsingAArch32(EL2) then
            route_to_el2 = (HDCR.TDE == '1' || HCR.TGE == '1');
        else
            route_to_el2 = (MDCR_EL2.TDE == '1' || HCR_EL2.TGE == '1');
        else
            route_to_el2 = FALSE;
    if route_to_el2 then
        target = EL2;
    else
        if HaveEL(EL3) && HighestELUsingAArch32() && secure then
            target = EL3;
        else
            target = EL1;
    return target;
```
D2.4 Enabling debug exceptions from the current Exception level and Security state

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- EDPRSR.DLK is 0.
- The debug exception is enabled from the current Exception level.
- The debug exception is enabled from the current Security state.

Table D2-6 shows when debug exceptions are enabled from the current Exception level. In the table, ELD is the Exception level that Table D2-3 on page D2-1627 defines.

Table D2-6 Whether debug exceptions are enabled from the current Exception level

<table>
<thead>
<tr>
<th>Current Exception level</th>
<th>Software Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any Exception level that is higher than ELD(^a)</td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>ELD</td>
<td>Enabled</td>
<td>Disabled if either of the following is true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The Local (kernel) Debug Enable bit, MDSCR_EL1.KDE, is 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The Debug exception mask bit, PSTATE.D, is 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise enabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This means that a debugger must explicitly enable these debug exceptions from ELD by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0.</td>
</tr>
<tr>
<td>Any Exception level that is lower than ELD</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

\(^a\) This includes EL3. EL3 is always higher than ELD.

--- Note ---

PSTATE.D is set to 1 at reset and on exception entry.

Table D2-7 shows when debug exceptions are enabled from the current Security state.

Table D2-7 Whether debug exceptions are enabled from the current Security state

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>Software Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>Secure</td>
<td>Enabled</td>
<td>Disabled if MDCR_EL3.SDD is 1. See Disabling debug exceptions from Secure state on page D2-1630. Otherwise enabled.</td>
</tr>
</tbody>
</table>

---
D2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the Secure Debug Disable bit, MDCR_EL3.SDD, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Software Breakpoint Instruction exceptions.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

--- Note ---
- If the boot software executed when reset is deasserted sets MDCR_EL3.SDD to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
- The PE cannot take a debug exception unless it is enabled from the current Exception level. See Table D2-6 on page D2-1629.
- If either the OS lock or the OS double-lock is locked, debug exceptions other than Software Breakpoint Instruction exceptions are disabled.
- If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if MDCR_EL3.SDD is 0.

D2.4.2 Pseudocode description of enabling debug exceptions

AArch64.GenerateDebugExceptions() determines whether debug exceptions other than Software Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

```c
// AArch64.GenerateDebugExceptions()
// =================================
boolean AArch64.GenerateDebugExceptions()
return AArch64.GenerateDebugExceptionsFrom(PSTATE.EL, IsSecure(), PSTATE.D);
```

AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions other than Software Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

```c
// AArch64.GenerateDebugExceptionsFrom()
// =====================================
boolean AArch64.GenerateDebugExceptionsFrom(bits(2) from, boolean secure, bit mask)
if OSLSR_EL1.OSLK == '1' || DoubleLockStatus() || Halted() then
return FALSE;
route_to_el2 = HaveEL(EL2) && !secure && (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1');
if HaveEL(EL3) && secure then
enabled = MDCR_EL3.SDD == '0' && from != EL3;
else
enabled = TRUE;
target = if route_to_el2 then EL2 else EL1;
if from == target then
enabled = enabled && MDSCR_EL1.KDE == '1' && mask == '0';
return enabled;
```
D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-5086 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Software Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and EDPRSR.DLK is 0.

Software Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and EDPRSR.DLK.
D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

Software Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. Table D2-8 shows the routing of these. In the table, n/a means not applicable.

Table D2-8 Routing of Software Breakpoint Instruction exceptions

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>MDCR_EL2.TDE&lt;sup&gt;a&lt;/sup&gt;</th>
<th>EL&lt;sub&gt;D&lt;/sub&gt; when enabled from:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>EL0</td>

<tr>
<td>Secure</td>
<td>X</td>
<td>Secure EL1</td>
</tr>
<tr>
<td>Non-secure</td>
<td>0</td>
<td>Non-secure EL1</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>EL2</td>
</tr>
</tbody>
</table>

<sup>a</sup> If EL2 is not implemented, behavior is as if this is 0. Otherwise, if the value of HCR_EL2.TGE is 1, MDCR_EL2.TDE is treated as being 1 other than for a direct read of MDCR_EL2.

All other debug exceptions

Table D2-9 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table D2-9 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

</table>

<sup>a</sup> The value of (OSLSR_EL1.OSLK OR EDPRSR.DLK).

<sup>b</sup> If EL3 is not implemented, behavior is as if this is 0.
c. If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2. If EL2 is not implemented, behavior is as if TDE is 0.
D2.7  Pseudocode description of debug exceptions

DebugFault() returns a FaultRecord object that indicates that a memory access has generated a debug exception:

```c
// AArch64.DebugFault()
// ---------------------
FaultRecord AArch64.DebugFault(AccType acctype, boolean iswrite)

    ipaddress = bits(48) UNKNOWN;
    level = integer UNKNOWN;
    extflag = bit UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch64.CreateFaultRecord(Fault_Debug, ipaddress, level, acctype, iswrite, extflag, secondstage, s2fs1walk);
```

The Abort() function processes FaultRecord objects, as described in Abort exceptions on page D3-1720, and generates a debug exception.

Abort() calls one of the following:

```c
// AArch64.BreakpointException()
// -----------------------------
AArch64.BreakpointException(FaultRecord fault)

    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_Breakpoint, fault, vaddress);

    if PSTATE.EL == EL2 || route_to_el2 then
       AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
       AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

// AArch64.WatchpointException()
// -----------------------------
AArch64.WatchpointException(bits(64) vaddress, FaultRecord fault)

    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = AArch64.AbortSyndrome(Exception_Watchpoint, fault, vaddress);

    if PSTATE.EL == EL2 || route_to_el2 then
       AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
       AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

// AArch64.VectorCatchException()
// -----------------------------
AArch64.VectorCatchException()

    // Vector Catch taken from EL0 or EL1 to EL2. This can only be called when debug exceptions are
    // being routed to EL2, as Vector Catch is a legacy debug event.
```
AArch64.VectorCatchException(FaultRecord fault)
    assert PSTATE.EL != EL2;
    assert HaveEL(EL2) && !IsSecure() && (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1');
    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;
    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_VectorCatch, fault, vaddress);
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);

// AArch64.SoftwareStepException()
// ------------------------------

AArch64.SoftwareStepException()
    assert PSTATE.EL != EL3;
    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));
    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;
    exception = ExceptionSyndrome(Exception_SoftwareStep);
    if SoftwareStep_DidNotStep() then
        exception.syndrome<24> = '0';
    else
        exception.syndrome<24> = '1';
        exception.syndrome<6> = if SoftwareStep_SteppedEX() then '1' else '0';
    if PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
D2.8 Software Breakpoint Instruction exceptions

This section describes Software Breakpoint Instruction exceptions in an AArch64 translation regime.

It contains the following subsections:
• About Software Breakpoint Instruction exceptions.
• Breakpoint instruction in the A64 instruction set.
• Exception syndrome information and preferred return address.
• Pseudocode description of Software Breakpoint Instruction exceptions on page D2-1637.

D2.8.1 About Software Breakpoint Instruction exceptions

A breakpoint is a debug event that results from the execution of an instruction, based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Software Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page D2-1638 describes hardware breakpoints.

There is no enable control for Software Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Software Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:
• The current Exception level.
• The current Security state.
• Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

Note
• The debug target exception level, EL_D, is the Exception level that debug exceptions are targeting. Routing debug exceptions on page D2-1627 describes how EL_D is derived.
• Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-83.

D2.8.2 Breakpoint instruction in the A64 instruction set

The breakpoint instruction is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see BRK on page C6-447.

D2.8.3 Exception syndrome information and preferred return address

See the following:
• Exception syndrome information.
• Preferred return address on page D2-1637.

Exception syndrome information

On taking a Software Breakpoint Instruction exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:
• ESR_EL1.
• ESR_EL2.
• ESR_EL3.
Note
Software Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

Table D2-10 shows the information that the PE records.

Table D2-10 Information recorded in the ESR_ELx

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0x3C for an A64 BRK instruction.</td>
</tr>
<tr>
<td></td>
<td>• 0x38 for an A32 or T32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0 for a 16-bit T32 BKPT instruction.</td>
</tr>
<tr>
<td></td>
<td>• 1 for an A64 BRK instruction, or an A32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td>ISS[24:16]</td>
</tr>
<tr>
<td></td>
<td>ISS[15:0]</td>
</tr>
</tbody>
</table>

Note
• If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Software Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
• For information about how debug exceptions can be routed to EL2, see Routing debug exceptions on page D2-1627.

Preferred return address
The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Software Breakpoint Instruction exceptions

AArch64.SoftwareBreakpoint() generates a Software Breakpoint Instruction exception that is taken to AArch64 state.

```c
// AArch64.SoftwareBreakpoint()
// ---------------------------------------------
AArch64.SoftwareBreakpoint(bits(16) immediate)
route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
(HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));
bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
exception = ExceptionSyndrome(Exception_SoftwareBreakpoint);
expection.syndrome<15:0> = immediate;
if UInt(PSTATE.EL) > UInt(EL1) then
    AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
elsif route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```
D2.9  Breakpoint exceptions

This section describes Breakpoint exceptions in an AArch64 stage 1 translation regime.

The PE is using an AArch64 stage 1 translation regime when it is executing at either:

• An Exception level that is using AArch64.
• EL0 using AArch32 when EL1 is using AArch64.

It contains the following subsections:

• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page D2-1639.
• Execution conditions that a breakpoint generates Breakpoint exceptions for on page D2-1645.
• Instruction address comparisons on page D2-1646.
• Context comparisons on page D2-1648.
• Usage constraints on page D2-1648.
• Exception syndrome information and preferred return address on page D2-1650.
• Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-1651.

D2.9.1  About Breakpoint exceptions

A breakpoint is a debug event that results from the execution of an instruction, based on either:

• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint exceptions are generated by Breakpoint debug events. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Software Breakpoint Instruction exceptions on page D2-1636.

An implementation can include between 2-16 hardware breakpoints. ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

• The Breakpoint Control Register, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
• The Breakpoint Value Register, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, that is one of:
  — An instruction virtual address.
  — A Context ID.
  — A VMID value.
  — A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:

• DBGBCR1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
• DBGBCR2_EL1 and DBGBVR2_EL1 are for breakpoint number two.
• ...
• ...
• DBGBCR<n>_EL1 and DBGBVR<n>_EL1 are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.
For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<n>_EL1.E, is 1.
- The conditions specified in the DBGBCR<n>_EL1 are met.
- The comparison with the value held in the DBGBVR<n>_EL1 is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:
- Whether the instruction passes its condition code check.
- The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:
- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

--- Note ---

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

---

The debug exception enable controls on page D2-1626 describes the enable controls for Breakpoint debug events.

### D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - A Context ID match, with the value held in the CONTEXTIDR_EL1.
  - A VMID match, with the VMID value held in the VTTBR_EL2.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

ID_AA64DFR0_EL1.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:
- Used in isolation. In this case the breakpoint is called an Unlinked breakpoint.
- Enabled for linking to another breakpoint. In this case the breakpoint is called a Linked breakpoint.
By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a Linked Address Match breakpoint.
2. Program breakpoint number five to be a Linked Context ID Match breakpoint.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The Breakpoint Type field for a breakpoint, DBGBCR<n>_EL1.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

Figure D2-1 shows all of the possible breakpoint types that an AArch64 stage 1 translation regime supports, and their associated BT field values.

![Figure D2-1](image)

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See Specifying the halfword-aligned address that an Address breakpoint matches on on page D2-1647.

**Note**

AArch32 stage 1 translation regimes support two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, BT == 0b0010 and BT == 0b0101. For information about these, see Chapter G2 AArch32 Self-hosted Debug. These types are reserved in an AArch64 stage 1 translation regime. See Reserved BT values on page D2-1648.

**Rules for linking breakpoints**

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGCR<n>_EL1.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:

- DBGCR<n>_EL1.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions that a breakpoint generates Breakpoint exceptions on page D2-1645.
- DBGCR<n>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.

Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.

Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.

If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page D2-1650.

If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.

Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

**Note**

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page D2-1656 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure D2-2 on page D2-1642 shows an example of permitted breakpoint and watchpoint linking.
In Figure D2-2, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn_EL1.BT**

The following list provides more detail about each breakpoint type:

**0b0000, Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- **DBGBCR<n>_EL1.(SSC, HMC, PMC)**. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for on page D2-1645*.

- A successful address match, as described in *Instruction address comparisons on page D2-1646*.

**DBGBCR<n>_EL1.LBN** for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>_EL1.(SSC, HMC, PMC) for this breakpoint.** These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions that a breakpoint generates Breakpoint exceptions for on page D2-1645.

- A successful address match defined by this breakpoint, as described in Instruction address comparisons on page D2-1646.

- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

**DBGBCR<n>_EL1.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.**

0b0010, Unlinked Context ID Match breakpoint

**BT == 0b0010** is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>_EL1.(SSC, HMC, PMC).** These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions that a breakpoint generates Breakpoint exceptions for on page D2-1645.

- A successful Context ID match, as described in Context comparisons on page D2-1648.

**DBGBCR<n>_EL1.(LBN, BAS) for this breakpoint are ignored.**

0b0011, Linked Context ID Match breakpoint

**BT == 0b0011** is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.

- Generation of a Breakpoint exception depends on both:
  
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Instruction address comparisons on page D2-1646.
  
  - A successful Context ID match defined by this breakpoint, as described in Context comparisons on page D2-1648.

- Generation of a Watchpoint exception depends on both:
  
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Data address comparisons on page D2-1659.
  
  - A successful Context ID match defined by this breakpoint, as described in Context comparisons on page D2-1648.

**DBGBCR<n>_EL1.(LBN, SSC, HMC, BAS, PMC) for this breakpoint are ignored.**

0b0100, Unlinked Address Mismatch breakpoint

**BT == 0b0100** is a reserved value in an AArch64 stage 1 translation regime. See Reserved BT values on page D2-1648.

**0b0100, Unlinked Address Mismatch breakpoint on page G2-3975** describes the behavior of Address Mismatch breakpoints in an AArch32 stage 1 translation regime.

0b0101, Linked Address Mismatch breakpoint

**BT == 0b0101** is a reserved value in an AArch64 stage 1 translation regime. See Reserved BT values on page D2-1648.

**0b0101, Linked Address Mismatch breakpoint on page G2-3976** describes the behavior of Address Mismatch breakpoints in an AArch32 stage 1 translation regime.
0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
  • The breakpoint is not a context-aware breakpoint.
  • EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
  • `DBGBCR<n>_EL1.{SSC, HMC, PMC}`. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions that a breakpoint generates Breakpoint exceptions for on page D2-1645.
  • A successful VMID match, as described in Context comparisons on page D2-1648.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
  • The breakpoint is not a context-matching breakpoint.
  • EL2 is not implemented.

For context-aware breakpoints, either:
  • This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
  • Generation of a Breakpoint exception depends on both:
    — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Instruction address comparisons on page D2-1646.
    — A successful VMID match defined by this breakpoint, as described in Context comparisons on page D2-1648.

  • Generation of a Watchpoint exception depends on both:
    — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Data address comparisons on page D2-1659.
    — A successful VMID match defined by this breakpoint, as described in Context comparisons on page D2-1648.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
  • The breakpoint is not a context-aware breakpoint.
  • EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:
  • `DBGBCR<n>_EL1.{SSC, HMC, PMC}`. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See Execution conditions that a breakpoint generates Breakpoint exceptions for on page D2-1645.
  • A successful Context ID match.
  • A successful VMID match.

  Context comparisons on page D2-1648 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:
  • The breakpoint is not a context-aware breakpoint.
  • EL2 is not implemented.
For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or
  Linked watchpoints link to it.

- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that
    links to this breakpoint, see Instruction address comparisons on page D2-1646.
  - A successful Context ID match defined by this breakpoint.
  - A successful VMID match defined by this breakpoint.

- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this
    breakpoint, see Data address comparisons on page D2-1659.
  - A successful Context ID match defined by this breakpoint.
  - A successful VMID match defined by this breakpoint.

_Context comparisons on page D2-1648 describes the requirements for a successful Context ID
match and a successful VMID match by this breakpoint._

DBGBCR\langle n\rangle_EL1.\{LBN, SSC, HMC, BAS, PMC\} for this breakpoint are ignored.

---

D2.9.3 **Execution conditions that a breakpoint generates Breakpoint exceptions for**

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution
conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE
is executing at EL0 in Secure state.

DBGBCR\langle n\rangle_EL1.\{SSC, HMC, PMC\} defines the execution conditions the breakpoint generates Breakpoint
exceptions for, as follows:

**Security State Control, SSC**

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in
Non-secure state, or in both Security states. The comparison is made with the Security state of the
PE, not the NS attribute of the physical instruction fetch address.

**Higher Mode Control, HMC, and Privileged Mode Control, PMC**

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint
exceptions in.

Table D2-11 on page D2-1646 shows the valid combinations of the values of HMC, SSC, and PMC, and for each
combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

**Y** or **-**

Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row:

**Y** Can generate Breakpoint exceptions in that Exception level.

**-** Cannot generate Breakpoint exceptions in that Exception level.
Res  Means that the combination of HMC, SSC, and PMC is reserved. See Reserved 
DBGBCR<\n>_EL1.\{HMC, SSC, PMC\} values on page D2-1649.

Note: Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See Reserved 
DBGBCR<\n>_EL1.\{HMC, SSC, PMC\} values on page D2-1649.

D2.9.4 Instruction address comparisons

An address comparison is successful if bits [48:2] of the current instruction address are equal to 
DBGBVR<\n>_EL1[48:2].

Note:

DBGBVR<\n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. 
DBGBVR<\n>_EL1[1:0] are RES0 and are ignored.
Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger can program the Byte Address Selection field, DBGBMR<ν>_EL1.BAS, so that the address comparison is successful on one of:

• The whole word starting at address DBGBVR<ν>_EL1[48:2]:00.
• The halfword starting at address DBGBVR<ν>_EL1[48:2]:00.
• The halfword starting at address ((DBGBVR<ν>_EL1[48:2]:00) + 2).

This makes it possible to breakpoint on T32 instructions.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in an AArch64 stage 1 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

To breakpoint on an A64 instruction, ARM recommends that the debugger programs DBGBMR<ν>_EL1.BAS so that the breakpoint generates Breakpoint exceptions on the whole word starting at address DBGBVR<ν>_EL1[48:2]:00. The BAS field value for this is 0b1111.

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBMR<ν>_EL1.BAS is RES1.

Figure D2-3 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

• A column showing the row number, on the left.
• An instruction set and instruction size table.
• A location of instruction figure.
• A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBMR<ν>_EL1.BAS programmed as either 0b0111 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.
No Means that the breakpoint does not generate a Breakpoint exception.
UNP Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page D2-1650.

0 means the word-aligned address held in the DBGBVR<ν>_EL1[48:2]:00. The other locations are as follows:

• -2 means ((DBGBVR<ν>_EL1[48:2]:00) – 2).
• -1 means ((DBGBVR<ν>_EL1[48:2]:00) – 1).
• ... ...
• +5 means ((DBGBVR<ν>_EL1[48:2]:00) + 5).

The solid areas show the location of the instruction.

Figure D2-3 Summary of BAS field meanings for Address Match breakpoints
**D2.9.5 Context comparisons**

A context comparison is successful if, depending on the breakpoint type set by `DBGBCR<n>_EL1.BT`, one of the following is true:

- The current Context ID value is equal to `DBGBVR<n>_EL1[31:0]`.
- The current VMID value is equal to `DBGBVR<n>_EL1[39:32]`.
- The current Context ID value is equal to `DBGBVR<n>_EL1[31:0]` and the current VMID value is equal to `DBGBVR<n>_EL1[39:32]`.

Context breakpoints do not generate Breakpoint exceptions when execution is in EL2 using either Execution state, or when execution is in EL3 using AArch64.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:

- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

---

**Note**

- For all Context breakpoints, `DBGBCR<n>_EL1.BAS` is `RES1` and is ignored.
- For Linked Context breakpoints, `DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC}` are `RES0` and are ignored.

---

**D2.9.6 Usage constraints**

See the following:

- Reserved `DBGBCR<n>_EL1.BT` values.
- Reserved `DBGBCR<n>_EL1.{HMC, SSC, PMC}` values on page D2-1649.
- Reserved `DBGBCR<n>_EL1.BAS` values on page D2-1649.
- Reserved `DBGBCR<n>_EL1.LBN` values on page D2-1650.
- Other usage constraints for Address breakpoints on page D2-1650.
- Other usage constraints for Context breakpoints on page D2-1650.

**Reserved DBGBCR<n>_EL1.BT values**

Table D2-12 shows when particular `DBGBCR<n>_EL1.BT` values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b001x</td>
<td>Context ID Match</td>
<td>For non context-aware breakpoints.</td>

</tr>
<tr>
<td>0b11xx</td>
<td>-</td>
<td>Always.</td>
</tr>
</tbody>
</table>

If an enabled breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct read of `DBGBCR<n>_EL1`.
For a direct read of DBGBCR<\text{n}>_EL1, if the reserved BT value:

- Has no function for any execution conditions, the value read back is UNKNOWN.
- Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<\text{n}>_EL1.{HMC, SSC, PMC} values**

Table D2-13 shows when particular combinations of DBGBCR<\text{n}>_EL1.{HMC, SSC, PMC} are reserved in an AArch64 stage 1 translation regime.

### Table D2-13 Reserved HMC, SSC, and PMC combinations

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero.</td>
<td>When both of EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>Combinations not included in Table D2-11 on page D2-1646.</td>
<td>Always</td>
</tr>
</tbody>
</table>

For all breakpoints except Linked Context breakpoints, if an enabled breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct read of DBGBCR<\text{n}>_EL1.{HMC, SSC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

- If the reserved combination does not have a function for other execution conditions:
  - The breakpoint must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct read of DBGBCR<\text{n}>_EL1.{HMC, SSC, PMC} returns UNKNOWN values.

Linked Context breakpoints ignore the values of HMC, SSC, and PMC. See *Other usage constraints for Context breakpoints* on page D2-1650.

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<\text{n}>_EL1.BAS values**

In an AArch64-only implementation, DBGBCR<\text{n}>_EL1.BAS for all breakpoints is RES1.

Otherwise:

- For all Context breakpoints, DBGBCR<\text{n}>_EL1.BAS is RES1 and is ignored.

- For all Address breakpoints:
  - The BAS field values 0b0x11 and 0b10x are reserved. A breakpoint programmed with 0b0x01 or 0b01xx must behave as if it is programmed with 0b0x11 or 0b11xx respectively.
  - The BAS field values 0b0x10 and 0b10xx are reserved. A breakpoint programmed with 0b0x10 or 0b10xx must behave as if it is programmed with 0b0x00 or 0b00xx respectively.
— The BAS field value 0b0000 is reserved. A breakpoint programmed with 0b0000 must behave either as if it is disabled, or programmed with 0b0011, 0b1100, or 0b1111.

Reserved DBGBCR<n>_EL1.LBN values

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

Other usage constraints for Address breakpoints

For all Address breakpoints:

• DBGBVR<n>_EL1[1:0] are RES0 and are ignored.

• If the implementation supports AArch32 state:
  — For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  — If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[48:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

For Unlinked Address breakpoints, DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints:

• If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:
  — Disabled, and DBGBCR<n>_EL1.LBN for it reads UNKNOWN.
  — Links to an UNKNOWN context-aware breakpoint. In this case, it generates Breakpoint exceptions and DBGBCR<n>_EL1.LBN indicates which context-aware breakpoint it has linked to.

• If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

Other usage constraints for Context breakpoints

For all Context breakpoints:

• Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

• DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Context breakpoints:

• DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

• If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.9.7 Exception syndrome information and preferred return address

See the following:

• Exception syndrome information on page D2-1651.

• Preferred return address on page D2-1651.
Exception syndrome information

On taking a Breakpoint exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- ESR_EL1.
- ESR_EL2.

--- Note ---

Breakpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-14 shows the information that the PE records.

<table>
<thead>
<tr>
<th>Table D2-14 Information recorded in the ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ESR_ELx field</strong></td>
</tr>
<tr>
<td>Exception Class, EC</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Instruction Length, IL</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
</tr>
<tr>
<td>ISS[5:0]</td>
</tr>
</tbody>
</table>

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

AArch64.BreakpointValueMatch() tests the value in DBGBVR<n>_EL1.

```java
// AArch64.BreakpointValueMatch()
// ===============

boolean AArch64.BreakpointValueMatch(integer n, bits(64) vaddress, boolean linked_to)

    // "n" is the identity of the breakpoint unit to match against
    // "vaddress" is the current instruction address, ignored if linked_to is TRUE and for Context matching breakpoints.
    // "linked_to" is TRUE if this is a call from StateMatch for linking.

    // If a non-existent breakpoint then it is CONSTRAINED UNPREDICTABLE whether this gives
    // no match or the breakpoint is mapped to another UNKNOWN implemented breakpoint.
    if n > UInt(ID_AA64DFR0_EL1.BRPs) then
        (c, n) = ConstrainUnpredictableInteger(0, UInt(ID_AA64DFR0_EL1.BRPs));
        assert c IN {Constraint_DISABLED, Constraint_UNKNOWN};
        if c == Constraint_DISABLED then return FALSE;

    // If this breakpoint is not enabled, it cannot generate a match. (This could also happen on a
    // call from StateMatch for linking.)
    if DBGBCR_EL1[n].E == '0' then return FALSE;

    context_aware = (n > UInt(ID_AA64DFR0_EL1.BRPs) - UInt(ID_AA64DFR0_EL1.CTX_CMPs));

    // If BT is set to a reserved type, behaves either as disabled or as a not-reserved type.
    type = DBGBCR_EL1[n].BT;
```
if (type == 'x1xx' ||
    (type != '0x0x' && !context_aware) ||
    (type == '1xxx' && !HaveEL(EL2))) then
  (c, type) = ConstrainUnpredictableBits();
assert c IN {Constraint_DISABLED, Constraint_UNKNOWN};
if c == Constraint_DISABLED then return FALSE;
// Otherwise the value returned by ConstrainUnpredictableBits must be a not-reserved value

// Determine what to compare against.
match_addr = type == '000x';
match_vmid = type == '10xx';
match_cid  = type == 'x01x';
linked     = type == 'xxx1';

// If this is a call from StateMatch, return FALSE if the breakpoint is not programmed for a
// VMID and/or context ID match, of if not context-aware. The above assertions mean that the
// code can just test for match_addr == TRUE to confirm all these things.
if linked_to & & (!linked || match_addr) then return FALSE;

// If called from BreakpointMatch return FALSE for Linked context ID and/or VMID matches.
if !linked_to & & linked & & match_addr then return FALSE;

// Do the comparison.
if match_addr then
  byte = UInt(vaddress[1:0]);
  if HaveAnyAArch32() then
    // T32 instructions can be executed at EL0 in an AArch64 translation regime.
    assert byte IN {0,2};  // "vaddress" is halfword aligned.
    byte_select_match = (DBGBCR_EL1[n].BAS<byte> == '1');
  else
    assert byte == 0;    // "vaddress" is word aligned
    byte_select_match = TRUE;  // DBGBCR_EL1[n].BAS<byte> is RES1
  top = AddrTop(vaddress);
  BVR_match = vaddress<top:2> == DBGBVR_EL1[n]<top:2> & & byte_select_match;
elsif match_cid then
  BVR_match = (PSTATE.EL IN {EL0,EL1} & & CONTEXTIDR_EL1 == DBGBVR_EL1[n]<31:0>);
if match_vmid then
  BXVR_match = (HaveEL(EL2) & & !IsSecure() & & PSTATE.EL IN {EL0,EL1} & &
    VTTBR_EL2.VMID == DBGBVR_EL1[n]<39:32>);
match = (!match_vmid || BXVR_match) & & (!match_addr || match_cid) || BVR_match;
return match;

AArch64.StateMatch() tests the values in DBGBCR<n>_EL1.{SSC, HMC, PMC} and, if the breakpoint links to a
Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, AArch64.StateMatch() tests the values in DBGWCR<n>_EL1.{SSC, HMC, PAC} and, if the
watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

// AArch64.StateMatch()
//=== ----------
// Determine whether a breakpoint or watchpoint is enabled in the current mode and state.

boolean AArch64.StateMatch(bits(2) SSC, bit HMC, bits(2) PxC, boolean linked, bits(4) LBN,
  boolean ispriv) {
  // "SSC", "HMC", "PxC" are the control fields from the DBGBCR[n] or DBGWCR[n] register.
  // "LBN" is the linked breakpoint number from the DBGBCR[n] or DBGWCR[n] register.
  // "ispriv" is valid for watchpoints, and selects between privileged and unprivileged accesses.
  // "linked" is TRUE if this is a linked breakpoint/watchpoint type.

  // If parameters are set to a reserved type, behaves either as disabled or not a reserved-type

if HaveAnyAArch32() && size == 4 then
  // Check second halfword
  // If the breakpoint address and BAS of an Address breakpoint match the address of the
  // second halfword of an instruction, but not the address of the first halfword, it is
  // CONSTRAINED UNPREDICTABLE whether or not this breakpoint generates a Breakpoint debug
  // event.
  match_i = AArch64.BreakpointValueMatch(n, vaddress + 2, linked_to);
  if !value_match && match_i then
value_match = ConstrainUnpredictableBool();
if vaddress<1> == '1' && DBGBCR_EL1[n].BAS == '1111' then
  // The above notwithstanding, if DBGBCR_EL1[n].BAS == '1111', then it is CONSTRAINED
  // UNPREDICTABLE whether or not a Breakpoint debug event is generated for an instruction
  // at the address DBGVR_EL1[n]+2.
  if value_match then value_match = ConstrainUnpredictableBool();

match = value_match && state_match && enabled;
return match;

AArch64.CheckBreakpoint() generates a Breakpoint exception if all of the following are true:

• MDSCR_EL1.MDE is 1.
• Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state on page D2-1629.
• All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page D2-1638.

--- Note ---
AArch64.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

// AArch64.CheckBreakpoint()
// ================
// Called before executing the instruction of length "size" bytes at "vaddress" in an AArch64 
// translation regime.
// The breakpoint can in fact be evaluated well ahead of execution, for example, at instruction 
// fetch. This is the simple sequential execution of the program.

FaultRecord AArch64.CheckBreakpoint(bits(64) vaddress, integer size)
  assert !ELUsingAArch32(S1TranslationRegime());
  assert (UsingAArch32() && size IN {2,4}) || size == 4;
  match = FALSE;
  for i = 0 to UInt(ID_AA64DFR0_EL1.BRPs)
    match_i = AArch64.BreakpointMatch(i, vaddress, size);
    match = match || match_i;
  if match && HaltOnBreakpointOrWatchpoint() then
    reason = DebugHalt_Breakpoint;
    Halt(reason);
  elsif match && MDSCR_EL1.MDE == '1' && AArch64.GenerateDebugExceptions() then
    accType = AccType_IFETCH;
    iswrite = FALSE;
    return AArch64.DebugFault(acctype, iswrite);
  else
    return AArch64.NoFault();

AArch64.BreakpointException() is called to generate a Breakpoint exception.

// AArch64.BreakpointException()
// ===============
AArch64.BreakpointException(FaultRecord fault)
  assert PSTATE.EL != EL3;
  route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
  (HCR_EL2.TGE == '1' || MDSCR_EL2.TDE == '1'));
  bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
vaddress = bits(64) UNKNOWN;
exception = AArch64.AbortSyndrome(Exception_Breakpoint, fault, vaddress);

if PSTATE.EL == EL2 || route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in an AArch64 stage 1 translation regime.

The PE is using an AArch64 stage 1 translation regime when it is executing at either:
• An Exception level that is using AArch64.
• EL0 using AArch32 when EL1 is using AArch64.

It contains the following subsections:
• About Watchpoint exceptions.
• Watchpoint types and linking of watchpoints on page D2-1657.
• Execution conditions a watchpoint generates Watchpoint exceptions for on page D2-1658.
• Data address comparisons on page D2-1659.
• Determining the memory location that caused a Watchpoint exception on page D2-1663.
• Watchpoint behavior on other instructions on page D2-1664.
• Usage constraints on page D2-1664.
• Exception syndrome information and preferred return address on page D2-1666.
• Pseudocode description of Watchpoint exceptions taken from AArch64 state on page D2-1667.

D2.10.1 About Watchpoint exceptions

A watchpoint is a debug event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:
1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRP shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:
• The Watchpoint Control Register, DBGWCR<n>_EL1. This contains controls for the watchpoint, for example an enable control.
• The Watchpoint Value Register, DBGWVR<n>_EL1. This holds the data address value used for watchpoint matching.

These registers are numbered, so that:
• DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
• DBGWCR2_EL2 and DBGWVR2_EL1 are for watchpoint number two.
• ...
• ...
• DBGWCR<n>_EL1 and DBGWVR<n>_EL1 are for watchpoint number n.

A watchpoint can:
• Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
• Link to a Linked Context breakpoint, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the Byte Address Select field, DBGWCR<n>_EL1.BAS, to select the bytes. See Programming a watchpoint with eight bytes or fewer on page D2-1660.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

A debugger uses the MASK field, DBGWCR<n>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint with eight or more bytes on page D2-1662.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields on page D2-1665.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>_EL1.E, is 1.
- The conditions specified in the DBGWCR<n>_EL1 are met.
- The comparison with the address held in the DBGWVR<n>_EL1 is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See Figure D2-2 on page D2-1642. See also Context comparisons on page D2-1648.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its condition code check.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

**Note**

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls on page D2-1626 describes the enable controls for Watchpoint debug events.

### D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case the watchpoint is called an **Unlinked watchpoint**.
- Enabled for linking to a Linked Context breakpoint. In this case the watchpoint is called a **Linked watchpoint**.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a **Linked VMID Match breakpoint**.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The Watchpoint Type field for a watchpoint, DBGWCR<\text{n}>_EL1.WT, controls whether the watchpoint is enabled for linking. If DBGWCR<\text{n}>_EL1.WT is 1, the watchpoint is enabled for linking.

**Rules for linking watchpoints**

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGWCR<\text{n}>_EL1.LBN, for the linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<\text{n}>_EL1.WT.\{SSC, HMC, PAC\} for the linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See **Execution conditions a watchpoint generates Watchpoint exceptions for**.
  - DBGBCR<\text{n}>_EL1.\{SSC, HMC, PMC\} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONstrained UNPredictable. See **Usage constraints** on page D2-1664.
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

**Note**

Multiple Address breakpoints can also link to a single Linked Context breakpoint. **Breakpoint exceptions** on page D2-1638 describes breakpoints.

Figure D2-2 on page D2-1642 shows an example of permitted watchpoint linking.

**D2.10.3 Execution conditions a watchpoint generates Watchpoint exceptions for**

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGWCR<\text{n}>_EL1.\{SSC, HMC, PAC\} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states. The comparison is made with the Security state of the PE, not the NS attribute of the physical instruction fetch address.

**Higher Mode Control, HMC, and Privileged Access Control, PAC**

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

**Note**

PAC controls which access privilege the watchpoint matches. This means that if the PE is executing an unprivileged load/store instruction at EL1, the data access might trigger a watchpoint that is programmed to match on EL0 accesses.
Table D2-15 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

Y or - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:

Y Can generate Watchpoint exceptions in that Exception level.

- Cannot generate Watchpoint exceptions in that Exception level.

Res Means that the combination of HMC, SSC, and PAC is reserved. See Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values on page D2-1665.

</table>

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Watchpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values on page D2-1665.

D2.10.4 Data address comparisons

An address comparison is successful if bits [48:2] of the current data address are equal to DBGWVR<n>_ELI[48:2], taking into account all of the following:

- The size of the access. See Size of the data access on page D2-1660.

If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in an AArch64 stage 1 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.

- The bytes selected by `DBGWVR<n>_EL1.BAS`. See Programming a watchpoint with eight bytes or fewer.
- Any address ranges indicated by `DBGWVR<n>_EL1.MASK`. See Programming a watchpoint with eight or more bytes on page D2-1662.

--- Note ---
- `DBGWVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits.
- `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored

### Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See Example D2-1.

**Example D2-1**

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.
2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by DC ZVA instructions is the DC ZVA block size that `DCZID_EL0.BS` defines. The size of data accesses initiated by DC IVAC instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that `CTR_EL0.DminLine` defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, Watchpoint behavior on accesses by cache maintenance instructions on page D2-1664.

### Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, `DBGWCR<n>_EL1.BAS`, selects which bytes in the doubleword starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint generates Watchpoint exceptions for.

If the address programmed into the `DBGWVR<n>_EL1` is:

- Doubleword-aligned:
  - All eight bits of `DBGWCR<n>_EL1.BAS` are used, and the descriptions given in Table D2-16 on page D2-1661 apply.
• Word-aligned but not doubleword-aligned:
  — Only \( \text{DBGWCR}<n>_\text{EL1}.\text{BAS}[3:0] \) are used, and the descriptions given in Table D2-17 apply. In this case, \( \text{DBGWCR}<n>_\text{EL1}.\text{BAS}[7:4] \) are RES0.

**Table D2-16 Supported BAS values when the DBGWVR_n_EL1 address alignment is doubleword**

<td>Generates a Watchpoint exception if byte at address ( \text{DBGWVR}&lt;n&gt;_\text{EL1}[48:2]:11 ) is accessed.</td>
</tr>
</tbody>
</table>

a. \( \text{DBGWCR}<n>_\text{EL1}.\text{BAS}[7:4] \) are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see *Other usage constraints* on page D2-1666.

When programming the BAS field with anything other than 0b11111111, a debugger must program \( \text{DBGWCR}<n>_\text{EL1}.\text{MASK} \) to be 0b000000. See *Programming dependencies of the BAS and MASK fields* on page D2-1665.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

• The access size is smaller or larger than the address region being watched.

• The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the \( \text{DBGWVR}<n>_\text{EL1}[48:3] \). See *Example D2-1* on page D2-1660.

The following are some example configurations of the BAS field:

• To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  — \( \text{DBGWVR}<n>_\text{EL1} \) with 0x1000.
  — \( \text{DBGWCR}<n>_\text{EL1}.\text{BAS} \) to be 0b00000000.
• To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  — DBGWVR<n>_EL1 with 0x2000.
  — DBGWCR<n>_EL1.BAS to be 0b00111000.

• If the address programmed into the DBGWVR<n>_EL1 is doubleword-aligned:
  — To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<n>_EL1.BAS to be 0b00001111.
  — To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<n>_EL1[31:3]:100 is accessed, program DBGWCR<n>_EL1.BAS to be 0b11110000.

—— Note ———
ARM deprecates programming a DBGWVR<n>_EL1 with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the MASK field, DBGWCR<n>_EL1.MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

• It is a size that is:
  — A power-of-two.
  — A minimum of eight bytes.
  — A maximum of 2GB.

• It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>0b00001</td>
<td>Reserved</td>
</tr>
<tr>
<td>0b00010</td>
<td>Reserved</td>
</tr>
<tr>
<td>0b00011</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>0b00100</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>0b00101</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>0b11111</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>

If n least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

• Address DBGWVR<n>_EL1[48:n]:000…
• Address DBGWVR<n>_EL1[48:n]:111…
• Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between DBGWVR<n>_EL1[48:4]:0000 and DBGWVR<n>_EL1[48:4]:1111, including these addresses.

—— Note ———
• The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
• For watchpoint behavior when its MASK field is programmed with a reserved value, see Reserved DBGWCR<n>_EL1.MASK values on page D2-1666.
When masking address bits, a debugger must both:

- Program `DBGWCR<n>_EL1.BAS` to be `0b11111111`. See `Programming dependencies of the BAS and MASK fields on page D2-1665`.

- In the `DBGWVR<n>_EL1`, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see `Other usage constraints on page D2-1666`.

### D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a `Fault Address Register` that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- `FAR_EL1`, if the exception is taken to EL1.
- `FAR_EL2`, if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the `EDWAR`.

For more information, see the subsections that follow. These are:

- `Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions`
- `Address recorded for Watchpoint exceptions generated by Data Cache instructions`

#### Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest `watchpointed address` accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.

- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than the `DC ZVA` block size.
  - Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

#### Example D2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte `0x8019`.

An A32 load multiple instruction then loads nine registers starting from address `0x8004` upwards. This triggers the watchpoint.

If the `DC ZVA` block size is:

- 32 bytes, the address that the PE records must be between `0x8004` and `0x8019` inclusive.
- 16 bytes, the address that the PE records must be between `0x8010` and `0x8019` inclusive.

#### Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.
D2.10.6  Watchpoint behavior on other instructions

The following never generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.

See also:

- Watchpoint behavior on accesses by Store-Exclusive instructions.
- Watchpoint behavior on accesses by cache maintenance instructions.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an exclusive monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by cache maintenance instructions

DC IVAC and DC ZVA operations are treated as data stores. This means that for a watchpoint to match on an access caused by one of these instructions, the debugger must program DBGWCR<n>_EL1.LSC to be one of the following:

- Match on data stores.
- Match on data stores and data loads.

No other data cache maintenance instructions can generate Watchpoint exceptions.

Note

For the size of data accesses performed by cache maintenance instructions, see Data address comparisons on page D2-1659. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.10.7  Usage constraints

See the following:

- Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values on page D2-1665.
- Reserved DBGWCR<n>_EL1.LBN values on page D2-1665.
- Programming dependencies of the BAS and MASK fields on page D2-1665.
- Reserved DBGWCR<n>_EL1.BAS values on page D2-1666.
- Reserved DBGWCR<n>_EL1.MASK values on page D2-1666.
- Other usage constraints on page D2-1666.
Reserved DBGWCR<n>_EL1.(HMC, SSC, PAC) values

Table D2-18 shows when particular combinations of DBGWCR<n>_EL1.(HMC, SSC, PAC) are reserved.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>All combinations where HMC or SSC is nonzero, and all combinations with PAC set to 0b00.</td>
<td>When both of EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>Combinations not included in Table D2-15 on page D2-1659.</td>
<td>Always</td>
</tr>
</tbody>
</table>

If an enabled watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct read of DBGWCR<n>_EL1.
- For a direct read of DBGWCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of HMC, SSC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of HMC, SSC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>_EL1.LBN values

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be 0b000000, so that the MASK field does not indicate any address ranges.

If the debugger uses both of these fields, behavior of the watchpoint is CONSTRAINED UNPREDICTABLE. Either:

- The watchpoint treats the MASK field as if it is programmed with 0b00000. In this case, the watchpoint is programmed with a single address and it generates Watchpoint exceptions for the bytes that the BAS field indicates.
- For each byte in the masked region, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception.
Reserved DBGWCR<n>_EL1.BAS values

If DBGWVR<n>_EL1[2] is 1, DBGWCR<n>_EL1.BAS[7:4] are RES0 and are ignored.

Reserved DBGWCR<n>_EL1.MASK values

If DBGWCR<n>_EL1.MASK is programmed with a reserved value, the watchpoint must behave as if it is either:

- Disabled.
- Programmed with an UNKNOWN value that is not reserved, that might be 0b00000.

Other usage constraints

For all watchpoints:

- DBGWVR<n>_EL1[1:0] are RES0 and are ignored.
- If DBGWCR<n>_EL1.BAS is programmed with non-contiguous bytes of memory, it is CONSTRAINED UNPREDICTABLE whether the Watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>_EL1.
- If DBGWCR<n>_EL1.MASK is nonzero, and any masked bits of DBGWVR<n>_EL1 are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>_EL1.LSC is 0b0.

For Unlinked watchpoints, DBGWCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked watchpoints:

- If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:
  - Disabled, and DBGWCR<n>_EL1.LBN for it reads UNKNOWN.
  - Links to an UNKNOWN context-aware breakpoint. In this case, it generates Watchpoint exceptions and DBGWCR<n>_EL1.LBN indicates which context-aware breakpoint it has linked to.
- If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

D2.10.8 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address on page D2-1667.

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

- Information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to.
- An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a Fault Address Register (FAR).

The ESR and FAR used is either:

- ESR_EL1 and FAR_EL1, if the exception is taken to EL1.
- ESR_EL2 and FAR_EL2, if the exception is taken to EL2.
Note

Watchpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-19 shows the recorded information.

Table D2-19 Information recorded in the ESR_ELx

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1 or ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>This is set to:</td>
</tr>
<tr>

<td>1 Write instruction.</td>
</tr>
<tr>
<td></td>
<td>ISS[5:0] Data Fault Status Code (DFSC). The PE sets this to the code for a debug exception, 0b100010.</td>
</tr>
</tbody>
</table>

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state

AArch64.WatchpointByteMatch() tests an individual byte accessed by an operation.

```c
// AArch64.WatchpointByteMatch()
// ========================================

boolean AArch64.WatchpointByteMatch(integer n, bits(64) waddress)
{
    top = AddrTop(waddress);
    bottom = if DBGWR_EL1[n]<2> == '1' then 2 else 3; // Word or doubleword
    byte_select_match = (DBGWCR_EL1[n].BAS<UInt(waddress<bottom-1:0>)> != '0');
    mask = UInt(DBGWCR_EL1[n].MASK);

    // If DBGWCR_EL1[n].MASK is non-zero value and DBGWCR_EL1[n].BAS is not set to '1111111', or
    // DBGWCR_EL1[n].BAS specifies a non-contiguous set of bytes behavior is CONSTRAINED
    // UNPREDICTABLE.
    if mask > 0 & !IsOnes(DBGWCR_EL1[n].BAS) then
        byte_select_match = ConstrainUnpredictableBool();
    else
        LSB = (DBGWCR_EL1[n].BAS AND NOT(DBGWCR_EL1[n].BAS - 1));
        MSB = (DBGWCR_EL1[n].BAS + LSB);
        if !IsZero(MSB AND (MSB - 1)) then // Not contiguous
```
byte_select_match = ConstrainUnpredictableBool();
bottom = 3;    // For the whole doubleword

// If the address mask is set to a reserved value, the behavior is CONSTRAINED UNPREDICTABLE.
if mask > 0 && mask <= 2 then
  (c, mask) = ConstrainUnpredictableInteger(3, 31);
  assert c IN {ConstraintDISABLED, ConstraintNONE, ConstraintUNKNOWN};
  case c of
    when ConstraintDISABLED return FALSE; // Disabled
    when ConstraintNONE mask = 0; // No masking
  // Otherwise the value returned by ConstrainUnpredictableInteger is a not-reserved value
endif

if mask > bottom then
  WVR_match = (vaddress<top:mask> == DBGWVR_EL1[n]<top:mask>);
  // If masked bits of DBGWVR_EL1[n] are not zero, the behavior is CONSTRAINED UNPREDICTABLE.
  if WVR_match && !IsZero(DBGWVR_EL1[n]<mask-1:bottom>) then
    WVR_match = ConstrainUnpredictableBool();
  else
    WVR_match = vaddress<top:bottom> == DBGWVR_EL1[n]<top:bottom>;
  endif
endif
return WVR_match && byte_select_match;

AArch64.StateMatch() tests the values in DBGWCR_EL1.<n>.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to. AArch64.StateMatch() is given in the Breakpoint exceptions section. See page D2-1652.

AArch64.WatchpointMatch() tests the value in DBGWVR_EL1.<n>.

// AArch64.WatchpointMatch()
// =========================
// Watchpoint matching in an AArch64 translation regime.

boolean AArch64.WatchpointMatch(integer n, bits(64) vaddress, integer size, boolean ispriv, boolean iswrite)
assert !ELUsingAArch32(S1TranslationRegime());
assert n <= UInt(ID_AA64DFR0_EL1.WRPs);

// "ispriv" is FALSE for LDTR/STTR instructions executed at EL1 and all
// load/stores at EL0, TRUE for all other load/stores. "iswrite" is TRUE for stores, FALSE for
// loads.
enabled = DBGWCR_EL1[n].E == '1';
linked = DBGWCR_EL1[n].WT == '1';

state_match = AArch64.StateMatch(DBGWCR_EL1[n].SSC, DBGWCR_EL1[n].HMC, DBGWCR_EL1[n].PAC,
linked, DBGWCR_EL1[n].LBN, ispriv);
ls_match = (DBGWCR_EL1[n].LSC<(if iswrite then 1 else 0)> == '1');

value_match = FALSE;
for byte = 0 to size - 1
  value_match = value_match || AArch64.WatchpointByteMatch(n, vaddress + byte);
return value_match && state_match && ls_match && enabled;

AArch64.CheckWatchpoint() generates a FaultRecord that AArch64.Abort raises a Watchpoint exception for if all of the following are true:

• MDSCR_EL1.MDE is 1.

• Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state on page D2-1629.

• All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions on page D2-1656.
Note

AArch64.CheckWatchpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

// AArch64.CheckWatchpoint()
// =========================
// Called before accessing the memory location of "size" bytes at "address".

FaultRecord AArch64.CheckWatchpoint(bits(64) vaddress, AccType acctype, boolean iswrite, integer size)
assert !ELUsingAArch32(S1TranslationRegime());

match = FALSE;
ispriv = PSTATE.EL != EL0 && !(PSTATE.EL == EL1 && acctype == AccType_UNPRIV);

for i = 0 to UInt(ID_AA64DFR0_EL1.WRPs)
    match = match || AArch64.WatchpointMatch(i, vaddress, size, ispriv, iswrite);

if match && HaltOnBreakpointOrWatchpoint() then
    reason = DebugHalt_Watchpoint;
    Halt(reason);
elsif match && MDSCR_EL1.MDE == '1' && AArch64.GenerateDebugExceptions() then
    return AArch64.DebugFault(acctype, iswrite);
else
    return AArch64.NoFault();

AArch64.WatchpointException() is called to generate a Watchpoint exception.

// AArch64.WatchpointException()
// =============================

AArch64.WatchpointException(bits(64) vaddress, FaultRecord fault)
assert PSTATE.EL != EL3;

route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
(HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;

exception = AArch64.AbortSyndrome(Exception_Watchpoint, fault, vaddress);

if PSTATE.EL == EL2 || route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 stage 1 translation regimes.

--- Note ---
This means that they are never taken to EL1 using AArch64 and are only supported if at least EL1 using AArch32 is supported.

---

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See Routing debug exceptions on page D2-1627.

AArch64.VectorCatchException() is called to generate a Vector Catch exception:

```c
// AArch64.VectorCatchException()
// =================================
// Vector Catch taken from EL0 or EL1 to EL2. This can only be called when debug exceptions are being routed to EL2, as Vector Catch is a legacy debug event.
AArch64.VectorCatchException(FaultRecord fault)
    assert PSTATE.EL != EL2;
    assert HaveEL(EL2) && !IsSecure() && (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1');

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;
    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_VectorCatch, fault, vaddress);

    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
```

Vector Catch exceptions on page G2-4009 describes Vector Catch exceptions.
D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

- About Software Step exceptions.
- Rules for setting MDSCR_EL1.SS to 1.
- The software step state machine on page D2-1672.
- Entering the active-not-pending state on page D2-1674.
- Behavior in the active-not-pending state on page D2-1678.
- Entering the active-pending state on page D2-1679.
- Behavior in the active-pending state on page D2-1680.
- Stepping T32 IT instructions on page D2-1680.
- Exception syndrome information and preferred return address on page D2-1681.
- Additional considerations on page D2-1682.
- Pseudocode description of Software Step exceptions on page D2-1684.

D2.12.1 About Software Step exceptions

Software step is an ARMv8-A resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   a. Enables software step by setting MDSCR_EL1.SS to 1. See The debug exception enable controls on page D2-1626.
   b. Executes an exception return instruction, ERET, to branch to the instruction to be single-stepped in the software being debugged.

2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state on page D2-1629.

A state machine describes the behavior of software step, shown in The software step state machine on page D2-1672.

--- Note ---

In the remainder of this Software Step exceptions section, including in all subsections, EL_D is used to mean the Exception level that Software Step exceptions are targeting. Routing debug exceptions on page D2-1627 defines EL_D as the debug target Exception level.

D2.12.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

The Exception level that hosts the debugger software must be using AArch64.
D2.12.3 The software step state machine

In Figure D2-4 on page D2-1673:
- The OS Lock is unlocked and EDPRSR.DLK is 0.
- The PE is not in Secure state with MDCR_EL3.SDD set to 1. That is, the PE is in Non-secure state, or is in Secure state with MDCR_EL3.SDD set to 0, or the implementation does not include EL3.
Figure D2-4 Software step state machine

Execution is at either:
- An Exception level that is higher than EL0.
- EL0 with \( \text{PSTATE.}D = 1 \) \& \( \text{MDSCR EL1.KDE} = 0 \).
This is termed execution in a debugger or above.

To make the PE single-step an instruction, the debugger:
1. Sets SPSR_ELx.SS to 1.
2. Programs the ELR_ELx to point to the instruction to be stepped.
3. Executes an ERET instruction.

Execution is in the software being debugged, at either:
- An Exception level that is lower than EL0.
- EL0 with \( \text{PSTATE.}D = 0 \) \& \( \text{MDSCR EL1.KDE} = 1 \).

A Software Step exception is pending.

Execution has returned to the debugger.

---

a. The step is the PE either:
- Taking an exception to an Exception level that debug exceptions are disabled from.
- If execution is at EL0 with \( \text{MDSCR EL1.KDE} = 1 \), executing an instruction that sets PSTATE.D to 1.
Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from EL0 when PSTATE.D is 1.

b. The step is the PE either:
- Executing the instruction to be stepped without taking an exception.
- Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at EL0 with \( \text{MDSCR EL1.KDE} = 1 \), by software setting PSTATE.D to 0.

---

To make an asynchronous exception taken to an Exception level that debug exceptions are disabled from:

To make the PE single-step an instruction, the debugger:
1. Sets SPSR_ELx.SS to 1.
2. Programs the ELR_ELx to point to the instruction to be stepped.
3. Executes an ERET instruction.
For a description of when debug exceptions are enabled or disabled from an Exception level, see *Enabling debug exceptions from the current Exception level and Security state* on page D2-1629.

For more information about how a step is completed, see *Behavior in the active-not-pending state* on page D2-1678.

The software step states are:

**Inactive**

Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- MDSCR_EL1.SS is 0.
- EL_D is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

**Active-not-pending**

None of the conditions mentioned in *Inactive* are true, therefore software step is active.

The current instruction is the instruction to be stepped.

**Active-pending**

None of the conditions mentioned in *Inactive* are true, therefore software step is active.

A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not pending state or the active-pending state depends on PSTATE.SS. Table D2-20 shows this.

**Table D2-20 State machine states**

<table>
<thead>
<tr>
<th>MDSCR_EL1.SS</th>

</tr>
<tr>
<td>1</td>
<td>AArch64</td>
<td>Enabled</td>
<td>0</td>
<td>Active-pending</td>
</tr>
</tbody>
</table>

**D2.12.4 Entering the active-not-pending state**

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an ERET instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.
- Might enter the active-not-pending state on exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 1. See *Exiting Debug state* on page H2-5014.

An ERET instruction only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:

- MDSCR_EL1.SS is 1.
- EL_D is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the ERET instruction targets.

Otherwise, ERET instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS.
Table D2-21 shows this. In the table:

**Lock**
- Means the value of (OSLSR_EL1.OSLK OR EDPRSR.DLK).

**NS**
- Is SCR_EL3.NS.

**SDD**
- Is MDCR_EL3.SDD. See *Disabling debug exceptions from Secure state* on page D2-1630.

**TDE**
- Is MDCR_EL2.TDE. See *Routing debug exceptions* on page D2-1627.

For:

- SCR_EL3.NS == 0 or MDCR_EL2.TDE == 0, and EL1 using AArch64, so that ELD is EL1 using AArch64, Table D2-22 on page D2-1676 shows the value an ERET writes to PSTATE.SS.

- SCR_EL3.NS == 1 and MDCR_EL2.TDE == 1 and EL2 using AArch64, so that ELD is EL2 using AArch64, Table D2-23 on page D2-1677 shows the value an ERET writes to PSTATE.SS.

In both tables:

**From EL**
- Means the Exception level that the PE executes the ERET at.

**Target EL**
- Is the target Exception level of the ERET.

--- **Note** ---

If the ERET is an illegal exception return, the target Exception level of the ERET is the current Exception level. See *Illegal return events from AArch64 state* on page D1-1534.

a. Because **MDSCR_EL1.SS** == 1, it means that the **ERET** is itself being stepped.
b. Depends on **SPSR_EL2.D**.

--- **Note** ---

No AArch32 instruction can set **PSTATE.SS** to 1.
D2.12.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
- Enters Debug state because of a Halting debug event.

If the PE executes the instruction to be stepped without taking any exceptions:
- After it has executed the instruction, it sets PSTATE.SS to 0 and software step advances to the active-pending state. See Behavior in the active-pending state on page D2-1680.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- If the PE takes an exception to an Exception level that is using AArch64.
- If the PE takes an exception to an Exception level that is using AArch32 on page D2-1679.

If the PE enters Debug state because of a Halting debug event, behavior is as described in Entering Debug state and Software Step on page H2-4986.

If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets SPSR_ELx.SS to 0 or 1, depending on the exception. See Table D2-24.
- Sets PSTATE.SS to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
  - Enabled Software step enters the active-pending state.
  - Disabled Software step enters the inactive state.
  In either case, on taking the exception, a step is complete.
- Sets PSTATE.D to 1.

<table>
<thead>
<tr>
<th>Exception description</th>
<th>Exceptions</th>
<th>SPSR_ELx.SS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.</td>
<td>Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.</td>
<td>0</td>
</tr>
<tr>
<td>Exceptions whose preferred return address is the address of the instruction to be stepped.</td>
<td>All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.</td>
<td>1</td>
</tr>
</tbody>
</table>

Note

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because HCR_EL2.TSC is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so SPSR_ELx.SS is set to 1, not 0.
If the PE takes an exception to an Exception level that is using AArch32

This can only happen when all of the following is true:

• EL2 is implemented and is using AArch64, the PE is executing in Non-secure state, and MDCR_EL2.TDE is 1. Because MDCR_EL2.TDE is 1, EL_D is EL2.
• The exception is taken to Non-secure EL1 using AArch32.

As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

___Note___

• Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because EL_D is EL2, and debug exceptions are always enabled from Exception levels that are lower than EL_D.
• AArch32 SPSRs have no SS bit. Where an SPSR_ELx register architecturally maps to an AArch32 SPSR_<mode> register, SPSR_ELx.SS maps to SPSR_<mode>[21].

SPSR_<mode>[21] is always RES0. The PE always sets SPSR_<mode>[21] to 0 on taking an exception to an Exception level that is using AArch32.

a. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-4 on page D2-1673.

b. SPSR_<mode>[21] is RES0.

D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

• MDSCR_EL1.SS is 1.
• Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

• Executing the instruction to be stepped without taking any exceptions.
• Taking an exception.
Note

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to Non-secure EL1 when MDCR_EL2.TDE is 1. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

While software step is in the inactive state

The PE either:

• Executing an ERET instruction when SPSR_ELx.SS is 0.
• If MDSCR_EL1.KDE is 1, executing an MSR DAIF or MSR DAIFClr instruction that clears PSTATE.D to 0.

In addition, software step might enter the active-pending state either:

• After a direct write to a system register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine on page D2-1684.
• On exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 0. See Exiting Debug state on page H2-5014.

D2.12.7 Behavior in the active-pending state

In this state, a Software Step exception is pending, and the PE takes it on the current instruction.

Software Step exceptions have priority over all other exceptions except asynchronous exceptions taken to an Exception level or Security state that debug exceptions are disabled from.

This means that there are some asynchronous exceptions that Software Step exceptions have priority over.

Note

• This is the only case where a synchronous exception explicitly has a higher priority than asynchronous exceptions.

• For a description of when debug exceptions are enabled or disabled from an Exception level or Security state, see Enabling debug exceptions from the current Exception level and Security state on page D2-1629.

In cases where both a Software Step exception is pending and an asynchronous exception taken to an Exception level or Security state that debug exceptions are disabled from is pending, the architecture does not define which exception is taken first.

D2.12.8 Stepping T32 IT instructions

The ARMv8-A architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

• The PE considers this combination to be one instruction.
• The PE considers this combination to be two instructions.

It is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable IT Disable bit, ITD. For example:

• The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD bit.
• The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD bit.
• The PE might consider this combination to be one instruction when the applicable ITD bit is 1, and two instructions when it is 0.
The applicable ITD bit is either:
- `SCTLR_EL1.ITD` if execution is in EL0 using AArch32 when EL1 is using AArch64.
- `SCTLR.ITD` if execution is in EL1 using AArch32 when EL2 is using AArch64.

## D2.12.9 Exception syndrome information and preferred return address

See the following:
- *Exception syndrome information*.
- *Preferred return address* on page D2-1682.

### Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:
- `ESR_EL1`.
- `ESR_EL2`.

--- Note ---

Software Step Exceptions cannot be taken to EL3.

Table D2-26 shows the information that the PE records.

**Table D2-26 Information recorded in the ESR_ELx**

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1 or ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Exception Class</strong>, EC</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td><strong>Instruction Length</strong>, IL</td>
<td>The PE sets this to 1.</td>
</tr>
<tr>
<td><strong>Instruction Specific Syndrome</strong>, ISS</td>
<td><em>Instruction Syndrome Valid</em> (ISV). This indicates whether the EX bit, ISS[6], is valid. The PE sets this to:</td>
</tr>
<tr>
<td>ISS[24]</td>
<td>0 Not valid.</td>
</tr>
<tr>
<td>ISS[6]</td>
<td>Exclusive operation (EX). The PE sets this to indicate whether the instruction stepped was a Load-Exclusive class of instruction:</td>
</tr>
<tr>
<td>0</td>
<td>The stepped instruction was not a Load-Exclusive instruction.</td>
</tr>
<tr>
<td>1</td>
<td>The stepped instruction was a Load-Exclusive instruction.</td>
</tr>
<tr>
<td>ISS[5:0]</td>
<td>Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.</td>
</tr>
</tbody>
</table>

The PE only sets ISV to 1 if an instruction was stepped. If the PE sets ISV to 1, it must also set EX to indicate whether the instruction stepped was a Load-Exclusive class of instruction.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, the PE sets both `ESR_ELx.[ISV, EX]` to 0.

--- Note ---

An implementation that always sets ISV to 0 and never sets EX is not compliant.
ESR_ELx.ISV is **UNKNOWN** if, in the active-not-pending state, either:

- The instruction stepped was an **ERET** or an **ISB**. In these cases, ESR_ELx.EX is set to 0.
- **MDCR_EL2.TDE** was set to 1 and either:
  - The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1. In this case, the instruction to be stepped never completed.
  - The PE took an asynchronous exception before it could execute the instruction to be stepped. In this case, the instruction to be stepped was never executed.

In both of these cases, ESR_ELx.EX is set to the correct value for the instruction.

<table>
<thead>
<tr>
<th>Table D2-27 Values that the PE can record in ESR_ELx.{ISV, EX}</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1.</td>
</tr>
<tr>
<td>The PE took an asynchronous exception before it could execute the instruction to be stepped.</td>
</tr>
</tbody>
</table>

---

**Note**

- A Load-Exclusive class of instruction is any one of the following:
  - In the A64 instruction set, any instruction that has a mnemonic starting with either **LDX** or **LDAX**.
  - In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either **LDREX** or **LDAEX**.
- ESR_ELx.EX is **UNKNOWN** if the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test.

---

**Preferred return address**

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

**D2.12.10 Additional considerations**

This section contains the following:

- *Behavior when an ERET instruction is an illegal exception return* on page D2-1683.
- *Behavior when the instruction stepped writes a misaligned PC value* on page D2-1683.
- *Stepping code that uses exclusive monitors* on page D2-1683.
- *Synchronization and the software step state machine* on page D2-1684.
Behavior when an ERET instruction is an illegal exception return

If the conditions for entering the active-not-pending state in *Entering the active-not-pending state on page D2-1674* are met, but the PE executes an ERET instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the ERET, software step can advance from the inactive state to one of the active states. Consider the following case:

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.

   PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.

2. The PE executes an ERET instruction.

3. The intended target of the ERET is EL2. This means that the ERET is an illegal exception return because the intended target is higher than the Exception level the ERET it is executed at. In this case, the ERET must target EL1 instead of EL2.

   If SPSR_EL1.D is 0, then on the ERET PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

- If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.
  
  In this case, an Illegal Execution State exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution State exception instead of executing the instruction to be stepped.

- If SPSR_ELx.SS is 0, software step advances to the active-pending state.
  
  In this case, a Software Step exception and an Illegal Execution State exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

---

**Note**

Synchronous exception prioritization on page D1-1546 shows the relative priorities of synchronous exceptions.

Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a Misaligned PC exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

**AArch64**

A Misaligned PC exception is generated.

**AArch32**

The return from the Software Step exception forces the PC to the correct alignment, and no Misaligned PC exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a Misaligned PC exception.

Stepping code that uses exclusive monitors

The ARMv8-A architecture provides no mechanism for preserving the state of the exclusive monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive class of instruction.
Debugger software can use this to detect the state of the exclusive monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive class of instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all exclusive monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see Exception syndrome information and preferred return address on page D2-1681.

### Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a system register.
- A write to an external debug register that affects the routing of debug exceptions.

Because the software step state machine indirectly reads these registers, it is not guaranteed to observe any new values until after a Context Synchronization Operation (CSO) has occurred.

In the time between a write to one of these registers and the next CSO, it is constrained unpredictable whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a CSO, the state machine must use the state of the PE after the write.

---

**Example D2-3**

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A CSO occurs.

During step 2, it is constrained unpredictable whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:

- Inactive state, then after the CSO, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the CSO.

---

### Pseudocode description of Software Step exceptions

SSAdvance() advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

```pseudocode
// SSAdvance()
// ===========
// Advance the Software Step state machine.

SSAdvance()
```

```pseudocode
// A simpler implementation of this function just clears PSTATE.SS to zero regardless of the // current Software Step state machine. However, this check is made to illustrate that the // processor only needs to consider advancing the state machine from the active-not-pending // state.

target = DebugTarget();
step_enabled = !ELUsingAArch32(target) && MDSCR_EL1.SS == '1';
active_not_pending = step_enabled && PSTATE.SS == '1';

if active_not_pending then PSTATE.SS = '0';
return;
```

CheckSoftwareStep() checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.
// CheckSoftwareStep()
// ===================
// Take a Software Step exception if in the active-pending state

CheckSoftwareStep()

// Other self-hosted debug functions will call AArch32.GenerateDebugExceptions() if called from
// AArch32 state. However, because Software Step is only active when the debug target Exception
// level is using AArch64, CheckSoftwareStep only calls AArch64.GenerateDebugExceptions().
if !ELUsingAArch32(DebugTarget()) && AArch64.GenerateDebugExceptions() then
  if MDSCR_EL1.SS == '1' && PSTATE.SS == '0' then AArch64.SoftwareStepException;

DebugExceptionReturnSS() returns the value to write to PSTATE.SS on an exception return or an exit from Debug
state. See Entering the active-not-pending state on page D2-1674.

// DebugExceptionReturnSS()
// =======================================
// Returns value to write to PSTATE.SS on an exception return or Debug state exit.

bit DebugExceptionReturnSS(bits(32) spsr)
  assert Halted() || Restarting() || PSTATE.EL != EL0;

  SS_bit = '0';

  if MDSCR_EL1.SS == '1' then
    if Restarting() then
      enabled_at_source = FALSE;
    elsif UsingAArch32() then
      enabled_at_source = AArch32.GenerateDebugExceptions();
    else
      enabled_at_source = AArch64.GenerateDebugExceptions();
    fi
  fi

  if IllegalExceptionReturn(spsr) then
    dest = PSTATE.EL;
  else
    (valid, dest) = ELFromSPSR(spsr);  assert valid;
  fi

  secure = IsSecureBelowEL3() || dest == EL3;

  if ELUsingAArch32(dest) then
    enabled_at_dest = AArch32.GenerateDebugExceptionsFrom(dest, secure);
  else
    mask = spsr<9>;
    enabled_at_dest = AArch64.GenerateDebugExceptionsFrom(dest, secure, mask);
  fi

  ELd = DebugTargetFrom(secure);
  if !ELUsingAArch32(ELd) && !enabled_at_source && enabled_at_dest then
    SS_bit = spsr<21>;  
  fi

  return SS_bit;
The behavior of debug depends on all of the following:

• The state of the external debug authentication interface.
• Indirect reads of:
  — External debug registers.
  — System registers, including system debug registers.
  — Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context Synchronization Operation (CSO) has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a CSO has occurred.

For any instructions executed between the time when the change is made and the time when the next CSO occurs, it is **CONSTRAINED UNPREDICTABLE** whether debug uses the state of the PE before the change, or the state of the PE after the change.

**Example D2-4**

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A CSO occurs.

In this case, it is **CONSTRAINED UNPREDICTABLE** whether the instruction generates a Breakpoint exception.

**Example D2-5**

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A CSO occurs.

During the time when the PE is executing some instructions, step 2, it is **CONSTRAINED UNPREDICTABLE** whether debug exceptions other than Software Breakpoint Instruction exceptions can be generated.

**Note**

• Some register updates are self synchronizing. Others require an explicit CSO. For more information, see both:
  — Synchronization requirements for System registers on page D7-1902.
  — Synchronization of changes to the external debug registers on page H8-5102.
• See Context synchronization operation for the definition of this term.
Chapter D3
The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture* on page D3-1688.
- *Address space* on page D3-1689.
- *Mixed-endian support* on page D3-1690.
- *Cache support* on page D3-1691.
- *External aborts* on page D3-1711.
- *Memory barrier instructions* on page D3-1713.
- *Pseudocode description of general memory system instructions* on page D3-1714.
D3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page B2-72.

D3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a Virtual Memory System Architecture (VMSA), described in Chapter D4 The AArch64 Virtual Memory System Architecture.

D3.1.2 Memory attributes

Memory types and attributes on page B2-93 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table D3-1 shows the memory attributes that are visible at the system level.

<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

Table D3-1 Memory attribute summary
D3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see Address size configuration on page D4-1733.

D3.2.1 Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

(address_of_current_instruction) + (size_of_executed_instruction)

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows 0xFFFF FFFF FFFF FFFF, the program counter becomes UNKNOWN.

Note
Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the 0xFFFF_FFFF_FFFF_FFFF boundary when tagged addresses are not used, or the 0xFFF_FFFF_FFFF_FFFF boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.
D3.3 Mixed-endian support

A control bit, SCTLR_EL1.E0E is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. Table D3-2 shows the endianness of explicit data accesses and translation table walks.

Table D3-2 Endianness support

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Explicit data accesses</th>
<th>Stage 1 translation table walks</th>
<th>Stage 2 translation table walks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>SCTLR_EL1.E0E</td>
<td>SCTLR_EL1.EE</td>
<td>SCTLR_EL2.EE</td>
</tr>
<tr>
<td>EL1</td>
<td>SCTLR_EL1.EE</td>
<td>SCTLR_EL1.EE</td>
<td>SCTLR_EL2.EE</td>
</tr>
<tr>
<td>EL2</td>
<td>SCTLR_EL2.EE</td>
<td>SCTLR_EL2.EE</td>
<td>N/A</td>
</tr>
<tr>
<td>EL3</td>
<td>SCTLR_EL3.EE</td>
<td>SCTLR_EL3.EE</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Note**

SCTLR_EL1.E0E has no effect on the endianness of the LDTR, LDTRH, LDTRSH, and LDTRSW instructions, or on the endianness of the STTR and STTRH instructions, when these are executed at EL1.

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR_ELx.EE is R/W and SCTLR_EL1.E0E is R/W.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR_ELx is RES0 and SCTLR_EL1.E0E is R/W.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR_ELx is RES1 and SCTLR_EL1.E0E is R/W.
- All Exception levels support only little-endianness:
  - SCTLR_ELx is RES0 and SCTLR_EL1.E0E is RES0.
- All Exception levels support only big-endianness:
  - SCTLR_ELx is RES1 and SCTLR_EL1.E0E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1. PSTATE.E is ignored in AArch64 state.

The `BigEndian()` function determines whether the current Exception level and Execution state is using big-endian data:

```c
// BigEndian()
// ===========

boolean BigEndian()
{ // boolean bigend;
    if UsingAArch32() then
        bigend = (PSTATE.E != '0');
    elsif PSTATE.EL == EL0 then
        bigend = (SCTLR_EL1.E0E != '0');
    else
        bigend = (SCTLR[.].EE != '0');
    return bigend;
}
```
D3.4 Cache support

This section describes the ARMv8 cache identification and control mechanisms, and the cache maintenance instructions, in the following sections:

- General behavior of the caches
- Cache identification on page D3-1692.
- Cacheability, cache allocation hints, and cache transient hints on page D3-1693.
- Behavior of caches at reset on page D3-1693
- Cache enabling and disabling on page D3-1694.
- Non-cacheable accesses and instruction caches on page D3-1696.
- Overview of the cache maintenance instructions on page D3-1696.
- Cache maintenance instructions on page D3-1700
- Data cache zero instruction on page D3-1708.
- Cache lockdown on page D3-1708.
- System level caches on page D3-1710.
- Branch prediction on page D3-1710.

See also Caches in a VMSA implementation on page D4-1842.

D3.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see The interaction of cache lockdown with cache maintenance instructions on page D3-1709.

- If a memory location is marked as cacheable for the translation regime at either the current Exception level or at a higher Exception level, then there is no mechanism that can guarantee that the memory location cannot be allocated to an enabled cache at any time.
Any application must assume that any memory location with such access permissions and cacheability attributes can be allocated to any enabled cache at any time.

- It is guaranteed that no memory location that does not have a Cacheable attribute is allocated into the cache.
- It is guaranteed that no memory location is allocated to the cache if it is not marked as cacheable in both:
  - The translation regime at the current Exception level.
  - The translation regime at a higher Exception level.
- For data accesses, any memory location that is marked as Normal Inner Shareable or Normal Outer Shareable is guaranteed to be coherent with all masters in its shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR_EL0 identifies the Cache Write-back Granule.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to its size.

In the following situations it is UNPREDICTABLE whether the location is returned from cache or from memory:

- The location is not marked as Cacheable but is contained in the cache. This situation can occur if a location is marked as Non-cacheable after it has been allocated into the cache.
- The location is marked as Cacheable and might be contained in the cache, but the cache is disabled.

### D3.4.2 Cache identification

The ARMv8 cache identification registers describe the implemented caches that are under the control of the PE:

- The Cache Type Register, CTR_EL0, defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  - The cache indexing and tagging policy of the level 1 instruction cache.

- A single Cache Level ID Register defines:
  - The type of cache implemented at each cache level, up to the maximum of seven levels.
  - The Level of Coherence (LoC) for the caches. See Terms used in describing the maintenance instructions on page D3-1696 for a definition of these terms.
  - The Level of Unification Uniprocessor (LoUU) for the caches. See Terms used in describing the maintenance instructions on page D3-1696 for a definition of these terms.
  - An optional ISB field to indicate the cacheable boundary between inner and outer domains.

For more information, see CLIDR_EL1, Cache Level ID Register on page D7-1923.

- A single Cache Size Selection Register selects the cache level and cache type of the current Cache Size Identification Register, see CSSELR_EL1, Cache Size Selection Register on page D7-1933.

- For each implemented cache, across all the levels of caching, a Cache Size Identification Register defines:
  - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  - The number of sets, associativity and line length of the cache. See Terms used in describing the maintenance instructions on page D3-1696 for a definition of these terms.

For more information, see CCSIDR_EL1, Current Cache Size ID Register on page D7-1921.
To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
   - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     - An instruction cache.
     - A data or unified cache.
   - Read the Cache Size ID Register to find details of the cache.

### D3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations.

As described in Memory types and attributes on page B2-93, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. A cache transient hint provides a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future.

The following cache allocation hints can be used in ARMv8:

- Read-Allocate, Transient Read-Allocate, or No Read-Allocate.
- Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

**Note**

A Cacheable location with both no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, no Read-Allocate, no Write-Allocate.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

### D3.4.4 Behavior of caches at reset

In ARMv8:

- All caches are disabled at reset.
- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the cache is disabled the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
In particular, if an implementation permits cache hits when the cache is disabled and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

When it is enabled, the state of a cache is UNPREDICTABLE if the appropriate initialization routine has not been performed.

### D3.4.5 Cache enabling and disabling

When a data cache or unified cache is disabled for a translation regime, data accesses and translation table walks from that translation regime to all Normal memory types behave as Non-cacheable for all levels of data caches and unified caches.

For the EL1&0 translation regime:

- When SCTLR_EL1.C == 0, this makes all stage 1 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 1 translation tables Non-cacheable.

- When HCR_EL2.CD == 1, this makes all stage 2 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 2 translation tables Non-cacheable.

--- **Note** ---

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D4-1814.
- The SCTLR_EL1.C bit has no effect on the EL2 and EL3 translation regimes.
- The HCR_EL2.CD bit affects only stage 2 of the Non-secure EL1&0 translation regime.

- When HCR_EL2.DC == 1, this makes all stage 1 translations for data accesses and all accesses to the EL1&0 stage 1 translation tables Normal Non-shareable Inner Write-Back Cacheable Read Allocate Write Allocate, Outer Write-Back Cacheable Read Allocate Write Allocate.

For the EL2 translation regime:

- When SCTLR_EL2.C == 0, all data accesses to Normal memory using the EL2 translation regime are Non-cacheable. This means all accesses made by the EL2 translation table walks are Non-cacheable.

--- **Note** ---

The SCTLR_EL2.C bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When SCTLR_EL3.C == 0, all data accesses to Normal memory using the EL3 translation regime are Non-cacheable. It also makes all accesses made by the EL3 translation table walks are Non-cacheable.

--- **Note** ---

The SCTLR_EL3.C bit has no effect on the EL1&0 and EL2 translation regimes.

The effect of SCTLR_ELx.C, HCR_EL2.DC and HCR_EL2.CD is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.

When an instruction cache is disabled for a translation regime, instruction accesses from that translation regime to all Normal memory types behave as Non-cacheable for all levels of instruction caches and unified caches.
For the EL1&0 translation regime:

- When SCTLR_EL1.I == 0, this makes all stage 1 translations for instruction accesses to Normal memory Non-cacheable.
- When HCR_EL2.ID == 1, this makes all stage 2 translations for instruction accesses to Normal memory Non-cacheable.

--- Note
---
- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-1814.
- The SCTLR_EL1.I bit has no effect on the EL2 and EL3 translation regimes.
- The HCR_EL2.ID bit affects only stage 2 of the Non-secure EL1&0 translation regime.

---

- If HCR_EL2.DC == 1, then the Non-secure stage 1 EL1&0 translation regime is cacheable regardless of the value of SCTLR_EL1.I.

For the EL2 translation regime:

- When SCTLR_EL2.I == 0, all instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

--- Note
---
The SCTLR_EL2.I bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When SCTLR_EL3.I == 0, all instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

--- Note
---
The SCTLR_EL3.I bit has no effect on the EL1&0 and EL2 translation regimes.

In addition, when SCTLR_ELx.M == 0, indicating that the stage 1 translations are disabled for that translation regime, the SCTLR_ELx.I bit has the following effect:

- If SCTLR_ELx.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If SCTLR_ELx.I == 1, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

When the MMU is off, all instruction accesses are to Normal memory and:

- If SCTLR_ELx.I == 0, the behavior is Normal Non-cacheable.
- If SCTLR_ELx.I == 1, the behavior is Normal Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

For the Non-secure EL1 translation regime, when the MMU is off and SCTLR_EL1.M == 0 and HCR_EL2.DC == 0, all instruction accesses are to Normal memory and:

- If SCTLR_ELx.I == 0, the behavior is Normal Non-cacheable.
- If SCTLR_ELx.I == 1, the behavior is Normal Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

--- Note
---
- In conjunction with the requirements in Non-cacheable accesses and instruction caches on page D3-1696, this means that the architecturally required effect of SCTLR_ELx.I is limited to its effect on caching instruction accesses in unified caches.
D3 The AArch64 System Level Memory Model
D3.4 Cache support

- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in Mismatched memory attributes on page B2-104 must be followed to manage the corresponding loss of coherency.

D3.4.6 Non-cacheable accesses and instruction caches

Instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where the instruction cache is disabled.

Therefore when using self-modified code in non-cacheable space in a uniprocessor system, the following sequence is required:

; Enter this code with <Wt> containing the new 32-bit instruction to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn] ; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;

In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence, but additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences.

Larger blocks of instructions can be modified using the IC IALLU instruction for a uniprocessor system, or a IC IALLUIS for a multiprocessor system.

Note

This section applies even when the instruction cache is disabled in AArch64, as described in Cache enabling and disabling on page D3-1694.

D3.4.7 Overview of the cache maintenance instructions

The following sections give general information about cache maintenance:

- Terms used in describing the maintenance instructions.
- The ARMv8 abstraction of the cache hierarchy on page D3-1699.

The following sections describe cache maintenance instruction:

- Instruction cache maintenance instructions (IC*) on page D3-1701.
- Data cache maintenance instructions (DC*) on page D3-1701.

Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- Terminology for cache maintenance instruction operating by virtual address, VA on page D3-1697.
- Terminology for cache maintenance instructions operating by set/way on page D3-1697.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D3-1698.
Terminology for cache maintenance instruction operating by virtual address, VA

The addresses used by the PE are VAs. When all applicable stages of translation are disabled, the virtual address is identical to the physical address.

Note
For more information about memory system behavior when MMUs are disabled, see The effects of disabling a stage of address translation on page D4-1761.

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:
• For an instruction executed at EL1, the current system Address Space Identifier, ASID.
• The current Security state.
• Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
• For an instruction executed from a Non-secure EL1 state, the Virtual Machine Identifier, VMID.

For a data or unified cache maintenance instruction by VA, the operation cannot generate a Data Abort exception for a Permission fault, except for the Permission fault cases described in:
• Data cache maintenance instructions (DC*) on page D3-1701.
• Stage 2 fault on a stage 1 translation table walk on page D4-1822.

For an instruction cache maintenance instruction by VA:
• It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
• The operation cannot generate a Data Abort exception for a Permission fault, except for the Permission fault case described in Stage 2 fault on a stage 1 translation table walk on page D4-1822.

For more information about these faults, see MMU faults on page D4-1816.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level
The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID register. See CLIDR_EL1, Cache Level ID Register on page D7-1923.
In the ARM architecture, the lower numbered levels are those closest to the PE. See Memory hierarchy on page B2-72.

Set
Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.
In the ARM architecture, sets are numbered from 0.

Way
The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.
In the ARM architecture, ways are numbered from 0.

Note
Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.
Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.

The Clean and Invalidate instructions address these two issues. The definitions of these instructions are:

**Clean**
A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

**Invalidate**
A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates does not have a Normal Cacheable attribute, or if the cache is disabled, then an invalidate instruction also ensures that this address is not present in the cache.

--- Note ---
Entries for addresses with a Normal Cacheable attribute can be allocated to an enabled cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in an enabled cache.

---

**Clean and Invalidate**

A cache clean and invalidate instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.

- For instruction operating by VA, two conceptual points are defined:

  **Point of Coherency (PoC)**
  For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

  --- Note ---
  The presence of system caches can affect the definition of point of coherency as described in *System level caches on page D3-1710.*

---

---
Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the CLIDR_EL1 relate to these conceptual points:

**LoC, Level of Coherence**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

**LoUU, Level of Unification, uniprocessor**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**LoUIS, Level of Unification, Inner Shareable**

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see *CLIDR_EL1, Cache Level ID Register on page D7-1923.*

**The ARMv8 abstraction of the cache hierarchy**

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- *Cache maintenance instructions that operate by address on page D3-1700.*
- *Cache maintenance instructions that operate by set/way on page D3-1700.*
Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See Terms used in describing the maintenance instructions on page D3-1696 for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

Cache maintenance instructions lists the address-based maintenance instructions.

The CTR_EL0 holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

Cache maintenance instructions lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

D3.4.8 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 system instruction class in the register encoding space. For encoding details and other general information on these system instruction, see System instructions on page C3-138, SYS on page C6-778 and Cache maintenance instructions, and data cache zero on page C5-250.

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. Table D3-3 shows these system instructions. Instructions that take an argument include Xt in the instruction description.

--- Note ---

In Table D3-3 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.

Table D3-3 System instructions for cache maintenance
Instruction cache maintenance instructions (IC*)

The A64 assembly syntax for these instructions is described in System instructions on page C3-138.

Where an address argument for these instructions is required, it takes the form of a 64-bit register that holds the virtual address argument. No restrictions apply for this address.

See also Ordering and completion of data and instruction cache instructions on page D3-1706.

Data cache maintenance instructions (DC*)

The A64 assembly syntax for these instructions is described in System instructions on page C3-138.

Where an address argument for these instructions is required, it takes the form of a 64-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 64-bit register, the upper 32 bits of which are RES0.

DC ICAC requires write permission or else a Permission fault is generated.

A DC ICAC or DC ISW executed at Non-secure EL1 is performed by the PE as clean and invalidate, that is as a DC CIVAC or DC CISW, if both of the following apply:
- EL2 is implemented.
- HCR_EL2.VM is set to 1, meaning the second stage of address translation is enabled.

Note
This also applies to the AArch32 cache maintenance instructions DCIMVC and DCISW. see Data cache maintenance instructions (DC*) on page G3-4034.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see Out of range values of the Set/Way/Index fields in cache maintenance instructions on page J1-5451 or the instruction description.

If a memory fault that sets the FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.
**Note**

Despite its mnemonic, DC ZVA is not a cache maintenance instruction. For more information, see DC ZVA, Data Cache Zero by VA on page C5-326

See also Ordering and completion of data and instruction cache instructions on page D3-1706.

**EL0 accessibility to cache maintenance instructions**

The SCTLR_EL1.UCI bit enables EL0 access for the DC CVAU, DC CVAC, and DC CIVAC instructions. For these instructions read access permission is required. If the address specified in the argument cannot be read at EL0, executing the instruction at EL0 generates a Permission fault. When disabled, SCTLR_EL1.UCI == 0, these instructions generate a trap to EL1, that is reported using EC = 0x18.

In addition, SCTLR_EL1.UCT bit enables EL0 access to the Cache Type register, CTR_EL0. When software accesses the CTR_EL0 it can discover the stride necessary for cache maintenance instructions. When EL0 access to the Cache Type register is disabled, the instruction is trapped to EL1 using EC = 0x18.

**General requirements for the scope of maintenance instructions**

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page D3-1691, Behavior of caches at reset on page D3-1693, and Preloading caches on page B2-76.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

**Note**

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

**Effects of instructions that operate by VA to the Point of Coherency**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.
Table D3-4 shows the scope of the Data and unified cache maintenance instructions.

### Table D3-4 PEs affected by cache maintenance instructions to the Point of Coherency

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
</tbody>
</table>

### Effects of instructions operate by VA but not to the Point of Coherency

For these instructions, Table D3-5 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

### Table D3-5 PEs affected by cache maintenance instructions to the Point of Unification

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The point of unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable or Outer Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>

**Note**
The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

### Effects of All and set/way maintenance instructions

The **IC IALLU** and **DC set/way** instructions apply only to the caches of the PE that performs the instruction.

The **IC IALLUIS** instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

**Note**
The possible presence of system caches, as described in **System level caches on page D3-1710**, means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.
Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

Table D3-6 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the Specified entries are entries that the architecture requires the instruction to affect. The rules described in General behavior of the caches on page D3-1691 mean that an instruction might also affect other entries.

Table D3-6 Effects of virtualization and security on the maintenance instructions

</tbody>
</table>

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in The interaction of cache lockdown with cache maintenance instructions on page D3-1709 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.
In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.

- The AArch64 Data cache invalidate instructions, DC IVAC and DC ISW, at EL1 and EL0, and the AArch32 Data cache invalidate instructions DCIMVAC and DCISW, at EL1, perform a cache clean as well as a cache invalidation if both of the following apply:
  - The value of HCR.VM is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.

The means that, in Non-secure state:
- At EL1 using AArch64 or EL0 using AArch64, a DC IVAC instruction operates as DC CIVAC, and a DC ISW instruction operates as DC CISW.
- At EL1 using AArch32, a DCIMVAC instruction operates as DCCIMVAC, and a DCISW instruction operates as DCCISW.

- The AArch64 Data cache invalidate by set/way instruction DC ISW, at EL1 and EL0, and the AArch32 Data cache invalidate by set/way instruction DCISW, at EL1, perform a cache clean as well as a cache invalidation if both of the following apply:
  - The value of HCR_EL2.SWIO is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.

This means that, in Non-secure state:
- At EL1 using AArch64 or EL0 using AArch64, a DC ISW instruction operates as DC CISW.
- At EL1 using AArch32, a DC ISW instruction operates as DCCISW.

- When the value of HCR_EL2.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch64, this applies to the TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1, and IC IALLU instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example IC IALLU is upgraded to IC IALLUIS.

For more information about the cache maintenance instructions, see Overview of the cache maintenance instructions on page D3-1696, Cache maintenance instructions on page D3-1700, and Chapter D4 The AArch64 Virtual Memory System Architecture.

**Boundary conditions for cache maintenance instructions**

Cache maintenance instructions operate on the caches when the caches are enabled or when they are disabled.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.

- Any applicable domain control of the address accessed.

- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.
Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA, that specify an address:

- Execute in program order relative to loads or stores that access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.

- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.

- Execute in program order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.

- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

--- Note ---

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See Data and unified caches on page D4-1842.

- Data cache zero instruction on page D3-1708 describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

--- Note ---

These ordering requirements are extended from the requirements in AArch32 state given:

- Ordering of cache and branch predictor maintenance instructions on page G3-4040.
- Instruction cache maintenance instructions (IC*) on page G3-4034.
Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a processing element. However, unless all processing elements attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

In multi-processing environments, the cache maintenance instructions that operate by set/way are not broadcast within the shareability domains, and so allocations can occur from other, unmaintained, locations, in caches in other locations. For this reason, the use of cache maintenance instructions that operate by set/way for the maintenance of large buffers of memory is not recommended in the architectural sequence. The expected usage of the cache maintenance instructions that operate by set/way is associated with the cache maintenance instructions associated with the powerdown and powerup of caches, if this is required by the implementation.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```
MRS     X0, CLIDR_EL1
AND     W3, W0, #0x07000000     // Get 2 x Level of Coherence
LSR     W3, W3, #23
CBZ     W3, Finished
MOV     W10, #0                 // W10 = 2 x cache level
MOV     W8, #1                  // W8 = constant 0b1
Loop1:  ADD     W2, W10, W10, LSR #1    // Calculate 3 x cache level
        LSR     W1, W0, W2              // extract 3-bit cache type for this level
        AND     W1, W1, #0x7           // W1 = log2(linelen)-4
        CMP     W1, #2
        B.LT    Skip                    // No data or unified cache at this level
        MSR     CSSELR_EL1, X10         // Select this cache level
        ISB                             // Synchronize change of CSSELR
        MRS     X1, CCSIDR_EL1          // Read CCSIDR
        AND     W2, W1, #7              // W2 = log2(linelen)-4
        ADD     W2, W2, #4              // W2 = log2(linelen)
        UBFX    W4, W1, #3, #10        // W4 = max way number, right aligned
        CLZ     W5, W4                  // W5 = 32-log2(ways), bit position of way in DC operand
        LSL     W9, W4, W5              // W9 = max way number, aligned to position in DC operand
        LSL     W16, W8, W5             // W16 = amount to decrement way number per iteration
        Loop2:  UBFX    W7, W1, #13, #15       // W7 = max set number, right aligned
                 LSL     W7, W7, W2              // W7 = max set number, aligned to position in DC operand
                 LSL     W17, W8, W2             // W17 = amount to decrement set number per iteration
        Loop3:  ORR     W11, W10, W9            // W11 = combine way number and cache number ...
                 DC      CSW, X11              // Do data cache clean by set and way
                 SUBS    W7, W7, W17           // Decrement set number
                 B.GE   Loop3
        B.GE   Loop2
        Skip:   ADD     W10, W10, #2            // Increment 2 x cache level
                 CMP     W3, W10              // Ensure completion of previous cache maintenance operation
        B.GT    Loop1
Finished:
```
Similar approaches can be used for all cache maintenance instructions.

--- Note ---
Cache maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor systems, the use of cache maintenance to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations marked as cacheable. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

### D3.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, DC ZVA, writes 0b00 to each of a block of N bytes, aligned in memory to N bytes in size, where the block in memory is identified by the address passed. There are no alignment restrictions on the address supplied. The DCZID_EL0 register indicates the block size that is written with byte values of zero.

Software can restrict access to this operation. See Configurable instruction enables and disables, and trap controls on page D1-1558.

If disabled, the operation at EL0 is trapped to EL1.

The DC ZVA instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See Exception from a Data abort on page D1-1530 for more information about the encoding of ESR_ELx and the associated ISS field.
- If the memory region being zeroed is any type of Device memory, then DC ZVA generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

--- Note ---
The architecture makes no statements about whether or not a DC ZVA instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

### D3.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory; that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DC CSW.
  - Cache invalidate by set/way, DC ISW.
  - Cache clean and invalidate by set/way, DC CISW.
  - Instruction cache invalidate all, IC IALLU and IC IALLUIS.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See Exception from a Data abort on page D1-1530.

   This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DC CVAC and DC CVAU.
- Cache invalidate by virtual address, DC IVAC.
- Cache clean and invalidate by virtual address, DC CIVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See ESR_ELx on page J11-5819.

In an implementation that includes EL2, if HCR_EL2.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

--- Note ---

An implementation that uses an abort mechanisms for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.
**Additional cache functions for the implementation of lockdown**

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-263.

**D3.4.11 System level caches**

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as *system caches*.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

**D3.4.12 Branch prediction**

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.
D3.5 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. External aborts include parity or ECC errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page D1-1491.

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous aborts.

In AArch64 state, asynchronous aborts are reported using the SError interrupt exception. See Asynchronous exception types, routing, masking and priorities on page D1-1552.

Synchronous external aborts are reported using the Instruction Abort and Data Abort exceptions. See Synchronous exception types, routing and priorities on page D1-1545.

VMSAv8-64 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported.

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- External abort on an instruction fetch.
- External abort on data read or write.
- Provision for the classification of external aborts.
- Parity or ECC error reporting on page D3-1712.

D3.5.1 External abort on an instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous.

A synchronous external abort on an instruction fetch is taken precisely using the Instruction Abort exception. An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.2 External abort on data read or write

Externally-generated errors that occur during a data read or write can be either synchronous or asynchronous.

A synchronous external abort on a data read or write is taken precisely using the Data Abort exception. An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.3 Provision for the classification of external aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous external aborts. For more information, see Exception from an Instruction abort on page D1-1530 and Exception from a Data abort on page D1-1530.

For all aborts other than synchronous external aborts reported using the EC values 0x20, 0x21, 0x24, and 0x25, ESR_ELx.EA, ISS[9], returns a value of 0.
D3.5.4 Parity or ECC error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1520. However, when parity or ECC error reporting is implemented, it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the fault status encoding, parity or ECC errors are treated as external aborts.
D3.6 Memory barrier instructions

Memory barriers on page B2-87 describes the memory barrier instructions. This section describes the system level controls of those instructions.

D3.6.1 EL2 control of the shareability of data barrier instructions executed at Non-secure EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can upgrade the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table D3-7 shows the encoding of this field.

Table D3-7 EL2 control of shareability of barrier instructions executed at Non-secure EL0 or EL1

<table>
<thead>
<tr>
<th>HCR_EL2.BSU</th>
<th>Minimum shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1 in Non-secure state, Table D3-8 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

Table D3-8 Effect of HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL0

<table>

D3.7  Pseudocode description of general memory system instructions

This section contains the following pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access on page D3-1715.
- Aligned memory access on page D3-1715.
- Unaligned memory access on page D3-1716.
- Exclusive monitors operations on page D3-1717.
- Access permission checking on page D3-1719.
- Abort exceptions on page D3-1720.
- Memory barriers on page D3-1722.

D3.7.1  Memory data type definitions

This section describes the memory data type definitions.

The address descriptor type is defined as follows:

```plaintext
type AddressDescriptor is (  
    FaultRecord fault,  // fault.type indicates whether the address is valid  
    MemoryAttributes memattrs,  
    FullAddress address  
)
```

The full address type is defined as follows:

```plaintext
type FullAddress is (  
    bits(48) physicaladdress,  // '0' = Secure, '1' = Non-secure  
    bit NS  
)
```

The memory attributes types are defined as follows:

```plaintext
type MemoryAttributes is (  
    MemType type,  
    DeviceType device,  // For Device memory types  
    MemAttrHints inner,  // Inner hints and attributes  
    MemAttrHints outer,  // Outer hints and attributes  
    boolean shareable,  
    boolean outershareable  
)
```

The memory type is defined as follows.

```plaintext
enumeration MemType {MemType_Normal, MemType_Device};
```

The Device memory types are defined as follows:

```plaintext
enumeration DeviceType {DeviceType_GRE, DeviceType_nGRE, DeviceType_nGnRE, DeviceType_nGnRnE};
```

For Normal memory, the inner and outer attributes are defined as follows:

```plaintext
type MemAttrHints is (  
    bits(2) attrs,  // The possible encodings for each attributes field are as below  
    bits(2) hints,  // The possible encodings for the hints are below  
    boolean transient
)
```

The cacheability attributes are defined as follows:

```plaintext
constant bits(2) MemAttr_NC = '00';  // Non-cacheable  
constant bits(2) MemAttr_WT = '10';  // Write-through  
constant bits(2) MemAttr_WB = '11';  // Write-back
```
The allocation hints are defined as follows:

constant bits(2) MemHint_No = '00'; // No allocate
constant bits(2) MemHint_WA = '01'; // Write-allocate, Read-no-allocate
constant bits(2) MemHint_RA = '10'; // Read-allocate, Write-no-allocate
constant bits(2) MemHint_RWA = '11'; // Read-allocate and Write-allocate

The access permissions type is defined as follows:

type Permissions is (  
bits(3) ap,   // Access permission bits
    bit     xn,   // Execute-never bit
    bit     pxn   // Privileged execute-never bit
)

D3.7.2 Basic memory access

The two _Mem[] accessors, Non-assignment (memory read) and Assignment (memory write), are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

bits(8*size) _Mem[AddressDescriptor desc, integer size, AccType acctype];

_Mem[AddressDescriptor desc, integer size, AccType acctype] = bits(8*size) value;

The functions address the array using desc.paddress which supplies:

• A 48-bit physical address.
• A single NS bit to select between Secure and Non-secure parts of the array.

The AccType parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of AccType, see Address space on page B2-70.

The actual implemented array of memory might be smaller than the $2^{48}$ bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in memaddrdesc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page B2-93, Memory ordering on page B2-84, and Atomicity in the ARM architecture on page B2-81.

PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

integer PAMax();

D3.7.3 Aligned memory access

The MemSingle[] function makes an atomic, little-endian accesses of size bytes.

// AArch64.MemSingle[] - non-assignment (read) form
// -----------------------------------------------
// Perform an atomic, little-endian read of 'size' bytes.

bits(size*8) AArch64.MemSingle[bits(64) address, integer size, AccType acctype, boolean wasaligned]
assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);

AddressDescriptor memaddrdesc;
b bits(size*8) value;
iswrite = FALSE;

// MMU or MPU  
memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
    AArch64.Abort(address, memaddrdesc.fault);
D3 The AArch64 System Level Memory Model

D3.7 Pseudocode description of general memory system instructions

// Memory array access
value = _Mem[memaddrdesc, size, acctype];
return value;

// AArch64.MemSingle[] - assignment (write) form
// ==============================================================
// Perform an atomic, little-endian write of 'size' bytes.
AArch64.MemSingle[bits(64) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8)
value
assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);
AddressDescriptor memaddrdesc;
iswrite = TRUE;

// MMU or MPU
memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
AArch64.Abort(address, memaddrdesc.fault);

// Effect on exclusives
if memaddrdesc.memattrs.shareable then
ClearExclusiveByAddress(memaddrdesc.paddress, ProcessorID(), size);

// Memory array access
_Mem[memaddrdesc, size, acctype] = value;
return;

D3.7.4 Unaligned memory access

The Mem[] function makes an access of the required type. If that access is not architecturally defined to be atomic,
it synthesizes accesses from multiple calls to MemSingle[]. It also reverses the byte order if the access is big-endian.

// Mem[] - non-assignment (read) form
// ==============================================================
// Perform a read of 'size' bytes. The access byte order is reversed for a big-endian access.
// Instruction fetches would call AArch64.MemSingle directly.
bits(size*8) Mem[bits(64) address, integer size, AccType acctype]
assert size IN {1, 2, 4, 8, 16};
bits(size*8) value;
integer i;
boolean iswrite = FALSE;

aligned = AArch64.CheckAlignment(address, size, acctype, iswrite);
atomic = (aligned && !(acctype IN {AccType_VEC, AccType_VECSTREAM})) || size == 1;

if !atomic then
assert size > 1;
value<7:0> = AArch64.MemSingle[address, 1, acctype, aligned];

// For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
// access will generate an Alignment Fault, as to get this far means the first byte did
// not, so we must be changing to a new translation page.
if !aligned then
c = ConstrainUnpredictable();
assert c IN {Constraint_FAULT, Constraint_NONE};
if c == Constraint_NONE then aligned = TRUE;

for i = 1 to size-1
value<8*i+7:8*i> = AArch64.MemSingle[address+i, 1, acctype, aligned];
else
value = AArch64.MemSingle[address, size, acctype, aligned];
if BigEndian() then
    value = BigEndianReverse(value);
return value;

// Mem[] - assignment (write) form
// ================
// Perform a write of 'size' bytes. The byte order is reversed for a big-endian access.

Mem[bits(64) address, integer size, AccType acctype] = bits(size*8) value
integer i;
boolean iswrite = TRUE;

if BigEndian() then
    value = BigEndianReverse(value);

aligned = AArch64.CheckAlignment(address, size, acctype, iswrite);
atomic = (aligned && !(acctype IN {AccType_VEC, AccType_VECSTREAM})) || size == 1;

if !atomic then
    assert size > 1;
    AArch64.MemSingle[address, 1, acctype, aligned] = value<7:0>;

    // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
    // access will generate an Alignment Fault, as to get this far means the first byte did
    // not, so we must be changing to a new translation page.
    if !aligned then
        c = ConstrainUnpredictable();
        assert c IN {Constraint_FAULT, Constraint_NONE};
        if c == Constraint_NONE then aligned = TRUE;

        for i = 1 to size-1
            AArch64.MemSingle[address+i, 1, acctype, aligned] = value<8*i+7:8*i>;
    else
        AArch64.MemSingle[address, size, acctype, aligned] = value;
return;

The CheckAlignment() function is:
// AArch64.CheckAlignment()
// ================

boolean AArch64.CheckAlignment(bits(64) address, integer size, AccType acctype, boolean iswrite)
aligned = (address == Align(address, size));
A = SCTLR[].A;

if !aligned && (acctype == AccType_ATOMIC || acctype == AccType_Ordered || A == '1') then
    secondstage = FALSE;
    AArch64.Abort(address, AArch64.AlignmentFault(acctype, iswrite, secondstage));

return aligned;

D3.7.5 Exclusive monitors operations

The SetExclusiveMonitors() function sets the exclusive monitors for a block of bytes, the size of which is
determined by size, at the virtual address defined by address.

// AArch64.SetExclusiveMonitors()
// ================

// Sets the Exclusive Monitors for the current PE to record the addresses associated
// with the virtual address region of size bytes starting at address.
AArch64.SetExclusiveMonitors(bits(64) address, integer size)
acctype = AccType_ATOMIC;
iswrite = FALSE;
aligned = (address != Align(address, size));

memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, aligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
    return;
if memaddrdesc.memattrs.shareable then
    MarkExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);
MarkExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);
AArch64.MarkExclusiveVA(address, ProcessorID(), size);

The ExclusiveMonitorsPass() function checks whether the exclusive monitors are set to include the location of a number of bytes specified by size, at the virtual address defined by address. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to SetExclusiveMonitors().

// AArch64.ExclusiveMonitorsPass()
// ================================================================
// Return TRUE if the Exclusive Monitors for the current PE include all of the addresses
// associated with the virtual address region of size bytes starting at address.
// The immediately following memory write must be to the same addresses.
boolean AArch64.ExclusiveMonitorsPass(bits(64) address, integer size)

    // It is IMPLEMENTATION DEFINED whether the detection of memory aborts happens
    // before or after the check on the local Exclusive Monitor. As a result a failure
    // of the local monitor can occur on some implementations even if the memory
    // access would give an memory abort.
    acctype = AccType_ATOMIC;
iswrite = TRUE;
aligned = (address == Align(address, size));

    if !aligned then
        secondstage = FALSE;
        AArch64.Abort(address, AArch64.AlignmentFault(acctype, iswrite, secondstage));

    passed = AArch64.IsExclusiveVA(address, ProcessorID(), size);
    if !passed then
        return FALSE;

    memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch64.Abort(address, memaddrdesc.fault);

    passed = IsExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);
    if passed then
        ClearExclusiveLocal(ProcessorID());
        if memaddrdesc.memattrs.shareable then
            passed = IsExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

        return passed;

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

bit ExclusiveMonitorsStatus();
The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from address `paddress`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

```
MarkExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address `paddress`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

```
MarkExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns FALSE.

```
boolean IsExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The `IsExclusiveLocal()` function takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked an address range as exclusive access requested that covers all of `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of `size` bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

```
boolean IsExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

```
ClearExclusiveByAddress(FullAddress paddress, integer processorid, integer size);
```

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

```
ClearExclusiveLocal(integer processorid);
```

### D3.7.6 Access permission checking

The function `CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to `AArch64.NoFault()`.

The interpretation of access permission is shown in Memory access control on page D4-1800.

The pseudocode function for checking access permissions is as follows:

```
// AArch64.CheckPermission()
// ================
// Function used for permission checking from AArch64 stage 1 translations
```
FaultRecord AArch64.CheckPermission(Permissions perms, bits(64) vaddress, integer level, bit NS, AccType acctype, boolean iswrite)
assert !ELUsingAArch32(S1TranslationRegime());
wxn = SCTLR[].WXN == '1';
if PSTATE.EL IN {EL0,EL1} then
  priv_r = TRUE;
  priv_w = perms.ap<2> == '0';
  user_r = perms.ap<1> == '1';
  user_w = perms.ap<2:1> == '01';
  user_xn = perms.xn == '1' || (user_w && wxn);
  priv_xn = perms.pxn == '1' || (priv_w && wxn) || user_w;
  ispriv = PSTATE.EL != EL0 && acctype != AccType_UNPRIV;
  if ispriv then
    (r, w, xn) = (priv_r, priv_w, priv_xn);
  else
    (r, w, xn) = (user_r, user_w, user_xn);
elsif
  // Access from EL2 or EL3
  r = TRUE;
  w = perms.ap<2> == '0';
  xn = perms.xn == '1' || (w && wxn);
// Restriction on Secure instruction fetch
if HaveEL(EL3) && IsSecure() && NS == '1' && SCR_EL3.SIF == '1' then
  xn = TRUE;
if acctype == AccType_IFETCH then
  fail = xn;
elsif iswrite then
  fail = !w;
  failedread = FALSE;
else
  fail = !r;
  failedread = TRUE;
if fail then
  secondstage = FALSE;
  s2fs1walk = FALSE;
  ipaddress = bits(48) UNKNOWN;
  return AArch64.PermissionFault(ipaddress, level, acctype, !failedread, secondstage, s2fs1walk);
else
  return AArch64.NoFault();

D3.7.7 Abort exceptions

The Abort() function generates either a Data Abort or an Instruction Abort exception by calling AArch64.DataAbort() or AArch64.InstructionAbort(). It also can generate a debug exception for debug related faults, see Chapter D2 AArch64 Self-hosted Debug.

// AArch64.Abort()
// ===============
// Abort and Debug exception handling in an AArch64 translation regime.
AArch64.Abort(bits(64) vaddress, FaultRecord fault)
if IsDebugException(fault) then
  if fault.acctype == AccType_IFETCH then
    if UsingAArch32() & fault.debugmoe == DebugException_VectorCatch then
      AArch64.VectorCatchException(fault);
    else
      AArch64.BreakpointException(fault);
  else
    AArch64.BreakpointException(fault);
else
AArch64.WatchpointException(vaddress, fault);
elsif fault.acctype == AccType_IFETCH then
    AArch64.InstructionAbort(vaddress, fault);
else
    AArch64.DataAbort(vaddress, fault);

The DataAbort() function generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See Exception from a Data abort on page D1-1530. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, DataAbort() also sets the FAR to the VA of the abort.

The pseudocode for the DataAbort() function is as follows:

// AArch64.DataAbort()
// ===============
AArch64.DataAbort(bits(64) vaddress, FaultRecord fault)

route_to_el3 = HaveEL(EL3) && SCR_EL3.EA == '1' && IsExternalAbort(fault);
route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
(HCR_EL2.TGE == '1' || IsSecondStage(fault)));

bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
exception = AArch64.AbortSyndrome(Exception_DataAbort, fault, vaddress);

if PSTATE.EL == EL3 || route_to_el3 then
    AArch64.TakeException(EL3, exception, preferred_exception_return, vect_offset);
elsif PSTATE.EL == EL2 || route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

The InstructionAbort() function generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See Exception from an Instruction abort on page D1-1530. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, InstructionAbort() also sets the FAR to the VA of the abort.

The pseudocode for the InstructionAbort() function is as follows:

// AArch64.InstructionAbort()
// ================
AArch64.InstructionAbort(bits(64) vaddress, FaultRecord fault)

route_to_el3 = HaveEL(EL3) && SCR_EL3.EA == '1' && IsExternalAbort(fault);
route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
(HCR_EL2.TGE == '1' || IsSecondStage(fault)));

bits(64) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0;
exception = AArch64.AbortSyndrome(Exception_InstructionAbort, fault, vaddress);

if PSTATE.EL == EL3 || route_to_el3 then
    AArch64.TakeException(EL3, exception, preferred_exception_return, vect_offset);
elsif PSTATE.EL == EL2 || route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. Pseudocode description of the MMU faults on page D4-1824 provides a number of wrappers to generate FaultRecords.

The NoFault() function returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

```plaintext

type FaultRecord is (Fault    type,         // Fault Status
                    AccType  acctype,      // Type of access that faulted
                    bits(48) ipaddress,    // Intermediate physical address
                    boolean  s2fs1walk,    // Is on a Stage 1 page table walk
                    boolean  write,        // TRUE for a write, FALSE for a read
                    integer  level,        // For translation, access flag and permission faults
                    bit      extflag,      // IMPLEMENTATION DEFINED syndrome for external aborts
                    boolean  secondstage,  // Is a Stage 2 abort
                    bits(4)  domain,       // Domain number, AArch32 only
                    bits(4)  debugmoe)     // Debug method of entry, from AArch32 only

// AArch64.NoFault()
// ================
FaultRecord AArch64.NoFault()

    ipaddress = bits(48) UNKNOWN;
    level = integer UNKNOWN;
    acctype = AccType_NORMAL;
    iswrite = boolean UNKNOWN;
    extflag = bit UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch64.CreateFaultRecord(Fault_None, ipaddress, level, acctype, iswrite, extflag, secondstage, s2fs1walk);

// IsFault()
// =========
// Return true if a fault is associated with an address descriptor

boolean IsFault(AddressDescriptor addrdesc)

    return addrdesc.fault.type != Fault_None;
```

**D3.7.8 Memory barriers**

The definition for the memory barrier functions is:

```plaintext
equation MBReqDomain    {MBReqDomain_Nonshareable, MBReqDomain_InnerShareable, MBReqDomain_OuterShareable, MBReqDomain_FullSystem};

equation MBReqTypes     {MBReqTypes_Reads, MBReqTypesWrites, MBReqTypes_All};
```
These functions define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The following procedures perform the memory barriers:

DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);
DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);
InstructionSynchronizationBarrier();
D3 The AArch64 System Level Memory Model
D3.7 Pseudocode description of general memory system instructions
Chapter D4
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

- About the Virtual Memory System Architecture (VMSA) on page D4-1726.
- The VMSAv8-64 address translation system on page D4-1728.
- Translation table walk examples on page D4-1779.
- VMSAv8-64 translation table format descriptors on page D4-1791.
- Access controls and memory region attributes on page D4-1800.
- MMU faults on page D4-1816.
- Translation Lookaside Buffers (TLBs) on page D4-1825.
- Caches in a VMSA implementation on page D4-1842.
D4.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the Virtual Memory System Architecture (VMSA) that applies to a PE executing in AArch64 state. This is VMSAv8-64, as defined in ARMv8 VMSA naming on page D4-1730.

A VMSA provides a Memory Management Unit (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The process of address translation maps the virtual addresses (VAs) used by the PE onto the physical addresses (PAs) of the physical memory system. These translations are defined independently for different Exception levels and Security states, and Figure D4-1 shows.

Address translations when EL3 is using AArch64

Secure EL3 VA ——— Secure EL3 stage 1 ——— PA, Secure or Non-secure

Secure EL1&0 VA ——— Secure EL1&0 stage 1 ——— PA, Secure or Non-secure

Non-secure EL2 VA ——— Non-secure EL2 stage 1 ——— PA, Non-secure only

Non-secure EL1&0 VA ——— Non-secure EL1&0 stage 1 ——— IPA ——— Non-secure EL1&0 stage 2 ——— PA, Non-secure only

Figure D4-1 Address translations for different Exception levels and Security states

VMSAv8-64 supports tagging of VAs, as described in Address tagging in AArch64 state. As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. The implemented Exception levels and the resulting translation stages and regimes on page D4-1763 describes the differences in the VMSA if some Exception levels are not implemented.

D4.1.1 Address tagging in AArch64 state

In AArch64 state, the ARMv8 architecture supports tagged addresses for data values. In these cases the top eight bits of the virtual address are ignored when determining:

- Whether the address causes a Translation fault from being out of range if the translation system is enabled.
- Whether the address causes an Address size fault from being out of range if the translation system is not enabled.
- Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

For addresses using the VMSAv8-64 EL1&0 translation regime

The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

VA[55]=0 TCR_EL1.TBI0 determines whether address tags are used. If stage 1 translation is enabled, TTBR0_EL1 holds the base address of the translation tables used to translate the address.

VA[55]=1 TCR_EL1.TBI1 determines whether address tags are used. If stage 1 translation is enabled, TTBR1_EL1 holds the base address of the translation tables used to translate the address.

For addresses using the VMSAv8-64 EL2 translation regime

TCR_EL2.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_EL2 holds the base address of the translation tables used to translate the address.

For addresses using the VMSAv8-64 EL3 translation regime

TCR_EL3.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_EL3 holds the base address of the translation tables used to translate the address.
The TCR_ELx.TBI\textsubscript{n} bits determine whether address tags are used regardless of whether the corresponding translation regime is enabled.

An address tag enable bit also has an effect on the PC value in the following cases:

- Any branch or procedure return within the controlled Exception level.
- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- On performing an exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.
- Exiting from debug state to the controlled Exception level.

As an example of what is meant by the *controlled Exception level*, TCR_EL2.TBI controls this effect for:

- A branch or procedure return within EL2.
- Taking an exception to EL2.
- Performing an exception return or a debug state exit to EL2.

The effect of the controlling TBI\{n\} bit is:

**For EL0 or EL1**
If the controlling TBI\{n\} bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign extension of bit[55] of that address.

**For EL2 or EL3**
If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be 0x00.

The \texttt{AddrTop()} pseudocode function shows the algorithm determining the most significant bit of the VA, and therefore whether the virtual address is using tagging. For the EL1&0 translation regime, this pseudocode includes the selection between TTBR0_EL1 and TTBR1_EL1 described in the Selection between TTBR0 and TTBR1 on page D4-1755.

```plaintext
// AddrTop()
// =========
integer AddrTop(bits(64) address)
// Return the MSB number of a virtual address in the current stage 1 translation
// regime. If EL1 is using AArch64 then addresses from EL0 using AArch32
// are zero-extended to 64 bits.
if UsingAArch32() && !(PSTATE.EL == EL0 && !ELUsingAArch32(EL1)) then
  // AArch32 translation regime.
  return 31;
else
  // AArch64 translation regime.
  case PSTATE.EL of
    when EL0, EL1
      tbi = if address<55> == '1' then TCR_EL1.TBI1 else TCR_EL1.TBI0;
    when EL2
      tbi = TCR_EL2.TBI;
    when EL3
      tbi = TCR_EL3.TBI;
  return (if tbi == '1' then 55 else 63);
```

The required behavior prevents a tagged address being propagated to the program counter.

When address tagging is enabled for an address that causes a Data Abort or a Watchpoint, the address tag is included in the virtual address returned in the FAR.
D4.2 The VMSAv8-64 address translation system

This section describes the VMSAv8-64 address translation system, that maps VAs to PAs. Related to this:

- Translation table walk examples on page D4-1779 gives detailed descriptions of typical examples of translating a VA to a final PA, and obtaining the memory attributes of that PA.
- VMSAv8-64 translation table format descriptors on page D4-1791 describes the translation table entries.
- Access controls and memory region attributes on page D4-1800 describes the attributes that are held in the translation table entries, including how different attributes can interact.
- Translation Lookaside Buffers (TLBs) on page D4-1825 describes the caching of translation table lookups in TLBs, and the architected instructions for maintaining TLBs.

In this section, the following subsections describe the VMSAv8-64 address translation system:

- About the VMSAv8-64 address translation system.
- Controlling address translation stages on page D4-1732.
- Memory translation granule size on page D4-1736.
- Translation tables and the translation process on page D4-1741.
- Overview of the VMSAv8-64 address translation stages on page D4-1743.
- The VMSAv8-64 translation table format on page D4-1752.
- The algorithm for finding the translation table entries on page D4-1758.
- The effects of disabling a stage of address translation on page D4-1761.
- The implemented Exception levels and the resulting translation stages and regimes on page D4-1763.
- Pseudocode description of VMSAv8-64 address translation on page D4-1764.
- Address translation instructions on page D4-1775.

D4.2.1 About the VMSAv8-64 address translation system

The Memory Management Unit (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an input address (IA), and either:

- Returns an associated output address (OA), and the memory attributes for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. An MMU fault is generated by a particular stage of translation, and can be described as either a stage 1 MMU fault or a stage 2 MMU fault.

The process of mapping an IA to an OA is an address translation, or more precisely a single stage of address translation.

The architecture defines a number of translation regimes, where a translation regime comprises either:

- A single stage of address translation.
  This maps an input Virtual Address (VA) to an output Physical Address (PA).
- Two, sequential, stages of address translation, where:
  — Stage 1 maps an input VA to an output Intermediate Physical Address (IPA).
  — Stage 2 maps an input IPA to an output PA.

The translation granule specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The page size for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.
The MMU is controlled by System registers, that provide independent control of each address translation stage, including a control to disable the stage of address translation. The effects of disabling a stage of address translation on page D4-1761 defines how the MMU handles an access for which a required address translation stage is disabled.

--- Note ---

- In the ARM architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between IPA and PA.

- A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
  - Returns an OA that equals the IA. This is called a flat mapping of the IA to the OA.
  - Does not change the memory attributes returned by the stage 1 address translation.

For an access to a stage of address translation that does not generate an MMU fault, the MMU translates the IA to the corresponding OA. System registers are used to report any faults that occur on a memory access.

This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64. Figure D4-2 shows these translation stages and translation regimes when EL3 is using AArch64.

For more information, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1795.
The following subsections give more information:

- ARMv8 VMSA naming.
- VMSA address types and address spaces.
- About address translation on page D4-1731.
- The VMSAv8-64 translation table format on page D4-1731.

ARMv8 VMSA naming

The ARMv8 VMSA naming model reflects the possible stages of address translation, as follows:

- **VMSAv8**: The overall translation scheme, within which an address translation has one or two stages.
- **VMSAv8-32**: The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32.
- **VMSAv8-64**: The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64.

VMSA address types and address spaces

A description of the VMSA refers to the following address types.

Note

These descriptions relate to the VMSAv8 description and therefore give more detail than the generic definitions given in the glossary.

Virtual Address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

Note

This means that an address held in the PC, LR, SP, or an ELR, is a VA.

In AArch64 state, the VA address space has a maximum address width of 48 bits. With a single VA range this gives a maximum VA space of 256TB, with VA range of $0x0000_0000_0000_0000$ to $0x0000_FFFF_FFFF_FFFF$.

However, for the EL1&0 translation stage the VA range is split into two subranges, one at the bottom of the full 64-bit address range of the PC, and one at the top, as follows:

- The bottom VA range runs up from address $0x0000_0000_0000_0000$. With the maximum address width of 48 bits this gives a VA range of $0x0000_0000_0000_0000$ to $0x0000_FFFF_FFFF_FFFF$.
- The top VA subrange runs up to address $0xFFFF_FFFF_FFFF_FFFF$. With the maximum address width of 48 bits this gives a VA range of $0xFFFF_0000_0000_0000$ to $0xFFFF_FFFF_FFFF_FFFF$. Reducing the address width for this subrange increases the bottom address of the range.

This means that there are two VA subranges, each of up to 256TB.

Each translation regime, that takes a VA as an input address, can be configured to support fewer than 48 bits of virtual address space, see Address size configuration on page D4-1733.

Intermediate Physical Address (IPA)

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
- The IA for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA. Alternatively, the translation regime can be considered as having no concept of IPAs.

The IPA address space has a maximum address width of 48 bits, see Address size configuration on page D4-1733.
Physical Address (PA)

The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3 and Secure EL1 Exception levels provide independent definitions of physical address spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure physical address space.
- When in Non-secure state, a VA is always mapped to the Non-secure physical address space.

Each PA address space has a maximum address width of 48 bits, but an implementation can implement fewer than 48 bits of physical address. See Address size configuration on page D4-1733.

About address translation

For a single stage of address translation, a Translation table base register (TTBR) indicates the start of the first translation table required for the mapping from input address to output address. Each implemented translation stage shown in VMSAv8 AArch64 translation regimes, translation stages, and associated controls on page D4-1729 requires its own set of translation tables.

For the EL1&0 stage 1 translation, the split of the VA mapping into two subranges requires two tables, one for the lower part of the VA space, and the other for the upper part of the VA space. Example use of the split VA range, and the TTBR0_EL1 and TTBR1_EL1 controls on page D4-1756 shows how these ranges might be used.

Controlling address translation stages on page D4-1732 summarizes the system control registers that control address translation by the MMU.

A full translation table lookup is called a translation table walk. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a level of address lookup. The final level of the lookup defines:

- The high bits of the required output address.
- The attributes and access permissions of the addressed memory.

Translation table entries can be cached in a Translation Lookaside Buffer, see Translation Lookaside Buffers (TLBs) on page D4-1825.

The VMSAv8-64 translation table format

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

Note

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the ARMv7 Large Physical Address Extension, and extended slightly by ARMv8. VMSAv8-32 also supports a Short-descriptor translation table format. Chapter G4 The AArch32 Virtual Memory System Architecture describes both of these formats.

The VMSAv8-64 translation table format provides:

- Up to four levels of address lookup.
- Input addresses of up to 48 bits.
- Output addresses of up to 48 bits.
- A translation granule size of 4KB, 16KB, or 64KB.
D4.2.2 Controlling address translation stages

*The implemented Exception levels and the resulting translation stages and regimes on page D4-1763 defines the translation regimes and stages. For each supported address translation stage:*

- A system control register bit enables the stage of address translation.
- A system control register bit determines the endianness of the translation table lookups.
- A *Translation Control Register* (TCR) controls the stage of address translation.
- If a stage of address translation supports splitting the VA range into two subranges then that stage of translation provides a *Translation Table Base Register* (TTBR) for each VA subrange, and the stage of address translation has:
  - A single TCR.
  - A TTBR for each VA subrange.

Otherwise, a single TTBR holds the address of the translation table that must be used for the first lookup for the stage of address translation.

For address translation stages controlled from AArch64:

- *Table D4-1* shows the endianness bit and the enable bit for each stage of address translation. Each register entry in the table gives the endianness bit followed by the enable bit. Except for the Non-secure EL1&0 stage 2 translation, these two bits are in the same register.

  **Table D4-1 Enable and endianness bits for the AArch64 translation stages**

<table>
<thead>
<tr>
<th>Translation stage</th>
<th>Controlled from</th>
<th>Controlling register</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Non-secure EL1&amp;0 stage 1</td>
<td>Non-secure EL1</td>
<td>SCTLR_EL1.{EE, M}</td>
</tr>
</tbody>
</table>

**Note**

If the PA of the software that enables or disables a particular stage of address translation differs from its VA, speculative instruction fetching can cause complications. ARM strongly recommends that the PA and VA of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

- *Table D4-2* shows the TCR and TTBR, or TTBRs, for each stage of address translation. In the table, each *Controlling registers* entry gives the TCR followed by the TTBR or TTBRs.

  **Table D4-2 TCRs and TTBRs for the AArch64 translation stages**

System control registers relevant to MMU operation

In AArch64 state, system control registers have a suffix, that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a Common abbreviation for each of the system control registers that affects MMU operation, as Table D4-3 shows. The common abbreviation is used when describing features that apply to all the translation regimes.

Note
The only translation regime that supports a stage 2 translation is the Non-secure EL1&0 translation regime.

Table D4-3 Abbreviations for system control registers used in this chapter

Address size configuration

The following subsubsections specify the configuration of the physical address size and of the input and output address sizes for each of the stages of address translation:

- Physical address size.
- Output address size on page D4-1734.
- Input address size on page D4-1734.
- Supported IPA size on page D4-1735.

Physical address size

The ID_AA64MMFR0_EL1.PARange field indicates the implemented physical address size, as Table D4-4 shows.

Table D4-4 Physical address size implementation options

<table>
<thead>
<tr>
<th>ID_AA64MMFR0_EL1.PARange</th>
<th>Total PA size</th>
<th>PA address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>

</tr>
<tr>
<td>0011</td>
<td>4 TB</td>
<td>42 bits, PA[41:0]</td>
</tr>
<tr>
<td>0100</td>
<td>16 TB</td>
<td>44 bits, PA[43:0]</td>
</tr>
<tr>
<td>0101</td>
<td>256 TB</td>
<td>48 bits, PA[47:0]</td>
</tr>
</tbody>
</table>

All other PARange values are reserved.
**Output address size**

For each enabled stage of address translation, \( \text{TCR.}\{I\}PS \) must be programmed to maximum output address size for that stage of translation, using the encodings as shown in Table D4-5.

<table>
<thead>
<tr>
<th>( \text{TCR.}{I}PS )</th>

<td>44 bits, PA([43:0])</td>
</tr>
<tr>
<td>101</td>
<td>256 TB</td>
<td>48 bits, PA([47:0])</td>
</tr>
</tbody>
</table>

--- **Note** ---

- This field is called IPS in the TCR_EL1, and PS in the other TCRs.
- The \( \{I\}PS \) fields are 3-bit fields, corresponding to the least-significant PARange bits shown in Table D4-4 on page D4-1733.

If \( \{I\}PS \) is programmed to a value larger than the implemented physical address size, then the PE behaves as if programmed with the implemented physical address size, but software must not rely on this behavior. That is, the output address size is never larger than the implemented physical address size. Table D4-4 on page D4-1733 shows the implemented physical address size.

The PE checks that the TTBR, translation table entries, and the output address for the stage of address translation have the address bits above the output address size set to zero. If this is not the case, an Address size fault is generated for the level and stage of translation that caused the fault. An Address size fault from the TTBR is reported as a level 0 fault.

If stage 1 translation is disabled and the input address is larger than the implemented physical address size, then a stage 1 level 0 Address size fault is generated.

When using two stages of translation:

- If stage 2 translation is disabled and the output address from the stage 1 translation is larger than the implemented physical address size, then a stage 1 Address size fault is generated for the level of the stage 1 translation that generated the output address.

- If stage 2 translation is enabled and the output address from the stage 1 translation does not generate a stage 1 Address Size fault, but is larger than the input address size specified for the stage 2 translation, then a stage 2 Translation fault is generated.

**Input address size**

For each enabled stage of address translation, the \( \text{TCR.T}x\text{SZ} \) fields specify the input address size:

- \( \text{TCR_EL1} \) has two \( Tx\text{SZ} \) fields, corresponding to the two VA subranges:
  - \( \text{TCR_EL1.T0SZ} \) specifies the size for the lower VA range, translated using TTBR0_EL1.
  - \( \text{TCR_EL1.T1SZ} \) specifies the size for the upper VA range, translated using TTBR1_EL1.

- Each of the other TCRs has a single T0SZ field.

For the Non-secure EL1&0 translation regime, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address specified by VTCR_EL2.T0SZ, then the input address size check for the stage 2 translation generates a Translation fault.
Overview of the VMSAv8-64 address translation stages on page D4-1743 gives more information about the relationship between the required input address size, the value of T_xSZ, and the required initial lookup level, and how these are affected by the translation granule size. However:

For all translation stages

The maximum T_xSZ value is 39. If T_xSZ is programmed to a value larger than 39 then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field is programmed to 39 for all purposes other than reading back the value of the field.
- Any use of the T_xSZ value generates a Level 0 Translation fault for the stage of translation at which T_xSZ is used.

For a stage 1 translation

The minimum T_xSZ value is 16. If T_xSZ is programmed to a value smaller than 16 then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.
- Any use of the T_xSZ value generates a stage 1 Level 0 Translation fault.

For a stage 2 translation

Supported IPA size defines the effective minimum value of T0SZ, that depends on the supported PA size, and also describes the possible effects of programming T0SZ to a value that is smaller than this effective minimum value.

Supported IPA size

For the Non-secure EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation, that must be specified by VTCR_EL2.T0SZ, see Input address size on page D4-1734. This value is constrained by the implemented PA size that is specified by ID_AA64MMFR0_EL1.PARange, see Physical address size on page D4-1733. This implemented PA size also constrains the maximum value of VTCR_EL2.SL0, that specifies the level of the initial lookup. SL0 also depends on the translation granule, as described in Overview of the VMSAv8-64 address translation stages on page D4-1743.

If VTCR_EL2.SL0 is programmed to a value larger than the maximum value shown in Table D4-6 then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.
If VTCR_EL2.T0SZ is programmed to a value smaller than the effective minimum value shown in Table D4-6 on page D4-1735 then the implementation consistently does one of the following:

- Treat the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.
- Treat the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than:
  - Reading back the value of the field.
  - Checking whether the value of VTCR_EL2.T0SZ is consistent with the value of VTCR_EL2.SL0.
- Generate a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

--- Note ---

Programming VTCR_EL2.T0SZ to a value smaller than the effective minimum value shown in Table D4-6 on page D4-1735 can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

- The PA size, for a VMSAv8-64 stage 1 translation.
- 40 bits, for a VMSAv8-32 stage 1 translation.

### D4.2.3 Memory translation granule size

The memory translation granule size defines both:

- The maximum size of a single translation table.
- The memory page size. That is, the granularity of a translation table lookup.

VMSAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB, and each translation stage is configured to use one of these granule sizes.

--- Note ---

Using a larger granule size can reduce the maximum required number of levels of address lookup because:

- The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
- The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.

Table D4-7 summarizes the effects of the different granule sizes.

<table>
<thead>

</tr>
</tbody>
</table>
How the granule size affects the address translation process

As Table D4-7 on page D4-1736 shows, the translation granule determines the number of address bits:

- Required to address a memory page.
- That can be resolved in a single translation table lookup.

This means the translation granule determines how the *input address* (IA) is resolved to an *output address* (OA) by the translation process.

Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple *levels* of lookup.

Considering the resolution of the maximum IA range of 48 bits, with a translation granule size of $2^n$ bytes:

- The least-significant $n$ bits of the IA address the memory page. This means OA$[(n-1):0]$ = IA$[(n-1):0]$.
- The remaining (48-$n$) bits of the IA, IA$[47:n]$, must be resolved by the address translation.
- A translation table descriptor is 8 bytes. Therefore:
  - A complete translation table holds $2^{(n-3)}$ descriptors.
  - A single level of translation can resolve a maximum of $(n-3)$ bits of address.

Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because a level of lookup can resolve $(n-3)$ bits of address:

- The final level of lookup resolves IA$[(2n-4):n]$.
- The previous level of lookup resolves IA$[(3n-7):(2n-3)]$.

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, the address bits resolved in a level of lookup are:

$$\text{IA}[\text{Min}(47, (x(n-3)+2n-4):(n+(x-3)(n-3))],$$

where:

\[ \text{Min}(a, b) \text{ is a function that returns the minimum of } a \text{ and } b. \]

\[ x \text{ indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.} \]

The following diagrams show this model, for each of the permitted granule sizes.

**Figure D4-3** shows how a 48-bit IA is resolved when using the 4KB translation granule.

![Diagram showing how a 48-bit IA is resolved when using the 4KB translation granule](image-url)
Figure D4-4 shows how a 48-bit IA is resolved when using the 16KB translation granule.

\(^a\) Smaller value than indicated in Table D4-8, as explained in this section.
\(^b\) Level 0 lookup not possible with 64KB granule size

Table D4-8 refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the ARMv8 translation system supports the following possible variations from the information in Table D4-8:

Reduced IA width

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. For each 1 bit reduction in the input address size the size of the translation table is halved.

\[\text{Note}\]

- This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.
- For a stage 2 translation, it might be possible to start the translation at a lower level, see Concatenated translation tables on page D4-1740.

- More low-order TTBR bits are needed to hold the translation table base address.

Example D4-1 on page D4-1740 shows how this applies to translating a 35-bit input address range using the 4KB granule.
Example D4-1 Effect of an IA width of 35 bits when using the 4KB granule size

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, IA[34:0], Table D4-9 on page D4-1739 shows that lookup must start at level 1, and that the initial lookup must resolve IA[34:30], meaning it resolves 5 bits of address: This 4-bit reduction in the required resolution means:

- The translation table size is divided by 2^4, giving a size of 256B.
- The TTBR requires 4 more bits for the translation table base address, which becomes TTBR[47:8].

When using the 64KB translation granule to translate the maximum IA size of 48 bits, Table D4-9 on page D4-1739 shows that a level 1 lookup must resolve only IA[47:42]. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by 2^7, giving a size of 512B.
- The TTBR requires 7 more bits for the translation table base address, which becomes TTBR[47:9].

Concatenated translation tables

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. Each additional IA bit resolved:

- Doubles the number of translation tables required. Resolving an additional \( n \) bits requires \( 2^n \) concatenated translation tables at the initial lookup level.
- Reduces by 1 bit the width of the translation table base address held in the TTBR.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in Table D4-9 on page D4-1739 can be extended by up to 4 bits. Example D4-2 shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

Example D4-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule

Table D4-9 on page D4-1739 shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:

- Two translation tables are concatenated, giving a total size of 8KB.
- The TTBR requires 1 fewer bit for the translation table base address, which becomes TTBR[47:13].

For more information, see Concatenated translation tables for the initial stage 2 lookup on page D4-1756.

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.

The translation table base address held in the TTBR is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has an OA size of 48 bits, meaning the translation table base address is:

- TTBR[47:12] if using the 4KB translation granule.
- TTBR[47:14] if using the 16KB translation granule.
- TTBR[47:16] if using the 64KB translation granule.

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:

- If using the 4KB translation granule:
  - TTBR[47:40] must be set to zero.
  - TTBR[39:12] holds the translation table base address.
If using the 16KB translation granule:
— TTBR[47:40] must be set to zero.

If using the 64KB translation granule:
— TTBR[47:40] must be set to zero.
— TTBR[39:16] holds the translation table base address.

In all cases, if TTBR[47:40] is not zero, any attempt to access the translation table generates an Address size fault.

### D4.2.4 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- **Translation table walks.**
- **Security state of translation table lookups on page D4-1743.**
- **Control of translation table walks on page D4-1743.**
- **Security state of translation table lookups on page D4-1743.**

See also **Selection between TTBR0 and TTBR1** on page D4-1755.

#### Translation table walks

A translation table walk comprises one or more translation table lookups. The translation table walk is the set of lookups that are required to translate the virtual address to the physical address. For the Non-secure EL1&0 translation regime, this set includes lookups for both the stage 1 translation and the stage 2 translation. The information returned by a successful translation table walk is:

- The required physical address. If the access is from Secure state this includes identifying whether the access is to the Secure physical address space or the Non-secure physical address space, see **Security state of translation table lookups** on page D4-1743.

- The memory attributes for the target memory region, as described in **Memory types and attributes on page B2-93.** For more information about how the translation table descriptors specify these attributes see **Memory region attributes on page D4-1808.**

- The access permissions for the target memory regions. For more information about how the translation table descriptors specify these permissions see **Memory access control on page D4-1800.**

The translation table walk starts with a read of the translation table for the initial lookup. The TTBR for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor, that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.

- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
  — The descriptor provides hierarchical attributes that are applied to the final translation, see **Hierarchical control of Secure or Non-secure memory accesses on page D4-1798** and **Hierarchical control of data access permissions on page D4-1802.**
  — If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.

- The descriptor is invalid. In this case, the memory access generates a Translation fault.

**Figure D4-6 on page D4-1742** gives a generalized view of a single stage of address translation, where three levels of lookup are required.
A translation table lookup from VMSAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness. SCTLR.EE determines the endianness of the translation table lookups.

Dynamically changing translation table endianness
Because any change to an SCTLR.EE, bit requires synchronization before it is visible to subsequent operations, ARM strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.

Address translation stages are disabled by setting an SCTLR.M bit to 0. See the appropriate register description for more information.

The appropriate TTBR holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than Non-secure EL1&0 stage 1 translations, the output address held in the TTBR, and any translation table base address returned by a translation table descriptor, is the PA of the base of the translation table.
- For Non-secure EL1&0 stage 1 translations, the output address held in the TTBR, and any translation table base address returned by a translation table descriptor, is the IPA of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

The TTBR also determines the memory cacheability and shareability attributes that apply, for that stage of translation, to all translation table lookups generated by that stage of translation.
The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

**Note**

- In a two stage translation system, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. ARM strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see *Stage 2 fault on a stage 1 translation table walk* on page D4-1822.

- The rules about mismatched attributes given in *Mismatched memory attributes* on page B2-104 apply to the relationship between translation table walks and explicit memory accesses to the translation tables in the same way that they apply to the relationship between different explicit memory accesses to the same location. For this reason, ARM strongly recommends that the attributes that the TTBR applies to the translation tables are the same as the attributes that are applied for explicit accesses to the memory that holds the translation tables.

For more information see *Overview of the VMSAv8-64 address translation stages*.

See also *Selection between TTBR0 and TTBR1* on page D4-1755.

**Security state of translation table lookups**

For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.

For a Secure translation regimes, the initial translation table lookup is performed to a Secure output address.

If the translation table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to Secure or to Non-secure output addresses.

This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any translation table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

**Control of translation table walks**

For the first stage of the EL1&0 translation regime, the TCR_EL1.{EPD0, EPD1} bits determine whether the translation tables for that regime are valid. EPD0 indicates whether the table that TTBR0_EL1 points to is valid, and EPD1 indicates whether the table that TTBR1_EL1 points to is valid. The effect of these bits is:

- \( \text{EPD}_n = 0 \) The translation table is valid, and can be used for a translation table lookup.
- \( \text{EPD}_n = 1 \) If a TLB miss occurs based on TTBR\(_n\), a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.

### D4.2.5 Overview of the VMSAv8-64 address translation stages

As shown in *Memory translation granule size* on page D4-1736, the granule size determines significant aspects of the address translation process. *Effect of granule size on translation table addressing and indexing* on page D4-1739 shows, for each granule size:

- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in *Concatenated translation tables* on page D4-1740.
- The TTBR addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:

- *Overview of VMSAv8-64 address translation using the 4KB translation granule* on page D4-1744.
- *Overview of VMSAv8-64 address translation using the 16KB translation granule* on page D4-1746.
- *Overview of VMSAv8-64 address translation using the 64KB translation granule* on page D4-1750.
Overview of VMSAv8-64 address translation using the 4KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR.TxSZ field. When using the 4KB translation granule, Table D4-10 shows this requirement.

Table D4-10 TCR.TnSZ values and IA ranges when there is no concatenation of translation tables

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>TnSZ values for and input address ranges(a) for starting at this level</th>

</tr>
</tbody>
</table>

\(a\) The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

Figure D4-7 shows the stage 1 address translation, for an address translation using the 4KB granule with an input address size greater than 39 bits.

Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see Concatenated translation tables for the initial stage 2 lookup on page D4-1756.
When using the 4KB translation granule, Table D4-11 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-11 VTCR_EL2.T0SZ values and IA ranges, including cases where translation tables are concatenated

<table>
<thead>

</tbody>
</table>

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, see Table D4-10 on page D4-1744.

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.

--- Note ---

• When using the 4KB translation granule, the initial lookup cannot be at level 3.

• Because concatenating translation tables reduces the number of levels of lookup required, when using the 4KB translation granule, tables cannot be concatenated at level 0.

• Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-12 shows.

Table D4-12 VTCR_EL2.SL0 values, 4KB granule

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>VTCR_EL2.SL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero</td>
<td>0b10</td>
</tr>
<tr>
<td>One</td>
<td>0b01</td>
</tr>
<tr>
<td>Two</td>
<td>0b00</td>
</tr>
</tbody>
</table>

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, a stage 2 level 0 translation fault is generated.

Figure D4-8 on page D4-1746 shows the stage 2 address translation, for an input address size of between 40 and 43 bits. This means the lookup can start at either the level 0 or the level 1.
Overview of VMSAv8-64 address translation using the 16KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 16KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR.TxSZ field. When using the 16KB translation granule, Table D4-13 shows this requirement.

Table D4-13 TCR.TnSZ values and IA ranges when there is no concatenation of translation tables

</table>
a. The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations, but stage 2 translation does not permit an initial lookup at level 0.

--- Note ---

• When using the 16KB translation granule, a maximum of 1 bit of IA is resolved by a level 0 lookup.

• Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

Figure D4-9 shows the stage 1 address translation, for an address translation using the 16KB granule with an input address size of 48 bits.

--- Figure D4-9 General view of VMSAv8-64 stage 1 address translation, 16KB granule ---

**Overview of stage 2 translations, 16KB granule**

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see *Concatenated translation tables for the initial stage 2 lookup* on page D4-1756.

When using the 16KB granule, for a stage 2 translation with an input address sized of 48 bits, the initial lookup must be at level 1, with two concatenated translation tables at this level.
When using the 16KB translation granule, Table D4-14 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-14 VTCR_EL2.T0SZ values and IA ranges, including cases where translation tables are concatenated

<table>

<td>16</td>
<td>IA[47:14]</td>
<td>-</td>
</tr>
</tbody>
</table>

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, see Table D4-10 on page D4-1744.

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.

---

**Note**

- When using the 16KB translation granule for a stage 2 translation, the initial lookup cannot be at level 0. When a 48-bit input address is required, translation must start with a level 1 lookup using two concatenated translation tables.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

---

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-15 shows.

Table D4-15 VTCR_EL2.SL0 values, 16KB granule

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>VTCR_EL2.SL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>One</td>
<td>0b10</td>
</tr>
<tr>
<td>Two</td>
<td>0b01</td>
</tr>
<tr>
<td>Three</td>
<td>0b00</td>
</tr>
</tbody>
</table>

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.T0SZ, SL0 values. If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, a stage 2 level 0 translation fault is generated.
When stage 2 translation supports a 48-bit input address range, translation must start with a level 1 lookup using two concatenated translation tables. Figure D4-10 shows the translation for this case.

However, for an input address size of between 37 and 40 bits, Table D4-14 on page D4-1748 shows that translation can start with either a level 1 lookup or a level 2 lookup, and Figure D4-11 shows these options.

VTCR_EL2.SL0 defines the start level.

Figure D4-10 VMSAv8-64 stage 2 address translation, 16KB granule, 48 bit input address

Figure D4-11 General view of VMSAv8-64 stage 2 address translation, 16KB granule
Overview of VMSAv8-64 address translation using the 64KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 64KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR.TxSZ field. When using the 64KB translation granule, Table D4-16 shows this requirement.

Table D4-16 TCR.TnSZ values and IA ranges when there is no concatenation of translation tables

<table>

D0.2.6 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64.

For the address translations that are controlled by an Exception level that is using AArch64:

- The TCR_EL1.{SH0, ORGN0, IRGN0, SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walk, for each of TTBR0_EL1 and TTBR1_EL1.

- For the Secure and Non-secure EL1&0 stage 1 translations, each of TTBR0_EL1 and TTBR1_EL1 contains an ASID field, and the TCR_EL1.A1 field selects which ASID to use.

For this translation table format, Overview of the VMSAv8-64 address translation stages on page D4-1743 summarizes the lookup levels, and Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats on page D4-1792 describes the translation table entries.

The following subsections describe the use of this translation table format:

- Translation granule size and associate block and page sizes on page D4-1753.
- Selection between TTBR0 and TTBR1 on page D4-1755.
- Concatenated translation tables for the initial stage 2 lookup on page D4-1756.
- Possible translation table registers programming errors on page D4-1757.
Translation granule size and associate block and page sizes

Table D4-19 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. For completeness, this table includes information for AArch32 state. In the table, the OA bit ranges are the OA bits that the translation table descriptor specifies to address the block or page of memory, in an implementation that supports a 48-bit OA range.

Table D4-19 Translation table granule sizes, with block and page sizes, and output address ranges

<table>
<thead>

<tr>
<td></td>
<td>Three</td>
<td>-</td>
<td>64KB, OA[47:16]</td>
</tr>
</tbody>
</table>

Bit[1] of a translation table descriptor identifies whether the descriptor is a block descriptor, and:
- The 4KB granule size supports block descriptors only in level 1 and level 2 translation tables.
- The 16KB and 64KB granule sizes support block descriptors only in level 2 translation tables.

Setting bit[1] of a descriptor to 0 in a translation table that does not support block descriptors gives a Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for each lookup level and when accessing a single translation table:
- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the translation table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D4-20 shows this information for the 4KB translation granule size, Table D4-21 on page D4-1754 shows this information for the 16KB translation granule size, and Table D4-22 on page D4-1754 shows this information for the 64KB translation granule size.

Table D4-20 Properties of the address lookup levels, 4KB granule size

<table>
<thead>
<tr>
<th>Level</th>
<th>Maximum input address</th>
<th>Maximum output address</th>
<th>Number of entries</th>
<th>Block entries supported?</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Size</td>
<td>Address range</td>
<td>Address range</td>
<td>Size of addressed region</td>
</tr>
<tr>
<td>One</td>
<td>512GB</td>
<td>Address[38:30]</td>
<td>Address[47:30]</td>
<td>1GB</td>
</tr>
</tbody>
</table>
For the initial lookup level:

- If the IA range specified by the TCR.TxSZ field is smaller than the maximum size shown in these tables, this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.

- For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information see the stage 2 translation overviews in Overview of the VMSA8-64 address translation stages on page D4-1743 and Concatenated translation tables for the initial stage 2 lookup on page D4-1756.

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

### Table D4-20 Properties of the address lookup levels, 4KB granule size (continued)

<table>
<thead>
<tr>

<td>Three</td>
<td>512MB</td>
<td>Address[28:16]</td>
<td>Address[47:16]</td>
<td>64KB</td>
<td>8192 Page only</td>
</tr>
</tbody>
</table>

<sup>a</sup> That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

<sup>b</sup> The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.
Larger translation granule sizes typically requires fewer levels of translation tables to translate a particular size of virtual address.

For the TCR programming requirements for the initial lookup, see "Overview of the VMSAv8-64 address translation stages" on page D4-1743.

Selection between TTBR0 and TTBR1

Every translation table walk starts by accessing the translation table addressed by the TTBR for the stage 1 translation for the required translation regime.

For the EL1&0 translation regime, the VA range is split into two subranges as shown in Figure D4-14, and:

- TTBR0_EL1 points to the initial translation table for the lower VA subrange, that starts at address 0x0000_0000_0000_0000,
- TTBR1_EL1 points to the initial translation table for the upper VA subrange, that runs up to address 0xFFFF_FFFF_FFFF_FFFF.

Which TTBR is used depends only on the VA presented for translation:

- If the top bits of the VA are zero, then TTBR0_EL1 is used.
- If the top bits of the VA are one, then TTBR1_EL1 is used.

It is configurable whether this determination depends on the values of VA[63:56] or on the values of VA[55:48], see "Address tagging in AArch64 state" on page D4-1726.

Note

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the TCR_EL1.TnSZ values and the region for which an access generates a Translation fault is wider than shown in Figure D4-14. That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. Possible translation table registers programming errors on page D4-1757 describes this possibility.

Example D4-3 on page D4-1756 shows a typical application of this VA split.
Example D4-3 Example use of the split VA range, and the TTBR0_EL1 and TTBR1_EL1 controls

An example of using the split VA range is:

**TTBR0_EL1** Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- TTBR0_EL1 is updated to point to the level 1 translation table for the new context
- TCR_EL1 is updated if this change changes the size of the translation table
- CONTEXTIDR_EL1 is updated.

**TTBR1_EL1** Used for operating system and I/O addresses, that do not change on a context switch.

For each VA subrange, the input address size is $2^{(64-T_nSZ)}$, where $T_nSZ$ is one of TCR_EL1.{T0SZ, T1SZ},

This means the two VA subranges are:

**Lower VA subrange** $0x0000_0000_0000_0000$ to $(2^{(64-T0SZ)} - 1)$.

**Upper VA subrange** $(2^{64} - 2^{(64-T1SZ)})$ to $0xFFFF_FFFF_FFFF_FFFF$.

The minimum $T_nSZ$ value is 16, corresponding to the maximum input address range of 48 bits. **Example D4-4** shows the two VA subranges when T0SZ and T1SZ are both set to this minimum value.

**Example D4-4 Maximum VA ranges for EL1&0 stage 1 translations**

The maximum VA subranges correspond to T0SZ and T1SZ each having the minimum value of 16. In this case the subranges are:

**Lower VA subrange** $0x0000_0000_0000_0000$ to $0x0000_FFFF_FFFF_FFFF$.

**Upper VA subrange** $0xFFFF_0000_0000_0000$ to $0xFFFF_FFFF_FFFF_FFFF$.

Figure D4-14 on page D4-1755 indicates the effect of varying the $T_nSZ$ values.

As described in *Overview of the VMSAv8-64 address translation stages on page D4-1743*, the $T_nSZ$ values also determine the initial lookup level for the translation.

**Concatenated translation tables for the initial stage 2 lookup**

*Overview of the VMSAv8-64 address translation stages on page D4-1743* introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

Where a stage 2 translation would require 16 entries or fewer in its top-level translation table, the system designer can instead:

- Require the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- Start the translation at that next translation level.

In addition, when using the 16KB translation granule and requiring a 48-bit input address size for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

--- **Note** ---

This translation scheme:

- Avoids the overhead of an additional level of translation.
• Requires the software that is defining the translation to:
  — Define the concatenated translation tables with the required overall alignment.
  — Program VTTBR_EL2 to hold the address of the first of the concatenated translation tables.
  — Program VTCR_EL2 to indicate the required input address range and initial lookup level.

Concatenating additional translation tables at the initial level of lookup resolves additional address bits at that level. To resolve \( n \) additional address bits requires \( 2^n \) concatenated translation tables. Example D4-5 shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

**Example D4-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule**

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits [38:30]. To add three more address bits requires \( 2^3 \) translation tables, that is, eight translation tables. This means:

• The total size of the concatenated translation tables is \( 8 \times 4\text{KB} = 32\text{KB} \).
• This block of concatenated translation tables must be aligned to 32KB.
• The address range resolved at this lookup level is \( A[41:30] \), of which:
  — Bits \( A[41:39] \) select the 4KB translation table.
  — Bits \( A[38:30] \) index a descriptor within that translation table.

As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, Table D4-23 shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required IPA range means lookup starts at level 1 with a single translation table at that level.

**Table D4-23 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule**

<table>
<thead>
<tr>
<th>Configured stage 2 IA size</th>
<th>Lookup starts at level 0</th>
<th>Lookup starts at level 1</th>

<tr>
<td>IPA[42:0]</td>
<td>2(^{40}) bytes</td>
<td>16</td>
</tr>
</tbody>
</table>

\(^a\) Required alignment of the set of concatenated level 2 tables.

**Note**

Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are IPAs.

*Overview of the VMSAv8-64 address translation stages on page D4-1743* identifies all of the possible uses of concatenation. In all cases, the block of concatenated translation tables must be aligned to the block size.

**Possible translation table registers programming errors**

For a stage 2 translation, the programming of the VTCR_EL2.\( \{T0SZ, SL0\} \) fields must be consistent, see *Overview of the VMSAv8-64 address translation stages on page D4-1743*. 
Where the contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the TCR.TxSZ field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the TCR.TxSZ field.

- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the TCR.TxSZ field, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

The contiguous bit must apply:

- When using the 4KB translation granule, to 16 adjacent translation table entries, aligned so that the upper five bits of the input address range required to index the table entries are all the same.

- When using the 16KB translation granule, to:
  - 128 adjacent translation table entries, aligned so that the upper four bits of the input address range required to index the table entries are all the same, for entries in a level 3 translation table.
  - 32 adjacent translation table entries, aligned so that the upper six bits of the input address range required to index the table entries are all the same, for entries in a level 2 translation table.

- When using the 64KB translation granule, to 32 adjacent translation table entries, aligned so that the upper eight bits of the input address range required to index the table entries are all the same.

For more information about the contiguous bit see The Contiguous bit on page D4-1811.

**D4.2.7 The algorithm for finding the translation table entries**

This subsection gives the algorithms for finding the translation table entry that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- Finding the translation table entry when using the 4KB translation granule on page D4-1759.
- Finding the translation table entry when using the 16KB translation granule on page D4-1760.
- Finding the translation table descriptor when using the 64KB translation granule on page D4-1761.

Each subsection uses the following terms:

**BaseAddress** The base address for the level of lookup, as defined by:

- For the initial lookup level, the appropriate TTBR.
- Otherwise, the translation table address returned by the previous level of lookup.

**PAMax** The supported PA width, in bits.

**IA** The supplied IA for this stage of translation.

**TxSZ** The translation table size for this stage of translation:

- For EL1&0 stage 1 TCR_EL1.T0SZ or TCR_EL1.T1SZ, as appropriate.
- For EL1&0 stage 2 VTCR_EL2.T0SZ.
- For EL2 stage 1 TCR_EL2.T0SZ.
- For EL3 stage 1 TCR_EL3.T0SZ.

**SL0** VTCR_EL2.SL0. Applies to the Non-secure EL1&0 stage 2 translation only.
These subsections show only architecturally-valid programming of the TCR. See also Possible translation table registers programming errors on page D4-1757.

Finding the translation table entry when using the 4KB translation granule

Table D4-24 shows the translation table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of The algorithm for finding the translation table entries on page D4-1758 for more information about terms used in the table.

Identification support for the 4KB granule

The ID_AA64MMFR0_EL1.4Kgranule identifies whether an implementation supports the 4KB translation granule, as follows:

- **0b0000** 4KB granule size supported.
- **0b1111** 4KB granule size not supported.
Finding the translation table entry when using the 16KB translation granule

Table D4-25 shows the translation table descriptor address, for each level of lookup, when using the 16KB translation granule. See the start of The algorithm for finding the translation table entries on page D4-1758 for more information about terms used in the table.

c. This is the case where this level of lookup is not the initial level of lookup.

Identifying support for the 64KB granule

The ID_AA64MMFR0_EL1.64Kgranule identifies whether an implementation supports the 64KB translation granule, as follows:

- 0b0000 64KB granule size supported.
- 0b1111 64KB granule size not supported.

D4.2.8 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- Behavior when stage 1 address translation is disabled.
- Behavior when stage 2 address translation is disabled on page D4-1762.
- Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1763.

Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

Non-secure EL1 and EL0 accesses if the HCR_EL2.DC bit is set to 1

For the Non-secure EL1&0 translation regime, when the value of HCR_EL2.DC is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Write-Allocate, Outer Write-Back Read-Write-Allocate memory attributes.

--- Note ---

This applies for both instruction and data accesses.
All other accesses

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the SCTLR.I bit for the translation regime, as follows:

When the value of I is 0

The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

When the value of I is 1

The stage 1 translation assigns the Cacheable, Inner Write-Through no Write-Allocate Read-Allocate, Outer Write-Through no Write-Allocate Read Allocate Outer Shareable attribute.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults can be generated for this stage of address translation.

Note

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a Non-secure EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of HCR_EL2.DC is 1, in Non-secure state:

- The SCTLR_EL1.M bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means Non-secure EL1&0 stage 1 address translation is disabled.
- The HCR_EL2.VM bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that Non-secure EL1&0 stage 2 address translation is enabled.

See also Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1763.

Effect of disabling address translation on maintenance and address translation instruction instructions

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of HCR_EL2.DC affect some address translation instructions, see Address translation instructions, AT* on page D4-1776.

Behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA.
- The memory attributes and permissions from the stage 1 translation apply to the PA.

When both stages of address translation are disabled, see also Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1763.
Behavior of instruction fetches when all associated stages of translation are disabled

When EL3 is using AArch64, this section applies to:

• The Secure EL1&0 translation regime when Secure EL1&0 stage 1 address translation is disabled.
• The Secure EL3 translation regime, when Secure EL3 stage 1 address translation is disabled.
• The Non-secure EL2 translation regime, when Non-secure EL2 stage 1 address translation is disabled.
• The Non-secure EL1&0 translation regime, when both stages of address translation are disabled.

Note

• The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
• When the value of HCR_EL2.DC is 1, then the behavior of the Non-secure EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in Behavior when stage 1 address translation is disabled on page D4-1761.

In these cases, a memory location might be accessed as a result of an instruction fetch if the following condition is met:

• The memory location is in the same block of memory as, or in the next contiguous block of memory to, an instruction that a simple sequential execution of the program either requires to be fetched now or has required to be fetched since any of:
  — The last reset.
  — The last synchronization of instruction cache maintenance targeting the address of the instruction.
  — When executing in AArch32 state, the last synchronization of branch predictor maintenance targeting the address of the instruction.

In this description, the blocks of memory referred to are of the size of the minimum implemented translation granule and are aligned to that size.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

Note

To ensure architectural compliance, software must ensure that both of the following apply:

• Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
• Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.

D4.2.9 The implemented Exception levels and the resulting translation stages and regimes

Elsewhere, this chapter describes an implementation that includes all Exception levels, and describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:

• If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
• If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.
Figure D4-2 on page D4-1729 shows the set of translation regimes for an implementation that implements all of the Exception levels. Table D4-27 shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the Execution state being used by the highest implemented Exception level.

D4.2.10 Pseudocode description of VMSAv8-64 address translation

The following subsections gives a pseudocode description of the translation table walk:
- Definitions required for address translation.
- Performing the full address translation.
- Stage 1 translation on page D4-1765.
- Stage 2 translation on page D4-1767.
- Translation table walk on page D4-1768.
- Support functions on page D4-1773.

Definitions required for address translation

In pseudocode, the result of a translation table lookup, in either Execution state, is returned in a TLBRecord structure.

```plaintext
type TLBRecord is (  
  Permissions  perms,         // '0' = Global, '1' = not Global  
  bit          nG,             // AArch32 only  
  bits(4)      domain,         // AArch32 only  
  boolean      contiguous,     // Contiguous bit from page table  
  integer      level,          // In AArch32 Short-descriptor format, indicates Section/Page  
  integer      blocksize,      // Describes size of memory translated in KBytes  
  AddressDescriptor addrdesc  
)
```

Memory data type definitions on page D3-1714 includes definitions of the Permissions and AddressDescriptor parameters.

Performing the full address translation

The function AArch64.FullTranslate() performs a full translation table walk. For any translation regime it performs a stage 1 translation for the supplied virtual address, and for the Non-secure EL1&0 translation regime it then performs a stage 2 translation of the returned address.

```plaintext
// AArch64.FullTranslate()  
// =======================  
// Perform both stage 1 and stage 2 translation walks for the current translation regime. The  
// function used by Address Translation operations is similar except it uses the translation  
// regime specified for the instruction.  
AddressDescriptor AArch64.FullTranslate(bits(64) vaddress, AccType acctype, boolean iswrite,  
...
When stage 1 translation is disabled, the function AArch64.TranslateAddressS1Off() sets the memory attributes.
// AArch64.TranslateAddressS1Off()
// ===============================
// Called for stage 1 translations when translation is disabled to supply a default translation.
// Note that there are additional constraints on instruction prefetching that are not described in 
// this pseudocode.

TLBRecord AArch64.TranslateAddressS1Off(bits(64) vaddress, AccType acctype, boolean iswrite)
    assert !ELUsingArch32(S1TranslationRegime());

end if;

result.addrdesc.memattrs.outer = result.addrdesc.memattrs.inner;

result.perms.ap = bits(3) UNKNOWN;
result.perms.xn = '0';
result.perms.pxn = '0';

result.nG = bit UNKNOWN;
result.contiguous = boolean UNKNOWN;
result.domain = bits(4) UNKNOWN;
result.level = integer UNKNOWN;
result.blocksize = integer UNKNOWN;
result.addrdesc.paddress.physicaladdress = vaddress<47:0>;
result.addrdesc.paddress.NS = if IsSecure() then '0' else '1';
result.addrdesc.fault = AArch64.NoFault();
Stage 2 translation

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address space, and must be mapped to a PA by a stage 2 translation. Function AArch64.SecondStageWalk() performs this translation, by calling the AArch64.SecondStageTranslate() function. When called from AArch64.SecondStageWalk(), the AArch64.SecondStageTranslate() function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section.

```c
// AArch64.SecondStageWalk()
// =========================
// Perform a stage 2 translation on a stage 1 translation page table walk access.
AddressDescriptor AArch64.SecondStageWalk(AddressDescriptor S1, bits(64) vaddress, AccType acctype, integer size)
assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
iswrite = FALSE;
s2fs1walk = TRUE;
wasaligned = TRUE;
return AArch64.SecondStageTranslate(S1, vaddress, acctype, iswrite, wasaligned, s2fs1walk, size);
```

The AArch64.SecondStageTranslate() function performs the stage 2 address translation.

```c
// AArch64.SecondStageTranslate()
// ==============================
// Perform a stage 2 translation walk. The function used by Address Translation operations is
// similar except it uses the translation regime specified for the instruction.
AddressDescriptor AArch64.SecondStageTranslate(AddressDescriptor S1, bits(64) vaddress, AccType acctype, boolean iswrite, boolean wasaligned, boolean s2fs1walk, integer size)
assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
s2_enabled = HCR_EL2.VM == '1';
secondstage = TRUE;
if s2_enabled then                        // Second stage enabled
ipaddress = S1.paddress.physicaladdress<47:0>;
S2 = AArch64.TranslationTableWalk(ipaddress, vaddress, acctype, iswrite, secondstage, s2fs1walk, size);
// Check for unaligned data accesses to Device memory
if (!wasaligned && !IsFault(S2.addrdesc) && S2.addrdesc.memattrs.type == MemType_Device &&
acctype != AccType_IFETCH) then
S2.addrdesc.fault = AArch64.AlignmentFault(acctype, iswrite, secondstage);
if !IsFault(S2.addrdesc) then
S2.addrdesc.fault = AArch64.CheckS2Permission(S2.perms, vaddress, ipaddress, S2.level, acctype, iswrite, s2fs1walk);
// Check for instruction fetches from Device memory not marked as execute-never. As there
// has not been a Permission Fault then the memory is not marked execute-never.
if (!IsFault(S2.addrdesc) && S2.addrdesc.memattrs.type == MemType_Device &&
acctype == AccType_IFETCH) then
S2.addrdesc = AArch64.InstructionDevice(S2.addrdesc, vaddress, ipaddress, S2.level, acctype, iswrite, secondstage, s2fs1walk);
// Check for protected table walk
if (s2fs1walk && !IsFault(S2.addrdesc) && HCR_EL2.PTW == '1' &&
S2.addrdesc.memattrs.type == MemType_Device) then
```
Translation table walk

The function AArch64.TranslationTableWalk() returns the result, in the form of a TLBRecord, of a translation table walk made for a memory access from an Exception level that is using AArch64.

// AArch64.TranslationTableWalk()
// ==============================
// Returns a result of a translation table walk
//
// Implementations might cache information from memory in any number of non-coherent TLB caching structures, and so avoid memory accesses that have been expressed in this pseudocode. The use of such TLBs is not expressed in this pseudocode.

TLBRecord AArch64.TranslationTableWalk(bits(48) ipaddress, bits(64) vaddress, AccType acctype, boolean iswrite, boolean secondstage, boolean s2fs1walk, integer size)
if !secondstage then
    assert !ELUsingAArch32(S1TranslationRegime());
else

Support functions
In the translation table walk functions, the WalkAttrDecode() function determines the attributes for a translation table lookup.

// WalkAttrDecode()
// ================
MemoryAttributes WalkAttrDecode(bits(2) SH, bits(2) ORGN, bits(2) IRGN)
  MemoryAttributes memattrs;
  AccType acctype = AccType_NORMAL;
  memattrs.type = MemType_Normal;
The function `AArch64.S1AttrDecode()` decodes the attributes from a stage 1 translation table lookup.

```c
// AArch64.S1AttrDecode()
// =====================
// Converts the Stage 1 attribute fields, using the MAIR, to orthogonal
// attributes and hints.

MemoryAttributes AArch64.S1AttrDecode(bits<2> SH, bits<3> attr, AccType acctype)

MemoryAttributes memattrs;

mair = MAIR[];
index = 8 * UInt(attr);
attrfield = mair<index+7:index>;

if ((attrfield<7:4> != '0000' && attrfield<3:0> == '0000') ||
    (attrfield<7:4> == '0000' && attrfield<3:0> != 'xx00')) then
    // Reserved, maps to an allocated value
    (-, attrfield) = ConstrainUnpredictableBits();

if attrfield<7:4> == '0000' then            // Device
    memattrs.type = MemType_Device;
    memattrs.inner = MemAttrHints UNKNOWN;
    memattrs.outer = MemAttrHints UNKNOWN;
    memattrs.shareable = TRUE;
    memattrs.outershareable = TRUE;
    case attrfield<3:0> of
        when '0000'  memattrs.device = DeviceType_nGnRnE;
        when '0100'  memattrs.device = DeviceType_nGnRE;
        when '1000'  memattrs.device = DeviceType_nGRE;
        when '1100'  memattrs.device = DeviceType_GRE;
        otherwise    Unreachable();         // Reserved, handled above
    end case;

elsif attrfield<3:0> != '0000'  then        // Normal
    memattrs.type = MemType_Normal;
    memattrs.outer = LongConvertAttrsHints(attrfield<7:4>, acctype);
    memattrs.inner = LongConvertAttrsHints(attrfield<3:0>, acctype);
    memattrs.device = DeviceType UNKNOWN;
    memattrs.shareable = SH<1> == '1';
    memattrs.outershareable = SH == '10';

else
    Unreachable();                          // Reserved, handled above

return memattrs;
```

The function `AArch64.CheckPermission()` checks the access permissions returned by a stage 1 translation table lookup, see `Access permission checking` on page D3-1719.

The function `AArch64.CheckS2Permission()` checks the access permissions returned by a stage 2 translation table lookup.

```c
// AArch64.CheckS2Permission()
// ===========================
// Function used for permission checking from AArch64 stage 2 translations

FaultRecord AArch64.CheckS2Permission(Permissions perms, bits<64> vaddress, bits<48> ipaddress,
    integer level, AccType acctype, boolean iswrite, boolean s2fs1walk)

assert HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) && PSTATE.EL != EL2;
```
r = perms.ap<1> == '1';
w = perms.ap<2> == '1';
xn = perms.xn == '1';

// Stage 1 walk is checked as a read, regardless of the original type
if acctype == AccType_IFETCH && !s2fs1walk then
    fail = xn;
elsif iswrite && !s2fs1walk then
    fail = !w;
    failedread = FALSE;
else
    fail = !r;
    failedread = TRUE;

if fail then
    domain = bits(4) UNKNOWN;
    secondstage = TRUE;
    return AArch64.PermissionFault(ipaddress, level, acctype,
        !failedread, secondstage, s2fs1walk);
else
    return AArch64.NoFault();

The AddrTop() function returns the bit number of the most significant valid bit of a VA in the current translation
regime. If EL1 is using AArch64 and EL0 is using AArch32 then an address from EL0 is zero-extended to 64 bits.

integer AddrTop(bits(64) address);

D4.2.11 Address translation instructions

Each of the ARMv8 instruction sets provides instructions that return the result of translating an input address,
supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level
at which the instruction is executed. That is:

• No instruction executed in Non-secure state can return the result of a Secure address translation stage.

• No instruction can return the result of an address translation stage that is controlled by an Exception level
that is higher than the Exception level at which the instruction is executed.

Address translation instructions, AT* on page D4-1776 summarizes the A64 address translation instructions.

See also A64 system instructions for address translation on page C5-331.
Address translation instructions, AT*

The A64 assembly language syntax for address translation instructions is:

\[ \text{AT } \text{<operation>}, \text{<xt>} \]

Where:

<operation>. Is one of S1E1R, S1E1W, S1E0R, S1E0W, S12E1R, S12E1W, S12E0R, S12E0W, S1E2R, S1E2W, S1E3R, or S1E3W. <operation> has a structure of <stages><level><read|write>, where:

<stages>. Is one of:

- S1. Stage 1 translation.
- S12. Stage 1 translation followed by stage 2 translation.

<level>. Describes the Exception Level that the translation applies to. Is one of:

- E0. EL0.
- E1. EL1.
- E2. EL2.
- E3. EL3.

If <level> is higher than the current Exception Level the instruction is UNDEFINED.

<read|write> Is one of:

- R. Read.
- W. Write.

<xt>. The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

--- Note ---

If EL2 is not implemented but EL3 is implemented, the AT S12E* instructions are not UNDEFINED, but behave the same way as the equivalent AT S1E* instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

In each case, the address being translated is held in the 64-bit address argument register, Xt. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting PA is returned in PAR_EL1.PA, and PAR_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see Synchronous faults generated by address translation instructions on page D4-1777.

--- Note ---

The architecture provides a single PAR, PAR_EL1, that is used regardless of:

- The Exception level at which the instruction was executed.
- The Exception level that controls the stage or stages of translation used by the instruction.

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed. However, it is IMPLEMENTATION DEFINED whether the Address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

When Non-secure EL1&0 stage 1 address translation is disabled, any AT S1E0*, AT S1E1*, AT S12E0*, or ATS12E1* address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR_EL2.DC bit as described in Behavior when stage 1 address translation is disabled on page D4-1761.
Executing AT S1E2R or AT S1E2W at EL3 with SCR_EL3.NS==0 is UNDEFINED.

Note

AT S1E+ instructions at EL3 with SCR_EL3.NS==0 are not UNDEFINED but behave the same way as the equivalent AT S1E* instructions.

Synchronous faults generated by address translation instructions

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:

- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
- Synchronous external aborts during a translation table walk.

In addition:

- If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.
- For a stage 1 translation for the Non-secure EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see Stage 2 fault on a stage 1 translation table walk on page D4-1822.

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the PAR_EL1.FST field holds the fault status information. In these cases the PAR_EL1.PA field does not hold the output address of the translation.

The exceptions to this reporting the fault in PAR_EL1 are:

- Synchronous external aborts during a translation table walk are taken as a Data Abort exception.

For an address translation instruction executed at a particular Exception level, if the synchronous external abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

If the synchronous external abort is generated on a stage 2 translation table walk then:

- If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.
- If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

- The PAR_EL1 is UNKNOWN.
- The ESR_ELx of the target Exception Level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.
- The FAR_ELx of the target Exception Level holds the virtual address for the translation request.
For the AT S1E0* and AT S1E1* instructions executed from the Non-secure EL1 Exception level, if there is a synchronous stage 2 fault on a memory access made as part of the translation table walk then if the value of SCR_EL3.EA is 1 then a synchronous external abort on a stage 2 translation table walk is taken to EL3. In all other cases of a synchronous stage 2 fault on a memory access made as part of the translation table walk, the fault is taken as an exception to EL2, and:

- PAR_EL1 is UNKNOWN
- ESR_EL2 indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.
- HPFAR_EL2 holds the IPA that faulted
- FAR_EL2 holds the VA that the executing software supplied to the address translation instruction.

This fault can occur for any of the following reasons:

- Stage 2 Translation fault.
- Stage 2 Access fault.
- Stage 2 Permission fault.
- Stage 2 Address size fault.
- Synchronous external abort on a stage 2 translation table walk.

**Synchronization requirements of the address translation instructions**

Where an instruction results in an update to a system register, as is the case with the AT * address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the PAR_EL1.

**Note**

This is consistent with the AArch32 requirement, where the VA to PA translation instructions are expressed as CP15 register writes, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.
D4.3 Translation table walk examples

Figure D4-2 on page D4-1729 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. The VMSAv8-64 address translation system on page D4-1728 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System control registers relevant to MMU operation on page D4-1733 specifies the relevant registers, including the TCR and TTBR, or TTBRs, for each stage of address translation.

For any stage of translation, a TCR.TnSZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is 2^(64-TnSZ).

This section describes:

• Performing the initial lookup, for an address for which the initial lookup is either:
  — At the highest lookup level used for the appropriate translation granule size.
  — Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

  — The IA size is smaller than the largest size for the translation level, see Reduced IA width on page D4-1739.
  — For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see Concatenated translation tables on page D4-1740.

For examples of performing the initial lookup, see Examples of performing the initial lookup.

• The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see Full translation flows for VMSAv8-64 address translation on page D4-1785.

D4.3.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

• Performing the initial lookup using the 4KB translation granule.
• Performing the initial lookup using the 16KB granule on page D4-1781.
• Performing the initial lookup using the 64KB translation granule on page D4-1783.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Table D4-11 on page D4-1745 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D4-1728.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-11 on page D4-1745 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

• Initial lookup at level 0, 4KB translation granule on page D4-1780.
• Initial lookup at level 1, 4KB translation granule on page D4-1780.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Overview of stage 2 translations, 4KB granule on page D4-1744.
Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As Table D4-11 on page D4-1745 shows, a stage 1 or stage 2 initial lookup at level 0 is required when \(39 \leq n \leq 47\). For these lookups:

- \(TTBR[47:(n-35)]\) specify the translation table base address.
- \(\text{Bits}[n:39]\) of the input address are \(\text{bits}[(n-36):3]\) of the descriptor offset in the translation table.

--- Note ---

This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the TTBR are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- \(TTBR\) \(\text{bits}[47:10]\) specify the translation table base address.
- \(\text{Input address bit}[45:39]\) specify \(\text{bits}[9:3]\) of the descriptor offset.

Figure D4-15 shows this lookup.

![Figure D4-15 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0](image)

Supported input address range is \(IA[n:0], 4 \leq x \leq 12, n = x + 35\). When \(n\) is 47 the field marked ‡ is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Initial lookup at level 1, 4KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\).

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-11 on page D4-1745 shows, this applies to \(IA[n:0]\), where \(30 \leq n \leq 38\). For these lookups:

- There is a single translation table at this level.
- \(TTBR[47:(n-26)]\) specify the translation table base address.
- \(\text{Bits}[n:30]\) of the input address are \(\text{bits}[(n-27):3]\) of the descriptor offset in the translation table.

Figure D4-16 on page D4-1781 shows this lookup.
For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-11 on page D4-1745 shows, this applies to IA[$n$:0], where $39 \leq n \leq 42$. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)} \times 4$KB. This means TTBR[($n-27$):12] must be zero.
- TTBR[$47: (n-26)$] specify the base address of the block of concatenated translation tables.
- Bits[$n$:30] of the input address are bits[$(n-27):3$] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure D4-17 shows this lookup.

Supported input address range is IA[$n$:0], $4 \leq x \leq 12$, $n = x + 26$.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure D4-17 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D4-14 on page D4-1748 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D4-1728.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-14 on page D4-1748 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.
The following subsections describe these examples of the initial lookup:

- **Initial lookup at level 0, 16KB translation granule.**
- **Initial lookup at level 1, 16KB translation granule.**

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 16KB granule* on page D4-1747.

**Initial lookup at level 0, 16KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As Table D4-13 on page D4-1746 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, \(IA[47:0]\). For this lookup:

- The required translation table has only two entries, meaning its size is 16 bytes, and it must be aligned to 16 bytes.

Figure D4-18 shows this lookup.

**Initial lookup at level 1, 16KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables:

As Table D4-14 on page D4-1748 shows, this applies to \(IA[n:0]\), where \(36 \leq n \leq 46\). For these lookups:

- There is a single translation table at this level.
- TTBR[47:(n-32)] specify the translation table base address.
- Bits[n:36] of the input address are bits[(n-33):3] of the descriptor offset in the translation table.

Figure D4-19 on page D4-1783 shows this lookup.
D4 The AArch64 Virtual Memory System Architecture

D4.3 Translation table walk examples

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-14 on page D4-1748 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2×16KB. This means TTBR[14] must be zero.
- TTBR[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure D4-20 shows this lookup.

For stage 2 translations, the same principles apply to an initial lookup that Table D4-17 on page D4-1751 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

Figure D4-19 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D4-17 on page D4-1751 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D4-1728.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-17 on page D4-1751 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.
The following subsections describe these examples of the initial lookup:

- Initial lookup at level 1, 64KB translation granule.
- Initial lookup at level 2, 64KB translation granule.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Overview of stage 2 translations, 64KB granule on page D4-1751.

**Initial lookup at level 1, 64KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is IA\([n:0]\). As Table D4-17 on page D4-1751 shows, a stage 1 or stage 2 initial lookup at level 1 is required when \(42 \leq n \leq 47\). For these lookups:

- The size of the translation table is \(2^{(n-39)}\) bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits\([n:42]\) of the input address are bits\([(n-39):3]\) of the descriptor offset in the translation table.
- Bits\([47:(n-38)]\) of the TTBR specify the translation table base address.

Figure D4-21 shows this lookup.

```
\[
\begin{array}{cccccc}
47 & 42 & 41 & \ldots & n+1 & n \\
\hline
43 & 42 & 41 & \ldots & n+1 & n \\
\hline
\vdots
\end{array}
\]
```

Supported input address range is IA\([n:0]\), \(42 \leq n \leq 47\), \(x = n-38\). When \(n = 47\) the field marked ‡ is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure D4-21 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1**

**Initial lookup at level 2, 64KB translation granule**

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is IA\([n:0]\).

For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D4-17 on page D4-1751 shows, this applies to IA\([n:0]\), where \(29 \leq n \leq 41\). For these lookups:

- There is a single translation table at this level.
- TTBR\([47:(n-25)]\) of the specify the translation table base address.
- Bits\([n:29]\) of the input address are bits\([(n-26):3]\) of the descriptor offset in the translation table.

Figure D4-22 on page D4-1785 shows this lookup.
D4 The AArch64 Virtual Memory System Architecture
D4.3 Translation table walk examples

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D4-17 on page D4-1751 shows, this applies to IA[n:0], where 42 ≤ n ≤ 45. For these lookups:

• There are 2(m-41) concatenated translation tables at this level.
• These concatenated translation tables must be aligned to 2(m-41)×64KB. This means TTBR[(n-26):16] must be zero.
• TTBR[47:(n-25)] specify the base address of the block of translation tables.
• Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure D4-23 shows this lookup.

Supported input address range is IA[n:0]. 4 ≤ x ≤ 16, n = x + 25.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure D4-23 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

D4.3.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

• The table descriptor read in the previous lookup.
• The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The described flows:

• Resolve the maximum-sized IA range supported by the initial lookup level.
• Do not have any concatenation of translation tables.

Examples of performing the initial lookup on page D4-1779 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note
Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:
• The address and properties fields shown in the translation flows.
• Full translation flow using the 4KB granule and starting at level 0 on page D4-1787.
• Full translation flow using the 4KB granule and starting at level 1 on page D4-1788.
• Full translation flow using the 64KB granule and starting at level 1 on page D4-1789.
• Full translation flow using the 64KB granule and starting at level 2 on page D4-1790.

The address and properties fields shown in the translation flows

For the Non-secure EL1&0 stage 1 translation:
• Any descriptor address is the IPA of the required descriptor.
• The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1795.
Full translation flow using the 4KB granule and starting at level 0

Figure D4-24 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see The address and properties fields shown in the translation flows on page D4-1786.

For details of Properties fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure D4-24 Complete stage 1 translation of a 48-bit address using the 4KB translation granule
If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure D4-24 on page D4-1787 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

**Full translation flow using the 4KB granule and starting at level 1**

Figure D4-25 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see The address and properties fields shown in the translation flows on page D4-1786.

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

---

*Field has additional properties to the default RES0 definition, see the register description for more information.*
Figure D4-25 on page D4-1788 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure D4-24 on page D4-1787, shows how the translation for the 42-bit address start the same lookup process one stage later.

**Full translation flow using the 64KB granule and starting at level 1**

Figure D4-24 on page D4-1787 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows on page D4-1786*.

---

For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure D4-26 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.
The level 1 lookup resolves only 6 bits of the input address. As described in _Performing the initial lookup using the 64KB translation granule_ on page D4-1783, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR is extended, at the low-order end, to be bits[47:9].

### Full translation flow using the 64KB granule and starting at level 2

_Figure D4-25 on page D4-1788_ shows the complete translation flow for a level 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see _The address and properties fields shown in the translation flows_ on page D4-1786.

_Figure D4-27 Complete stage 1 translation of a 42-bit address using the 64KB translation granule_

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

_Figure D4-27_ shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in _Figure D4-26_ on page D4-1789, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR is bits[47:16].
D4.4 VMSAv8-64 translation table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the ARMv8 translation table descriptor formats:

- VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats.
- ARMv8 translation table level 3 descriptor formats on page D4-1794.

Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1795 then gives more information about the descriptor attribute fields, and Control of Secure or Non-secure memory access on page D4-1798 describe how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

D4.4.1 VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats

In the VMSAv8-64 translation table format, the difference in the formats of the level 0, level 1 and level 2 descriptors is:

- Whether a block entry is permitted.
- If a block entry is permitted, the size of the memory region described by that entry.

These differences depend on the translation granule, as follows:

4KB granule  A level 0 descriptor does not support block translation.

A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

16KB granule Level 0 and level 1 descriptors do not support block translation.

A block entry in a level 2 table describes the mapping of the associated 32MB input address range.

64KB granule Level 0 lookup is not supported.

A level 1 descriptor does not support block translation.

A block entry in a level 2 table describes the mapping of the associated 512MB input address range.

Figure D4-28 on page D4-1792 shows the ARMv8 level 0, level 1, and level 2 descriptor formats:
 Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Block: The descriptor gives the base address of a block of memory, and the attributes for that memory region.

1, Table: The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

**Block descriptor**

Gives the base address and attributes of a block of memory, as follows:

4KB translation granule

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 descriptor, bits[47:21] are bits[47:21] of the output address. This output address specifies a 2MB block of memory.

16KB translation granule

For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address. This output address specifies a 32MB block of memory.

64KB translation granule

For a level 2 Block descriptor, bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.

Bits[63:52, 11:2] provide attributes for the target memory block, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1795. The position and contents of these bits are identical in the level 2 block descriptor and in the level 3 page descriptor.
Table descriptor

Gives the translation table address for the next-level lookup, as follows:

**4KB translation granularity**

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[11:0] of the table address are zero.

**16KB translation granularity**

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[13:0] of the table address are zero.

**64KB translation granularity**

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1795.

If the translation table defines the Non-secure EL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.
D4 The AArch64 Virtual Memory System Architecture
D4.4 VMSAv8-64 translation table format descriptors

D4.4.2 ARMv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

Figure D4-29 shows the ARMv8 level 3 descriptor formats.

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid
Behaves identically to encodings with bit[0] set to 0.
This encoding must not be used in level 3 translation tables.

1, Page
Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor
Gives the output address of a page of memory, as follows:

4KB translation granule
Bits[47:12] are bits[47:12] of the output address for a page of memory.

16KB translation granule

64KB translation granule
Bits[47:16] are bits[47:16] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1795.
Note

The position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 block descriptors.

For the Non-secure EL1&0 stage 1 translations, the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

D4.4.3 Memory attribute fields in the VMSAv8-64 translation table format descriptors

Memory region attributes on page D4-1808 describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:

Table descriptor

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 table descriptor, that define the attributes for the next lookup level, see Next-level attributes in stage 1 VMSAv8-64 Table descriptors.

Block and page descriptors

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-1796
- Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors on page D4-1797.

Next-level attributes in stage 1 VMSAv8-64 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:52] are ignored:

Next-level descriptor attributes, stage 1 only

<table>
<thead>
<tr>

<td>APTable</td>
<td>IGNORED</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

UXNTable or XNTable †

PXNTable

† UXNTable for the EL1&0 translation regime, XNTable for the other regimes.

These attributes are:

NSTable, bit[63]

For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see Hierarchical control of Secure or Non-secure memory accesses on page D4-1798.

For memory accesses from Non-secure state, this bit is RES0 and is ignored by the PE.

APTable, bits[62:61]

Access permissions limit for subsequent levels of lookup, see Hierarchical control of data access permissions on page D4-1802.

APTable[0] is RES0:

- In the EL2 translation regime.
- In the EL3 translation regime.
UXNTable or XNTable, bit[60]

UXN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching on page D4-1806.

This bit is called UXNTable in the EL1&0 translation regime, where it only determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted. In the other translation regimes the bit is called XNTable.

PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching on page D4-1806.

This bit is reserved, SBZ:

- In the EL2 translation regime.
- In the EL3 translation regime.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-5876. For more information about these fields see Other fields in the VMSAv8-64 translation table format descriptors on page D4-1811.

Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1 translation:

<table>
<thead>
<tr>
<th>Upper attributes</th>
<th>Lower attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 59 58 55 54 53 52</td>
<td>11 10 9 8 7 6 5 4 2</td>
</tr>
</tbody>
</table>

Reserve for software use

UXN or XN †

PXN

Contiguous

† UXN for the EL1&0 translation regime, XN for the other regimes.

For a stage 1 descriptor, the attributes are:

UXN or XN, bit[54]

The Execute-never bit. Determines whether the region is executable, see Access permissions for instruction execution on page D4-1803.

This bit is called UXN (Unprivileged execute never) in the EL1&0 translation regime, where it only determines whether execution at EL0 of instructions fetched from the region is permitted. In the other translation regimes the bit is called XN (Execute never).

PXN, bit[53]

The Privileged execute-never bit. Determines whether the region is executable at EL1, see Access permissions for instruction execution on page D4-1803.

This bit is RES0 in the EL2 and EL3 translation regimes.

Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see The Contiguous bit on page D4-1811.

The not global bit. Determines whether the TLB entry applies to all ASID values, or only to the current ASID value, see Global and process-specific translation table entries on page D4-1826.

Valid only to the EL1&0 translation regime. This bit is RES0 in all other translation regimes.

AF, bit[10]

The Access flag, see The Access flag on page D4-1807.
SH, bits[9:8]  Shareability field, see Memory region attributes on page D4-1808.

AP[2:1], bits[7:6]  
Data Access Permissions bits, see Memory access control on page D4-1800.

--- Note ---
The ARMv8 translation table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

---

AP[1] is RES1 in the Non-secure EL2 translation regime.

NS, bit[5]  Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see Control of Secure or Non-secure memory access on page D4-1798.

For memory accesses from Non-secure state, this bit is RES0 and is ignored by the PE.

AttrIndx[2:0], bits[4:2]  
Stage 1 memory attributes index field, for the MAIR_ELx, see Memory region type and attributes, for stage 1 translations on page D4-1808.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-5876. For more information about these fields see Other fields in the VMSAv8-64 translation table format descriptors on page D4-1811.

Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

Attribute fields for VMSAv8-64 stage 2 Block and Page descriptors

<table>
<thead>
<tr>
<th>Upper attributes</th>
<th>Lower attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>11</td>
</tr>
<tr>
<td>60</td>
<td>10</td>
</tr>
<tr>
<td>59</td>
<td>9</td>
</tr>
<tr>
<td>58</td>
<td>8</td>
</tr>
<tr>
<td>55, 54, 53, 52</td>
<td>7, 6, 5, 2</td>
</tr>
</tbody>
</table>

Reserved for use by a System MMU
Reserved for software use
Contiguous

For a stage 2 descriptor, the attributes are:

XN, bit[54]  The Execute-never bit. Determines whether the region is executable, see Access permissions for instruction execution on page D4-1803.

Contiguous, bit[52]  
A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see The Contiguous bit on page D4-1811.

SH, bits[9:8]  Shareability field, see The memory region attributes for stage 2 translations, EL1&0 translation regime on page D4-1809.

S2AP, bits[7:6]  
Stage 2 data Access Permissions bits, see The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-1802.
Note

In the original VMSA v7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2]

Stage 2 memory attributes, see The memory region attributes for stage 2 translations, EL1&0 translation regime on page D4-1809.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-5876. For more information about these fields see Other fields in the VMSA v8-64 translation table format descriptors on page D4-1811.

D4.4.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether the access is to Secure or Non-secure memory.
- Is ignored by:
  - Accesses from Non-secure state.
  - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSA v8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see Hierarchical control of Secure or Non-secure memory accesses.

The NS and NSTable bits are valid only for memory accesses from Secure state described by translation table descriptors that are fetched from Secure memory, and:

- In the translation table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for translation table descriptors that are fetched from Secure memory, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

\[
\text{NS} = 0 \quad \text{Access the Secure physical address space.}
\]

\[
\text{NS} = 1 \quad \text{Access the Non-secure physical address space.}
\]

For Non-secure translation regimes, and for translation table descriptors fetched from Non-secure memory, the corresponding bit is RES0 and is ignored by the PE. The access is made to Non-secure memory, regardless of the value of the bit.

Hierarchical control of Secure or Non-secure memory accesses

For VMSA v8-64 table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

\[
\text{NSTable} = 0 \quad \text{The defined table address is in the Secure physical address space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.}
\]

\[
\text{NSTable} = 1 \quad \text{The defined table address is in the Non-secure physical address space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:}
\]

\[
- \text{The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.}
\]

• The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if either:
• NSTable is set to 1.
• The fetch ignores the values of NS and NSTable, because of a higher-level fetch with NSTable set to 1.

That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see Global and process-specific translation table entries on page D4-1826.

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.
D4.5 Access controls and memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. Control of Secure or Non-secure memory access on page D4-1798 describes the address map control, and the following sections describe the other fields:

- Memory access control.
- Memory region attributes on page D4-1808.
- Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-1812.

Note

This section describes the access controls and memory region attributes for each of the translation regimes, and for both stages of translation in the Non-secure EL1&0 translation regime. In general, attribute assignment is simpler in the EL2 and EL3 translation regimes, and in these regimes behavior is consistent with fields in the translation tables being treated as follows:

- APTable[0] is RES0 and is ignored by the PE, meaning it is treated as if it is 0.
- AP[1] is RES1 and is ignored by the PE, meaning it is treated as if it is 1.
- The PXNTable bit is RES0 and is ignored by the PE, meaning it is treated as if it is 0.
- The PXN field is RES0 and is ignored by the PE, meaning it is treated as if it is 0.

D4.5.1 Memory access control

The access control fields in the translation table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- About the access permissions.
- The data access permission controls on page D4-1801.
- Access permissions for instruction execution on page D4-1803.
- The Access flag on page D4-1807.

About the access permissions

Note

This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 in Non-secure state can see only the access permissions defined by the Non-secure EL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the Non-secure software executing at EL1 or EL0.

The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see The AP[2-1] data access permissions, for stage 1 translations on page D4-1801.

Note

The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see The VMSAv8-32 Short-descriptor translation table format on page G4-4078. The VMSAv8-64 translation table format does not define an AP[0] bit.
• In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1802.

• Uses the UXN, XN and PXN bits to define access controls for instruction fetches, see *Access permissions for instruction execution* on page D4-1803.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

--- Note ---
In an implementation that includes EL2, each stage of the translation of a memory access made from Non-secure EL1 or EL0 has its own, independent, permission check.

The data access permission controls

The following subsubsections describe the data access permission controls:

• *The AP[2:1] data access permissions, for stage 1 translations.*

• *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1802.

• *Hierarchical control of data access permissions* on page D4-1802.

### The AP[2:1] data access permissions, for stage 1 translations

For the VMSA:8-64 EL1&0 translation regime, the AP[2:1] bits control the stage 1 data access permissions, and:

<table>
<thead>
<tr>
<th>AP[2]</th>
<th>Access from EL1</th>
<th>Access from EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Read/write</td>
<td>None</td>
</tr>
<tr>
<td>1</td>
<td>Read/write</td>
<td>Read/write</td>
</tr>
<tr>
<td>10</td>
<td>Read-only</td>
<td>None</td>
</tr>
<tr>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

For translation regimes other than the EL1&0 translation regimes, AP[2] determines the stage 1 data access permissions, and AP[1] is:

• SBO.

• Ignored by hardware and is treated as if it is 1.

Table D4-28 shows the effect of the data access permission bits for stage 1 of the EL1&0 translation regime. In this table, an entry of None indicates that any access from that Exception level faults.

### Table D4-28 Data access permissions for stage 1 of the EL1&0 translation regime

For the Non-secure EL1&0 translation regime:

• The stage 2 translation also defines data access permissions, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1802.

• When both stages of translation are enabled, *Combining the stage 1 and stage 2 data access permissions* on page D4-1813 describes how these permissions are combined.
Table D4-29 shows the effect of the AP[2] data access permission bit for the EL2 and EL3 translation regimes.

<table>
<thead>
<tr>
<th>AP[2]</th>
<th>Access from EL2 or EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Read/write</td>
</tr>
<tr>
<td>1</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

The S2AP data access permissions, Non-secure EL1&0 translation regime

In the Non-secure EL1&0 translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 translation table descriptors define the data access permissions as Table D4-30 shows. In this table, an entry of None indicates that any access generates a permission fault.

Table D4-30 Data access permissions for stage 2 of the Non-secure EL1&0 translation regime,

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access from Non-secure EL1 or Non-secure EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>None</td>
</tr>
<tr>
<td>01</td>
<td>Read-only</td>
</tr>
<tr>
<td>10</td>
<td>Write-only</td>
</tr>
<tr>
<td>11</td>
<td>Read/write</td>
</tr>
</tbody>
</table>

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see Combining the stage 1 and stage 2 data access permissions on page D4-1813.

Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-1812 gives more information about the use of the stage 1 and stage 2 access permissions in an implementation of virtualization.

Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

Note

Similar hierarchical controls apply to instruction fetching, see Hierarchical control of instruction fetching on page D4-1806.

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table D4-31 shows.

As stated in the table footnote, for the EL2 translation regime, APTable[0] is reserved, SBZ, and is ignored by the hardware.

Table D4-31 Effect of APTable[1:0] on subsequent levels of lookup

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01</td>
<td>Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
</tbody>
</table>
The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

### Access permissions for instruction execution

Execute-never (XN) controls determine whether instructions can be executed from a memory region. These controls are:

- **UXN, Unprivileged Execute never**
  - Defined only for stage 1 of the EL1&0 translation regime.

- **PXN, Privileged execute never**
  - Used only for stage 1 of the EL1&0 translation regime:
    - For the EL2 and EL3 translation regimes, the descriptors define a PXN bit that is reserved, SBZ, and is ignored by hardware.
    - For stage 2 of the Non-secure EL1&0 translation regime, the corresponding bit position is reserved, SBZ, and is ignored by hardware.

- **XN, Execute never**
  - Defined for stage 2 of the EL1&0 translation regime and for stage 1 of the EL2 and EL3 translation regimes.

Each of these bits is set to 1 to indicate that instructions cannot be executed from the target memory region. In addition:

- For the EL1&0 translation regime, if the value of the AP[2:1] bits is 0b01, permitting write access from EL0, then the PXN bit is treated as if it has the value 1, regardless of its actual value.

- For each translation regime, if the value of the corresponding SCTLR_ELx.WXN bit is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN bit. For more information see **Preventing execution from writable locations** on page D4-1806.

- The SCR_EL3.SIF bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see **Restriction on Secure instruction fetch** on page D4-1807.

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

---

**Note**

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.
Note

- Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.

- The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.

- When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1763 describes how disabling all stages of address translation affects instruction fetching.

The following subsubsections describe the data access permission controls:

- Instruction execution permissions for stage 1 translations.
- Instruction execution permissions for stage 2 translations on page D4-1805.
- Hierarchical control of instruction fetching on page D4-1806.
- Preventing execution from writable locations on page D4-1806.
- Restriction on Secure instruction fetch on page D4-1807.

Instruction execution permissions for stage 1 translations

Table D4-32 and Table D4-33 on page D4-1805 include the AP[2:1] read and write permissions shown in Table D4-28 on page D4-1801 and Table D4-29 on page D4-1802. These permissions are shown as:

- **R** Indicates Read permission granted.
- **W** Indicates Write permission granted.

Table D4-32 shows the access permissions for instruction execution for stage 1 of the EL1&0 translation regime.

a. SCTLR_EL2 for the EL2 translation regime, SCTLR_EL3 for the EL3 translation regime.
b. Not executable because of the SCTLR_ELx.WXN control, because region is writable at this Exception level.

Instruction execution permissions for stage 2 translations

For the Non-secure EL1&0 stage 2 translation, the XN bit in the stage 2 translation table descriptors controls the execution permission, and this control is completely independent of the S2AP access permissions.

Table D4-34 Access permissions for instruction execution for stage 2 of the Non-secure EL1&0 translation regime,

<table>
<thead>
<tr>
<th>XN</th>
<th>Access from Non-secure EL1 or Non-secure EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Executable</td>
</tr>
<tr>
<td>1</td>
<td>Not executable</td>
</tr>
</tbody>
</table>
The stage 2 XN access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined at stage 1 of the translation, see Combining the stage 1 and stage 2 instruction execution permissions on page D4-1813.

**Hierarchical control of instruction fetching**

The VMSA v8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

--- Note ---

Similar hierarchical controls apply to data accesses, see Hierarchical control of data access permissions on page D4-1802.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- UXNTable or XNTable restricts the XN control:
  - When the value of the XNTable bit is 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of the UXNTable bit is 1, the UXN bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of a UXNTable or XNTable bit is 0 the bit has no effect.

- For the EL1&0 translation regime, PXNTable restricts the PXN control:
  - When PXNTable is set to 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When PXNTable is set to 0 it has no effect.

--- Note ---

The UXNTable, XNTable, and PXNTable settings are combined with the UXN, XN, and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The UXNTable, XNTable, and PXNTable controls are provided only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of UXNTable, XNTable, or PXNTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to UXNTable, XNTable, or PXNTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

**Preventing execution from writable locations**

ARMv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as UXN, PXN, or XN, regardless of the value of the UXN, PXN, or XN bit:

- For the EL1&0 translation regime, when the value of SCTLR_EL1.WXN is 1:
  - All regions that are writable from EL0 at stage 1 of the address translation are treated as UXN.
  - All regions that are writable from EL1 at stage 1 of the address translation are treated as PXN

- For the EL2 translation regime, when the value of SCTLR_EL2.WXN is 1, all regions that are writable at stage 1 of the address translation are treated as XN.

- For the EL3 translation regime, when the value of SCTLR_EL3.WXN is 1, all regions that are writable at stage 1 of the address translation are treated as XN.
Note

- The SCTLR_ELx.WXN controls are intended to be used in systems with very high security requirements.
- Setting a WXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of a UXN, XN, or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these bits. This means that any change of these bits without a corresponding change of VMID might require synchronization and TLB invalidation, as described in TLB maintenance requirements and the TLB maintenance instructions on page D4-1828.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR_EL3.SIF. When the value of this bit is 1, and execution is using the EL3 translation regime or the Secure EL1 translation regime, any attempt to execute an instruction fetched from Non-secure physical memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in TLB maintenance requirements and the TLB maintenance instructions on page D4-1828.

The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0.

The AF bit in the translation table descriptors is the Access flag.

Software management of the Access flag

ARMv8 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

Note

If a system incorporates a System MMU that implements the ARM SMMUv3 architecture and software shares translation tables between the ARM PE and the SMMUv3, then the software must be aware of the possibility that the System MMU update the access flag in hardware.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.
D4.5.2 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields, that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, *Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-1812* describes how the assignments from the two stages are combined.

### Note

In a virtualization implementation, a hypervisor, executing at EL2, might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

The following sections describe these attributes:

- The memory region attributes for stage 1 translations.
- The memory region attributes for stage 2 translations, EL1&0 translation regime on page D4-1809.
- Other fields in the VMSAv8-64 translation table format descriptors on page D4-1811.

#### The memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

**Memory type and attributes**

These are described indirectly, by registers referenced by bits in the table descriptor. This is described as remapping the memory type and attribute description. *Memory region type and attributes, for stage 1 translations* describes this encoding.

**Shareability**

The SH[1:0] field in the translation table descriptor encodes shareability information. *Shareability for Normal memory, for stage 1 translations on page D4-1809* describes this encoding.

**Memory region type and attributes, for stage 1 translations**

In the VMSAv8-64 translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the MAIR_ELx that specifies the attributes for the corresponding memory region. The required field is Attrn, where \( n = \text{AttrIndx}[2:0] \). For more information about AttrIndx[2:0] see *Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-1796*.

### Note

Each MAIR_ELx is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the MAIR_ELx register descriptions for more information.

Each MAIR_ELx.Attrn field defines, for the corresponding memory region:

- The memory type, Device or Normal.
- For Device memory, the Device memory type, one of:
  - Device-nGnRnE.
  - Device-nGnRE.
  - Device-nGRE.
  - Device-GRE.
For Normal memory:

- The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back
- For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or Do not allocate, and the Transient allocation hints.

For more information about the memory type and attributes, see Memory types and attributes on page B2-93.

**Shareability for Normal memory, for stage 1 translations**

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-35 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

**Note**

The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

See Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-1815 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

**The memory region attributes for stage 2 translations, EL1&0 translation regime**

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- **Memory region type and attributes for stage 2 translations** on page D4-1810 describes how the MemAttr[3:0] field defines these attributes.
- The SH[1:0] field in the translation table descriptor encodes shareability information. **Shareability for Normal memory, for stage 2 translations** on page D4-1811 describes this encoding.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- **Combining the stage 1 and stage 2 memory type attributes** on page D4-1814.
- **Combining the stage 1 and stage 2 cacheability attributes for Normal memory** on page D4-1814.
- **Combining the stage 1 and stage 2 shareability attributes for Normal memory** on page D4-1815.
Memory region type and attributes for stage 2 translations

Table D4-36 shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the outer cacheability of a Normal memory region.

Table D4-36 VMSAv8-64 MemAttr[3:2] encoding, stage 2 translation

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Outer cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device. MemAttr[1:0] encodes the Device memory type.</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal. MemAttr[1:0] encodes the Inner Cacheability.</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>Outer Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td></td>
<td>Outer Write-Back Cacheable</td>
</tr>
</tbody>
</table>

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2]==0b00, indicating Device memory, Table D4-37 shows the encoding of MemAttr[1:0].

Table D4-37 MemAttr[1:0] encoding for Device memory

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>

- When MemAttr[3:2]!=0b00, indicating Normal memory, Table D4-38 shows the encoding of MemAttr[1:0].

Table D4-38 MemAttr[1:0] encoding for Normal memory

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Behavior is UNPREDICTABLE, see text</td>
</tr>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

When the value of MemAttr[3:2] is not 0b00, the value of 0b00 for MemAttr[1:0] is reserved and must not be used. If this value is used for MemAttr[1:0] when MemAttr[3:2] is not 0b00, then behavior is UNPREDICTABLE.

--- Note ---
The stage 2 translation does not assign any allocation hints.

--- Note ---
The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
- MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.
Shareability for Normal memory, for stage 2 translations

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-39 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

Note

- This encoding is the same as the shareability encoding described in Shareability for Normal memory, for stage 1 translations on page D4-1809.
- The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

See Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-1815 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

Other fields in the VMSAv8-64 translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors:
- The Contiguous bit.
- IGNORED fields on page D4-1812.
- Field reserved for software use on page D4-1812.

The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a contiguous output address range. The required number of adjacent entries depends on the current translation granule size, as follows:

4KB granule 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

16KB granule This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

Level 2 lookup The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.
**Level 3 lookup**  
The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

**64KB granule**  
32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the contiguous bit. Possible translation table registers programming errors on page D4-1757 describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

**IGNORED fields**

In the VMSAv8-64 translation table descriptors, the following fields are identified as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 table descriptors, bits[58:52].
- In the stage 1 and stage 2 block and page descriptors, bits[63:59] and bits[58:55].

Of these fields:

- In the stage 1 and stage 2 block and page descriptors, bits[58:55] are reserved for software use, see Field reserved for software use.
- In the stage 2 block and page descriptors, bits[63:60] are reserved for use by a System MMU control.

**Field reserved for software use**

The architecture reserves a 4-bit IGNORED field in the Block and Page table descriptors, bits[58:52], for software use. The definition of IGNORED means the architecture guarantees that hardware makes no use of this field.

--- **Note** ---

This means there is no need to invalidate the TLB if these bits are changed.

**D4.5.3 Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime**

The Non-secure EL1&0 translation regime comprises two stage of translation, each of which can be enabled independently:

- Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1. Stage 1 MMU faults are taken to EL1.
- When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
  - Affect only the Non-secure stage 1 access permissions settings.
— Take no account of whether the accesses are at EL1 or EL0.
— Permit software executing at EL2 to assign a write-only attribute to a memory region.
Stage 2 MMU faults are taken to EL2.

--- Note ---
In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:
- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

---

**Combining the stage 1 and stage 2 data access permissions**

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *The AP[2:1] data access permissions, for stage 1 translations* on page D4-1801.
- The stage 2 permissions described in *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1802.

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

**Combining the stage 1 and stage 2 instruction execution permissions**

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *Instruction execution permissions for stage 1 translations* on page D4-1804.
- The stage 2 permissions described in *Instruction execution permissions for stage 2 translations* on page D4-1805.

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.
Combining the stage 1 and stage 2 memory type attributes

Table D4-40 shows the rules for combining the stage 1 and stage 2 memory type assignments.

<table>
<thead>
<tr>
<th>Rule</th>
<th>If either stage of translation assigns:</th>
<th>The resultant memory type is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device has precedence over Normal</td>
<td>Any Device memory type</td>
<td>A Device memory type</td>
</tr>
<tr>
<td>Non-Gathering has precedence over Gathering</td>
<td>A Device-nGxx memory type</td>
<td>A Device-nGxx memory type</td>
</tr>
<tr>
<td>Non-Reordering has precedence over Reordering</td>
<td>A Device-nGnRx memory type</td>
<td>A Device-nGnRx memory type</td>
</tr>
<tr>
<td>No Early write acknowledge has precedence over Early write acknowledge</td>
<td>The Device-nGnRnE memory type</td>
<td>The Device-nGnRnE memory type</td>
</tr>
</tbody>
</table>

Regardless of any shareability attribute obtained as described in Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-1815:

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation see Combining the stage 1 and stage 2 cacheability attributes for Normal memory.

The combining of the memory type attributes from the two stages of translation means a translation table walk for stage 1 translation can be made to a type of Device memory. If this occurs then:

- If the value of HCR_EL2.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of HCR_EL2.PTW is 1, then the memory access generates a stage 2 Permission fault.

Combining the stage 1 and stage 2 cacheability attributes for Normal memory

For a Normal memory region, Table D4-41 shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes.

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>

<tr>
<td>Write-Through or Write-Back Cacheable</td>
<td>Write-Through Cacheable</td>
<td>Write-Through Cacheable</td>
</tr>
<tr>
<td>Write-Back Cacheable</td>
<td>Write-Back Cacheable</td>
<td>Write-Back Cacheable</td>
</tr>
</tbody>
</table>
Combining the stage 1 and stage 2 shareability attributes for Normal memory

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in Combining the stage 1 and stage 2 memory type attributes on page D4-1814, is any type of Device memory.

- The resultant memory type attribute, described in Combining the stage 1 and stage 2 memory type attributes on page D4-1814, is Normal memory, and the resultant cacheability, described in Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-1814, is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, Table D4-42 shows how the stage 1 and stage 2 shareability assignments are combined.

Table D4-42 Combining the stage 1 and stage 2 shareability assignments for Normal memory\(^a\)

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant shareability</th>
</tr>

<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>

\(^a\) Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.
**D4.6 MMU faults**

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

- **Debug exception**
  An exception caused by the debug configuration, see Chapter D2 AArch64 Self-hosted Debug.

- **Alignment fault**
  An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see Alignment support on page B2-77.

- **MMU fault**
  An MMU fault is a fault generated by the fault checking sequence for the current translation regime. The remainder of this section describes MMU faults.

- **External abort**
  Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called *aborts*.

MMU faults are synchronous exceptions that fall into two categories in AArch64:

- Data Aborts.
- Instruction Aborts

**Note**

The Instruction Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

External aborts can be reported synchronously or asynchronously. In AArch64 state, asynchronous external aborts are reported using the SError interrupt.

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Exception Syndrome Registers* (ESRs) to record context information.

For more information, see Synchronous exception types, routing and priorities on page D1-1545.

The Exception level that the MMU fault is taken to depends on the translation regime that generated the fault. The fault context saved in the appropriate ESR_ELx register, where ELx is the Exception level that the fault is taken to, is dependent on whether:

- The MMU fault is due to an Instruction or Data Abort.
- The exception is taken from the same or a lower Exception level.

Software stepping, a debug feature, and a misaligned PC exception are the only exceptions that are higher than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For details on the exception model priorities, see Synchronous exception prioritization on page D1-1546.

The following sections describe the abort mechanisms:

- Types of MMU faults on page D4-1817.
- The MMU fault-checking sequence on page D4-1819.
- Prioritization of synchronous aborts from a single stage of address translation on page D4-1822.
- Pseudocode description of the MMU faults on page D4-1824.
D4.6.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in The MMU fault-checking sequence on page D4-1819.

The following list includes all the types of exceptions that can occur:
- Alignment fault.
- Permission fault.
- Translation fault.
- Address size fault.
- Synchronous external abort on a translation table walk.
- Access flag fault.
- TLB conflict abort.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults:
- Permission fault.
- Translation fault on page D4-1818.
- Address size fault on page D4-1818.
- External abort on a translation table walk on page D4-1818.
- Access flag fault on page D4-1819.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See About the access permissions on page D4-1800 for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot generate Permission faults, except that:

- A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in Stage 2 fault on a stage 1 translation table walk on page D4-1822.
- When SCTLR_EL1.UCI is set to 1, enabling EL0 access for the DC CVAU, DC CVAC, DC CIVAC, and IC IVAU instructions, the use of these instructions at EL0 to a location without read permission at EL0 generates a Permission fault.
- A DC IVAC instruction requires write permission to the address it invalidates, otherwise it generates a Permission fault.

Note

- Execution of the DCIMVAC instruction in AArch32 state does not have this write permission requirement.
- When Non-secure EL1&0 stage 2 address translation is enabled, a DC IVAC instruction executed in Non-secure state operates as a DC CIVAC instruction, as described in Effects of virtualization and security on the cache maintenance instructions on page D3-1704.

The Data Cache Zero instruction, DC ZVA, operates as set of stores to each byte within the block being accessed, and therefore it generates a Permission fault if the translation system does not permit writes to these locations.
Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see VMSAv8-64 translation table format descriptors on page D4-1791.

In addition, a Translation fault is generated if the input address for a translation either does not map on to an address range of a Translation Table Base Register, or the Translation Table Base Register range that it maps on to is disabled. In these cases the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a Translation Table Base Register failed.

A data or unified cache maintenance by VA instruction can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Address size fault

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following has nonzero address bits above the output address size, for the current stage of translation:

- The TTBR used for the translation.
- A translation table entry.
- The output address of the translation.

For an Address size fault generated because the TTBR used for the translation has nonzero address bits above the output address size, the reported fault code indicates a fault at level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

A data or unified cache maintenance by VA instruction can generate an Address size fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For more information on Address size faults, see Output address size on page D4-1734.

External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using the SError interrupt exception.

Behavior of external aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in Address translation instructions, functional group on page G4-4241 require translation table walks. An external abort can occur in the translation table walk. This is reported as follows:

- If the external abort is synchronous, using a synchronous Data Abort exception.
- If the external abort is asynchronous, using the SError interrupt exception.

For more information, see Synchronous faults generated by address translation instructions on page D4-1777.
Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a translation table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see VMSAv8-64 translation table format descriptors on page D4-1791.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED. For more information, see The Access flag on page D4-1807.

D4.6.2 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults it generates an Instruction Abort.
- If an data memory access faults it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see About address translation on page D4-1731.

Note

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in TLB conflict aborts on page D4-1828.

Types of MMU faults on page D4-1817 describes the faults that an MMU fault-checking sequence can report.

Figure D4-30 on page D4-1820 shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Non-secure EL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.
Figure D4-30 Fetching the descriptor in a VMSAv8-64 translation table walk

Figure D4-31 on page D4-1821 shows the full VMSA fault checking sequence, including the alignment check on the initial access.
Figure D4-31 VMSAv8-64 fault checking sequence

- Is the access subject to an alignment check?
- Does the address map to a TTBR?
- Not permitted at the lowest lookup level
- Fault any unaligned access to Device memory

† Link to and from Fetching the descriptor flowchart
‡ See Fetching the descriptor flowchart

1. Is the access subject to an alignment check?
2. Does the address map to a TTBR?
3. Not permitted at the lowest lookup level
4. Fault any unaligned access to Device memory

† Link to and from Fetching the descriptor flowchart
‡ See Fetching the descriptor flowchart
Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If SCR_EL3.EA is set to 1, a synchronous external abort is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. ESR_EL2.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1520.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device attribute assigned on the stage 2 translation of the address accessed. When the HCR_EL2.PTW bit is set to 1, such an access generates a stage 2 Permission fault.

Note

On most systems, such a mapping to Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if HCR_EL2.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure EL1 or EL0 mode. For more information see Changing HCR_EL2.PTW on page D4-1840.

A cache maintenance instruction executed at Non-secure EL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

D4.6.3 Prioritization of synchronous aborts from a single stage of address translation

For a single stage of translation, the priority of the memory management faults on a memory access is as follows, ordered from highest priority to lowest priority. For memory accesses that undergo two stages of translation, the italic entries show where the faults from second stage translations can occur. A second stage fault within a second stage translation follows the same priority of faults:

1. Alignment fault not caused by memory type, possible for stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a TTBR that is disabled. This includes VTCR_EL2.TOSZ being inconsistent with VTCR_EL2.SL0.
3. Address size fault on a TTBR caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The physical address being out of the range implemented.
4. Second stage abort on a level 0 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.
5. Synchronous parity or ECC error on a level 0 lookup of a translation table walk.
6. Synchronous external abort on a level 0 lookup level of a translation table walk.
7. Translation fault on a level 0 translation table entry.
8. Address Size fault a level 0 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.
9. **Second stage abort on a level 1 lookup of a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.

10. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.

11. Synchronous external abort on a level 1 lookup level of a translation table walk.

12. Translation fault on a level 1 translation table entry.

13. Address size fault on a level 1 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

14. **Second stage abort on a level 2 lookup of a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.

15. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.

16. Synchronous external abort on a level 2 lookup level of a translation table walk.

17. Translation fault on a level 2 translation table entry.

18. Address size fault on a level 2 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

19. **Second stage abort on a level 3 lookup of a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.

20. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.

21. Synchronous external abort on a level 3 lookup level of a translation table walk.

22. Translation fault on a level 3 translation table entry.

23. Address size fault on a level 3 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

25. Alignment fault caused by the memory type.

26. Permission fault.

27. **A fault from the state 2 translation of the memory access.** When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented.

28. Synchronous parity or ECC error on the memory access.

29. Synchronous External Abort on the memory access.

--- **Note** ---

The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented.

The prioritization of IMPLEMENTATION DEFINED MMU faults for LDREX or STREX to unsupported memory types is IMPLEMENTATION DEFINED.
D4.6.4 Pseudocode description of the MMU faults

The following functions generate fault records that describe MMU faults.

```c
// AArch64.AccessFlagFault()
// =========================
FaultRecord AArch64.AccessFlagFault(bits(48) ipaddress, integer level,
    AccType acctype, boolean iswrite, boolean secondstage,
    boolean s2fs1walk)
    extflag = bit UNKNOWN;
    return AArch64.CreateFaultRecord(Fault_AccessFlag, ipaddress, level, acctype, iswrite,
    extflag, secondstage, s2fs1walk);

// AArch64.TranslationFault()
// ==========================
FaultRecord AArch64.TranslationFault(bits(48) ipaddress, integer level,
    AccType acctype, boolean iswrite, boolean secondstage,
    boolean s2fs1walk)
    extflag = bit UNKNOWN;
    return AArch64.CreateFaultRecord(Fault_Translation, ipaddress, level, acctype, iswrite,
    extflag, secondstage, s2fs1walk);

// AArch64.AddressSizeFault()
// ==========================
FaultRecord AArch64.AddressSizeFault(bits(48) ipaddress, integer level,
    AccType acctype, boolean iswrite, boolean secondstage,
    boolean s2fs1walk)
    extflag = bit UNKNOWN;
    return AArch64.CreateFaultRecord(Fault_AddressSize, ipaddress, level, acctype, iswrite,
    extflag, secondstage, s2fs1walk);

// AArch64.PermissionFault()
// =========================
FaultRecord AArch64.PermissionFault(bits(48) ipaddress, integer level,
    AccType acctype, boolean iswrite, boolean secondstage,
    boolean s2fs1walk)
    extflag = bit UNKNOWN;
    return AArch64.CreateFaultRecord(Fault_Permission, ipaddress, level, acctype, iswrite,
    extflag, secondstage, s2fs1walk);
```

Abort exceptions on page D3-1720 describes how fault records are used.
Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the need for TLB maintenance on context switches, for EL1&0 stage 1 translations the VMSA can distinguish between Global pages and Process-specific pages. The Address Space Identifier (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures. Similarly, for the Non-secure EL1&0 translation regime, the virtual machine identifier (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs.

The following sections describe the architectural requirements for Translation Lookaside Buffers (TLBs) and their maintenance:

- About ARMv8 Translation Lookaside Buffers (TLBs).
- TLB maintenance requirements and the TLB maintenance instructions on page D4-1828.

In these descriptions, TLB entries for a translation regime for a particular Exception level are out of context when executing at a higher Exception level.

About ARMv8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- Any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not out of context might be allocated to an enabled TLB at any time.

Note

An enabled TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as intermediate caching of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.
The following sections give more information about TLB implementation:

- **Global and process-specific translation table entries.**
- **TLB matching on page D4-1827.**
- **TLB behavior at reset on page D4-1827.**
- **TLB lockdown on page D4-1827.**
- **TLB conflict aborts on page D4-1828.**

See also **TLB maintenance requirements and the TLB maintenance instructions on page D4-1828.**

### Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by memory accesses at EL1 and EL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

- \( nG = 0 \) The translation is global, meaning the region is available for all processes.
- \( nG = 1 \) The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined in either the TTBR\_0\_EL1 or the TTBR\_1\_EL1.

As indicated by the nG field definitions, each non-global region has an associated Address Space Identifier (ASID). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

TTBR\_0\_EL1 and TTBR\_1\_EL1 each have an ASID field, and TCR\_EL1.A1 determines which of these fields defines the current ASID. See also **ASID size.**

---

**Note**

The selected ASID applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on TTBR\_0\_EL1 or on TTBR\_1\_EL1.

---

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the ARM architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

The EL2 translation regime and the EL3 translation regime do not support ASIDs, and all descriptors in these regimes are treated as global.

In a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final level of lookup are treated as being non-global, regardless of the value of the nG bit.

When a PE is using the VMSAv8-64 translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see **Control of Secure or Non-secure memory access on page D4-1798.**

### ASID size

In VMSAv8-64, the ASID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and ID\_AA64MMFR0\_EL1.ASIDBits identifies the supported size. When an implementation supports a 16-bit ASID, TCR\_EL1.AS selects whether the top 8 bits of the ASID are used. When the value of TCR\_EL1.AS is 0, ASID\[15:8]:

- Are ignored by hardware for every purpose other than reads of ID\_AA64MMFR0\_EL1.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

---

**Note**

VMSAv8-32 uses an 8-bit ASID. For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the ASID size remains at 8 bits. If the implementation supports 16-bit ASIDS, the 8-bit ASID used is zero-extended to 16 bits.
**TLB matching**

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1828 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This is an issue regardless of whether the translation table entries are global. In some cases, the TLB can hold two mappings for the same address, and this:

- Might generate a Data abort reported using the TLB Conflict fault code, see *TLB conflict aborts* on page D4-1828.

- Might lead to UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. For more information see Appendix J1 Architectural Constraints on UNPREDICTABLE behaviors.

**TLB behavior at reset**

The ARM architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

For ARMv8:

- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see *Controlling address translation stages* on page D4-1732.

- An implementation may require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. ARM recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in *TLB maintenance instructions* on page D4-1830.

- When TLBs that have not been invalidated by some mechanism since reset are enabled, the state of those TLBs is UNPREDICTABLE.

Similar rules apply to cache behavior, see *Behavior of caches at reset* on page D3-1693.

**TLB lockdown**

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.

- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the system instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-263. An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.

- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.
In an implementation that includes EL2, exceptions generated by problems related to TLB lockdown in a Non-secure EL1 mode, can be routed to either:

- Non-secure EL1, as a Data Abort exception.
- Non-secure EL2, as a Hyp Trap exception.

For more information, see Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1572.

**TLB conflict aborts**

ARMv8 includes the concept of a TLB conflict abort, and defines fault status encodings for such an abort, see ESR_EL1, Exception Syndrome Register (EL1) on page D7-1941.

An implementation can generate a TLB conflict abort if it detects that the address being looked up in the TLB hits multiple entries. This can happen if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed. If it happens, the resulting behavior is UNPREDICTABLE, but must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.

In some implementations, multiple hits in the TLB can generate a synchronous Data Abort or Prefetch Abort exception. In any case where this is possible it is IMPLEMENTATION DEFINED whether the abort is a stage 1 abort or a stage 2 abort.

Note

A stage 2 abort cannot be generated if stage 2 of the Non-secure EL1&0 translation regime is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of a TLB that can generate the abort.

Note

The TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses.

On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

**D4.7.2 TLB maintenance requirements and the TLB maintenance instructions**

Translation Lookaside Buffers (TLBs) are an implementation mechanism that caches translations or translation table entries. The ARM architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained. The following sections describe the VMSA TLB maintenance instructions:

- General TLB maintenance requirements on page D4-1829.
- TLB maintenance instructions on page D4-1830.
- Maintenance requirements on changing System register values on page D4-1840.
- Atomicity of register changes on changing virtual machine on page D4-1841.
General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk.
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction of the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for translation regimes that involve two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

Note

As stated in Global and process-specific translation table entries on page D4-1826, translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.

- Required to apply to stage 2 entries only, then:
  - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  - It must apply to caching structures that contain information only from stage 2 translation table entries.

- Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular VMID or ASID are changed, the corresponding entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including speculative execution, that uses the changed translation table entries.

Some system register bit descriptions state that the effect of the bit is permitted to be cached in a TLB. This means that all TLB entries that might be affected by a change in one of these bits must be invalidated whenever that bit is changed, to ensure that the effect of the change of that control bit is visible to subsequent execution including speculative execution, that uses those control bits. This invalidation is required in addition to, and after, the normal synchronization of the system registers described in Synchronization requirements for System registers on page D7-1902, and applies to any stage of address translation that is implemented for the translation regime, and VMID if appropriate, that is affected by that control bit.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see Cache maintenance requirement created by changing translation table attributes on page D4-1844.
Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access Flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB invalidation.

Special considerations can apply to translation table updates that change the memory type, cacheability, or output address of an entry, see Using break-before-make when updating translation table entries.

**Using break-before-make when updating translation table entries**

To avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the exclusive monitors, ARM strongly recommends the use of a break-before-make when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- A change of the memory type.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

A break-before-make approach on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution. This means the problems described at the start of this subsection cannot arise.

**TLB maintenance instructions**

The architecture defines TLB maintenance instructions, that provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same Inner Shareable shareability domain as the PE that executes the instruction.

The following subsubsections describe these instructions:

- TLB maintenance instruction syntax on page D4-1831.
- Operation of the TLB maintenance instructions on page D4-1832.
- Scope of the A64 TLB maintenance instructions on page D4-1833.
- Invalidation of TLB entries from stage 2 translations on page D4-1836.
- Broadcast TLB maintenance between AArch32 and AArch64 on page D4-1837.
- Broadcast TLB maintenance with different translation granule sizes on page D4-1838.
- Ordering and completion of TLB maintenance instructions on page D4-1838.
- TLB maintenance in the event of TLB conflict on page D4-1839.
- The interaction of TLB lockdown with TLB maintenance instructions on page D4-1839.

TLB maintenance instructions on page C5-252 describes the encoding of the TLB maintenance instructions.
**TLB maintenance instruction syntax**

The A64 syntax for TLB maintenance instructions is:

```
TLBI <operation>{, <Xt>}
```

Where:

- `<operation>` is one of `ALLE1`, `ALLE2`, `ALLE3`, `ALLE1IS`, `ALLE2IS`, `ALLE3IS`, `VMALLE1`, `VMALLE1IS`, `VMALLE1E1`, `VMALLE1E1IS`, `VMALLE2E1`, `VMALLE2E1IS`, `ASIDE1`, `ASIDE1E1`, `ASIDE1E1IS`, `VA(L)E1`, `VA(L)E2`, `VA(L)E3`, `VA(L)E1IS`, `VA(L)E2IS`, `VA(L)E3IS`, `VAA(L)E1`, `VAA(L)E1IS`, `IPAS2(L)E1`, or `IPAS2(L)E1IS`.

- `<operation>` has a structure of `<type>{L}<level>{,IS}` where:
  - `<type>` is one of:
    - `ALL`: All translations used at `<level>`.
      - For the scope of `ALL` instructions see `ALL` on page D4-1833.
      - The `ALL` instructions are valid for all values of `<level>`.
    - `VMALL`: All stage 1 translations used at `<level>` with the current VMID, if appropriate.
      - For the scope of the `VMALL` instructions see `VMALL` on page D4-1834.
      - The `VMALL` instructions are valid only when `<level> == E1`.
    - `VMALLS12`: All stage 1 and stage 2 translations used at EL1 with the current VMID, if appropriate.
      - For the scope of the `VMALLS12` instructions see `VMALLS12` on page D4-1834.
      - The `VMALLS12` instructions are valid only when `<level> == E1`.
    - `ASID`: All translations used at EL1 with the supplied ASID.
      - For the scope of the `ASID` instructions see `ASID` on page D4-1834.
      - The `ASID` instructions are valid only when `<level> == E1`.
    - `VA{L}`: Translations used at `<level>` for the specified address and, if appropriate, the specified ASID.
      - For the scope of the `VA` instructions see `VA` on page D4-1834.
      - For the scope of the `VAL` instructions see `VAL` on page D4-1835.
      - The `VA{L}` instructions are valid for all values of `<level>`.
    - `VAA{L}`: Translations used at `<level>` for the specified address, for all ASID values, if appropriate.
      - For the scope of the `VAA` instructions see `VAA` on page D4-1835.
      - For the scope of the `VAA` instructions see `VAA` on page D4-1835.
      - The `VAA{L}` instructions are valid only when `<level> == E1`.
    - `IPAS2{L}`: Translations used at `<level>` for the specified IPA that are held in stage 2 only caching structures.
      - For the scope of the `IPAS2` instructions see `IPAS2` on page D4-1835.
      - For the scope of the `IPAS2` instructions see `IPAS2` on page D4-1835.
      - The `IPAS2{L}` instructions are valid only when `<level> == E1`.

- `<Xt>` is an optional parameter that indicates that the invalidation only applies to caching of entries returned from the final lookup level of the translation table walk.

- `<level>` defines the Exception level of the translation regime that the invalidation applies to. Is one of:
  - `E1`: EL1.
  - `E2`: EL2.
  - `E3`: EL3.

An instruction that applies to the translation regime of an Exception level higher than the Exception level at which the instruction is executed is UNDEFINED.
TLBI ALLE1(IS), TLBI IPAS2[L]E1(IS) and TLBI VMALLS12E1(IS) are UNDEFINED at EL1.

--- Note ---

All TLB maintenance instructions are UNDEFINED at EL0.

--- IS ---

When present, it indicates that the function applies to all TLBs in the Inner Shareable shareability domain.

--- <Xt> ---

Passes one or both of an address and an ASID as an argument, where required. <Xt> is required for the TLB ASID, TLB VA(L), TLB VAA(L), and TLB IPAS2(L) instructions.

If EL2 is not implemented, the TLBI VA(L)E2, TLBI VA(L)E2IS, TLBI ALLE2, and TLBI ALLE2IS instructions are UNDEFINED.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds a virtual address, an ASID, or both, use the following register argument format:

- Bits[63:48] ASID. These bits are RES0 if the instruction does not require an ASID argument.
- Bits[47:44] RES0.
- Bits[43:0] VA[55:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
  - 4KB granule size All bits are valid and used for the invalidation.
  - 16KB granule size Bits[1:0] RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
  - 64KB granule size Bits[3:0] are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

These bits are RES0 if the instruction does not require a VA argument.

For TLB maintenance instructions that take an address argument, hardware interprets VA[63:56] as each having the same value as VA[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the VA is only 32-bit, then software must treat VA[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of ASID then the upper 8 bits of the ASID are RES0 when the context being invalidated only uses 8 bits.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds an IPA, use the following register argument format:

- Bits[63:36] RES0.
- Bits[35:0] IPA[47:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
  - 4KB granule size All bits are valid and used for the invalidation.
  - 16KB granule size Bits[1:0] RES0 and ignored when the instruction is executed, because IPA[13:12] have no effect on the operation of the instruction.
  - 64KB granule size Bits[3:0] are RES0 and ignored when the instruction is executed, because IPA[15:12] have no effect on the operation of the instruction.

--- Operation of the TLB maintenance instructions ---

Any TLB maintenance instruction can affect any TLB entries that are not locked down.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

--- Note ---

Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.
If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

* The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.

* **SCR_EL3.NS** modifies the effect of the TLB maintenance instructions as follows:
  - For instructions that apply to the EL1&0 translation regime, the **SCR_EL3.NS** bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.

    **Note**
    If EL3 is not implemented, then there is only a single EL1&0 translation regime.

    — For instructions that apply to the EL2 translation regime, the **SCR_EL3.NS** bit must be 1 or the instruction is UNDEFINED.
    — For instructions that apply to the EL3 translation regime, the **SCR_EL3.NS** bit has no effect.

* An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.

* Previous versions of the ARM architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of ARMv7, ARM deprecated any use of these instructions. In ARMv8:
  - AArch64 state does not include any of these instructions.
  - AArch32 state includes some of these instructions, but ARM deprecates their use.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

**Note**
The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB

**Scope of the A64 TLB maintenance instructions**

The TLB invalidation instruction `<type>` affects the different possible cached entries in the TLB as follows:

**ALL**
The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with the state specified by **SCR_EL3.NS**.

For entries from the Non-secure EL1&0 translation regime, **ALL** applies to entries with any VMID.

For entries from the EL1&0 translation regimes, **ALL** applies to:

* Global entries.
* Non-global entries with any ASID.
VMALL

The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

• The Security state specified by SCR_EL3.NS.
• For the Non-secure EL1&0 translation regime, the current VMID.

For entries from the EL1&0 translation regimes that meet the other specified conditions, VMALL applies to:

• Global entries.
• Non-global entries with any ASID.

VMALL is valid only for EL1.

VMALLS12

The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

• The Security state specified by SCR_EL3.NS.
• For the Non-secure EL1&0 translation regime, the current VMID.

For entries from the EL1&0 translation regimes that meet the other specified conditions, VMALLS12 applies to:

• Global entries.
• Non-global entries with any ASID.

VMALLS12 is valid only for EL1.

--- Note

If EL2 is not implemented, or if the TLBI VMALLS12 instruction is executed when the value of SCR_EL3.NS is 0, the instruction is not UNDEFINED but it has the same effect as TLBI VMALL. This is because there are no stage 2 translations to invalidate.

ASID

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

• The Security state specified by SCR_EL3.NS.
• For the EL1&0 translation regimes, the specified ASID, if either:
  — The entry is from a level of lookup above the final level.
  — The entry is a non-global entry from the final level of lookup.
• For the Non-secure EL1&0 translation regime, the current VMID.

ASID is valid only for EL1.

VA

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

• The Security state specified by SCR_EL3.NS.
• For the EL1&0 translation regimes, the specified ASID, if either:
  — The entry is from a level of lookup above the final level.
  — The entry is a non-global entry from the final level of lookup.
• For the Non-secure EL1&0 translation regime, the current VMID.

For entries from the EL1&0 translation regimes that meet the other specified conditions, VA applies to Global entries.
The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with all of:

- The Security state specified by SCR_EL3.NS.
- For the EL1&0 translation regimes, the specified ASID, if the entry is non-global.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from the EL1&0 translation regimes that meet the other specified conditions, VAL applies to Global entries.

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from the EL1&0 translation regimes that meet the other specified conditions, VAA applies to:

- Global entries.
- Non-global entries with any ASID.

The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from the EL1&0 translation regimes that meet the other specified conditions, VAAL applies to:

- Global entries.
- Non-global entries with any ASID.

The invalidation applies to all cached copies of the stage 2 translation table entries from any level of the translation table walk required to translate the specified IPA, that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current VMID.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the SCR_EL3.NS==0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2 instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-1836.

The invalidation applies to cached copies of the stage 2 translation table entry from the final level of the stage 2 translation table walk required to translate the specified IPA, that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current VMID.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the SCR_EL3.NS==0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2L instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-1836.
The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process. Therefore, the following is a non-exhaustive list of control bits that do not affect how a TLB maintenance instruction updates the TLB entries:

**In AArch64**
- SCTLR_EL1.M, SCTLR_EL2.M, SCTLR_EL3.{M, RW}, HCR_EL2.{VM, RW}, TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, TCR_EL2.{TG0, T0SZ}, TCR_EL3.{TG0, T0SZ}, VTCR_EL2.{SL0, T0SZ}, TTBR0_EL1.ASID, TTBR1_EL1.ASID.

**In AArch32**
- SCTLR.M, HCR.VM, TTBCR.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1}, HTCR.T0SZ, VTCR.{SL0, T0SZ}, TTBR0.ASID, TTBR1.ASID, CONTEXTIDR.ASID.

---

**Note**

- ARM expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations ARM expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.

- The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, ARM recommends not invalidating entries that are not required to be invalidated.

- Dependencies on the VMID for the Non-secure EL1&0 translation regime apply even when HCR_EL2.VM is set to 0. Because the architecture does not require the VTTBR_EL2.VMID field to be reset in hardware, the reset routine of each active PE must initialize VTTBR_EL2.VMID[7:0] to a common value such as 0, even if stage 2 translation is not in use.

### Invalidation of TLB entries from stage 2 translations

The architectural requirements of the IPAS2 instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the IPA held in Xt for the current VMID, with the corresponding requirement for the broadcast versions of the instructions:

   ```
   TLBI IPAS2E1, Xt
   DSB
   TLBI VMALLE1
   ```

2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the virtual address VA (and the specified ASID when executing TLBI VAE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

   ```
   TLBI IPAS2E1, Xt
   DSB
   TLBI VAE1, Xt2  ; or TLBI VAAE1, Xt2
   ```

3. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the IPA produced by the last level of stage 1 translation table lookup for the virtual address VA (and ASID when executing TLBI VALE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

   ```
   TLBI IPAS2E1, Xt
   DSB
   TLBI VALE1, Xt2  ; or TLBI VAALE1, Xt2
   ```

---

**Note**

Sequences 1, 2, and 3 must use the TLBI IPAS2E1 instruction even when Non-secure EL1&0 stage 1 translation is disabled.
Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries that must be invalidated by an IPAS2L instruction are those that come from the final level of the translation table lookup.

**Broadcast TLB maintenance between AArch32 and AArch64**

In most cases, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch64 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch32, provided that the address, qualify the scope of the ASID and VMID matching requirements of the original instruction are met, as specified in *Scope of the A64 TLB maintenance instructions* on page D4-1833.

--- **Note** ---

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- If VA matching is required, the VA is 0x0000 FFFF FFFF or lower of the memory space.
- If ASID matching is required and the PE is using a 16-bit ASID, then the top 8 bits of the ASID are zero.

Except for the cases identified here, a TLB maintenance instructions affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch32 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the address, ASID, and VMID matching requirements of the original instruction are met, as specified in *Scope of the A64 TLB maintenance instructions* on page D4-1833. In addition, for the instruction executed in AArch32 state:

- For a TLBIMVAIS, TLBIMVALIS, TLBIMWALIS, TLBIMVAHIS, TLBIMWALH, or TLBIMWALIS instruction, the VA supplied as an argument is zero-extended.
- For a TLBIIPAS2IS or TLBIIPAS2LIS instruction, the IPA supplied as an argument is zero-extended.
- For a TLBIASIDIS, TLBIMVAIS, or TLBIMVALIS instruction, the ASID supplied as an argument is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID.

The virtual address from the instruction executed in AArch32 state is zero-extended, and the ASID is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID.

The exceptions to these general rules are as follows:

1. **An ARMv7 PE in the same Inner Shareable domain is treated in the same way as an ARMv8 PE for which EL3 is using AArch32, except that if an ARMv8 PE issues a broadcast instruction that does not exist in ARMv7, then that instruction is not required to have an effect on the TLBs of the ARMv7 PE. The instructions that do not exist in ARMv7 include the following TLB maintenance instructions that ARMv8 adds to the T32 and A32 instruction sets:**
   - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:
     - TLBIMWALIS, TLBIMVALIS, TLBIMWALH, TLBIMVALH, TLBIMWAAL, and TLBIMWALH.
   - The following instructions that operate by IPA on TLB entries for stage 2 translations:
     - TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, and TLBIIPAS2L.

2. **The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Sharable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to the general rules:**
   - If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the broadcast AArch32 TLB maintenance instruction has any effect on either:
     - The EL3 translation regime of the PEs with EL3 using AArch64.
     - The Secure EL1 translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure EL1 translation regime is using AArch64 or AArch32.
If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

--- Note ---

While the exceptions to the general rule mean the architecture does not require the specified TLB invalidations, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such broadcast instructions affect these translation regimes.

--- Broadcast TLB maintenance with different translation granule sizes ---

In the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE:

- The TLB maintenance instruction specifying a virtual address and affecting the EL2 translation regime or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime.

- The TLB maintenance instruction specifying a virtual address and affecting the EL1 translation regime is broadcast from a PE using one stage 1 translation granule size for that translation regime for a particular ASID (if applicable), VMID (if applicable), and Security state, to a PE where EL1 for the same ASID (if applicable), VMID (if applicable), and Security state, is using a different stage 1 translation granule size.

- The TLB maintenance instruction specifying a virtual address and affecting the Non-secure EL1 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular ASID (if applicable) and VMID, to a PE where EL1 for the same ASID (if applicable) and VMID is using a different stage 2 translation granule size.

- The TLB maintenance instruction specifying an intermediate physical address and affecting the Non-secure EL1 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular VMID to a PE where EL1 for the same VMID is using a different stage 2 translation granule size.

--- Ordering and completion of TLB maintenance instructions ---

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

- Any load or store instruction, unless a DSB is executed between the load or store and the TLB maintenance instruction.

--- Note ---

In the ARM architecture, a translation table walk is considered to be a separate observer, and a store to translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the store to the translation tables.

- Another TLB maintenance instruction, unless a DSB is executed between the instructions.

- A data or instruction cache maintenance instruction, unless a DSB is executed between the instructions.
For AArch64 execution, the completion rules are:

- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated have been observed by all observers to the extent that those accesses are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the accesses. In addition, after the TLB invalidate instruction is complete, no new memory accesses using those TLB entries that can be observed by those observers entries are performed.

[Note]

For TLB maintenance instructions that affect other PEs, the memory accesses from those PEs that used the TLB entries that have been invalidated are included in the set of memory accesses that must have been observed when the TLB maintenance instruction is complete.

- A TLB maintenance instruction can complete at any time after it is issued, but is only guaranteed to be complete after the execution of DSB by the PE that executed the TLB maintenance instruction.

- The effects of a completed TLB maintenance instruction are only guaranteed to be visible on the PE that executed the instruction after the execution of an ISB instruction by the PE that executed the TLB maintenance instruction.

[Note]

In all cases in this section, where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores.

**TLB maintenance in the event of TLB conflict**

In the event that multiple entries in the TLB are being used to translate a given address (which implies that an attempt to access the given address might give rise to a TLB Conflict abort), it is IMPLEMENTATION DEFINED as to the form of TLB maintenance operation that the software must perform in order to be guaranteed that all TLB entries associated with the given address and translation regime have been invalidated. In all cases, an ALL or VMALL form of TLB maintenance operation that targets the given translation regime is guaranteed to remove all entries within that regime, even if there are multiple, conflicting TLB entries for any given address within that regime.

**The interaction of TLB lockdown with TLB maintenance instructions**

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on a locked TLB entry of a TLB invalidate all operation that would invalidate that entry if the entry was not locked is IMPLEMENTATION DEFINED. However, the instruction operation must be implemented as one of the following options:
  - The operation has no effect on entries that are locked down.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.

  Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see *Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page D1-1572.

[Note]

These options permit a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on a locked TLB entry of a TLB invalidate by VA or invalidate by ASID match operation that would invalidate that entry if the entry was not locked is IMPLEMENTATION DEFINED. However, the operation must implement one of the following options:
  - The locked entry is invalidated in the TLB.
The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by VA, this means the PE treats the operation as a NOP.

- The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see ESR_EL1, Exception Syndrome Register (EL1) on page D7-1941.

--- Note ---

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must provide an IMPLEMENTATION DEFINED mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page D3-1709.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of system control registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in system control registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The system control register changes that maintenance requirement applies to are:

- Any change to the MAIR_EL1, MAIR_EL2, or MAIR_EL3 registers.
- Any change to the AMAIR_EL1, AMAIR_EL2, or AMAIR_EL3 registers.
- Any change to SCTLR_EL1.EE, SCTLR_EL2.EE, or SCTLR_EL3.EE.
- Any change to SCTLR_EL1.WXN, SCTLR_EL2.WXN, or SCTLR_EL3.WXN.
- Any change to any of the SCR_EL3.\{RW, SIF\} bits.
- Any change to any of the HCR_EL2.\{RW, DC, PTW, VM\} bits. See also Changing HCR_EL2.PTW.
- Any changes to the registers that control address translation:
  - Any change to any of the TCR_EL1, TCR_EL2, TCR_EL3, or VTCR_EL2 registers.
  - Any change to the TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, TTBR0_EL3, or VTTBR_EL2 registers.

Changing HCR_EL2.PTW

When the value of the Protected table walk bit, HCR_EL2.PTW, is 1, a stage 1 translation table access in the Non-secure EL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that
depend on the effect of HCR_EL2.PTW. Therefore, if the value of HCR_EL2.PTW is changed without a change to
the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software
at Non-secure EL1 or EL0. If this is not done, behavior is UNPREDICTABLE.

**Atomicity of register changes on changing virtual machine**

From the viewpoint of software executing at Non-secure EL1 or EL0, when there is a switch from one virtual
machine to another, the registers that control or affect address translation must be changed atomically. This applies
to the registers for the Non-secure EL1&0 translation regime. This means that all of the following registers must
change atomically:

- The registers associated with the stage 1 translations:
  - MAIR_EL1 and AMAIR_EL1.
  - TTBR0_EL1, TTBR1_EL1, TCR_EL1, and CONTEXTIDR_EL1.
  - SCTLR_EL1.

- The registers associated with the stage 2 translations:
  - VTTBR_EL2 and VTCR_EL2.
  - MAIR_EL2 and AMAIR_EL2.
  - SCTLR_EL2.

--- Note ---

Only some bits of SCTLR_EL1 affect the stage 1 translation, and only some bits of SCTLR_EL2 affect the stage 2
translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic
with the other register updates.

These registers apply to execution using the Non-secure EL1&0 translation regime. However, when updated as part
of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of
context when they are updated, and no synchronization precautions are required.

**Use of out-of-context translation regimes**

The architecture requires that:

- When executing at EL3, EL2, or Secure EL1, an implementation must not use the registers associated with
  the Non-secure EL1&0 translation regime for speculative memory accesses.

- When executing at EL3 or Secure EL1, an implementation must not use the registers associated with the EL2
  translation regime for speculative memory accesses.

- When executing at EL3, EL2, or Non-secure EL1, an implementation must not use the registers associated
  with the Secure EL1 translation regime for speculative memory accesses.
D4.8 Caches in a VMSA implementation

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

• Summarizes the architectural requirements for the interaction between caches and address translation.
• Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

• Data and unified caches.
• Instruction caches.

In addition, Cache maintenance requirement created by changing translation table attributes on page D4-1844 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see Cache maintenance instructions on page D3-1700, that describes the cache maintenance instructions in the A64 instruction set.

D4.8.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access that is not UNPREDICTABLE.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

• Two writes to the same PA occur in program order.
• A read of a PA returns the value of the last successful write to that PA.
• A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as Physically-indexed, physically-tagged (PIPT) caches.

D4.8.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

• PIPT instruction caches.
• Virtually-indexed, physically-tagged (VIPT) instruction caches.
• ASID and VMID tagged Virtually-indexed, virtually-tagged (VIVT) instruction caches.

The CTR_EL0.L1Ip field identifies the form of the instruction caches.
The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

- PIPT instruction caches.
- VIPT instruction caches.
- ASID and VMID tagged VIVT instruction caches.
- The IVIPT Extension on page D4-1844.

--- Note ---

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or ASID and VMID tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT instruction caches

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches that are not UNPREDICTABLE.

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see The IVIPT Extension on page D4-1844.

VIPT instruction caches

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches that are not UNPREDICTABLE, except for the effect of memory address translation on instruction cache invalidate by address operations.

--- Note ---

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see The IVIPT Extension on page D4-1844.

ASID and VMID tagged VIVT instruction caches

For ASID and VMID tagged VIVT instruction caches, if the instructions at any virtual address change, for a given translation regime and a given ASID and VMID, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the stage of address translation.
- Writing new mappings to the translation tables.
Any change to the TCR or TTBR for the current translation regime, unless:
- For a change to the Secure EL1&0 translation regime, the change is accompanied by a change to the ASID.
- For a change to the stage 1 translations of the Non-secure EL1&0 translation regime, the change is accompanied by a change to the ASID or VMID.
- For a change to the stage 2 translations of the Non-secure EL1&0 translation regime, the change is accompanied by a change to the VMID.

--- Note ---
For ASID and VMID tagged VIVT instruction caches only, for a given translation regime and a given ASID and VMID, as appropriate, invalidation is not required if a change to the translations is such that the instructions associated with the non-faulting translations of a virtual address remain unchanged through the change to the translations, even if the physical locations being mapped to by the changed translation have been written as part of changing the translation.

Examples of situations where this might occur include:
- Copy-on-Write.
- Demand Paging of memory locations to/from disk.

This does not apply for VIPT or PIPT instruction caches, because those caches hold copies of physical addresses, and therefore must be invalidated when the contents are written to, to avoid the use of stale entries.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from an ASID and VMID tagged VIVT instruction cache is to invalidate the entire instruction cache.

The IVIPT Extension

An implementation in which the instruction cache exhibits the behaviors described in PIPT instruction caches on page D4-1843, or those described in VIPT instruction caches on page D4-1843, is said to implement the IVIPT Extension to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:
- Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

D4.8.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in General TLB maintenance requirements on page D4-1829. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:
- Write-Back to Write-Through
- Write-Back to Non-cacheable
- Write-Through to Non-cacheable
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.
Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from the cache.
3. Change the shareability attributes to the required new values.
Chapter D5
The Performance Monitors Extension

This chapter describes the ARMv8 implementation of the ARM Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the Performance Monitor Unit (PMU) architecture, PMUv3. It contains the following sections:

- About the Performance Monitors on page D5-1848.
- Accuracy of the Performance Monitors on page D5-1851.
- Behavior on overflow on page D5-1853.
- Attributability on page D5-1856.
- Effect of EL3 and EL2 on page D5-1857.
- Event filtering on page D5-1859
- Performance Monitors and Debug state on page D5-1861.
- Counter enables on page D5-1862.
- Counter access on page D5-1863.
- Events, Event numbers and mnemonics on page D5-1865.
- Performance Monitors Extension registers on page D5-1884.
- Pseudocode description on page D5-1887.

Note

Table J11-1 on page J11-5816 disambiguates the general register references used in this chapter.
D5.1 About the Performance Monitors

In ARMv8-A, the Performance Monitors Extension is an OPTIONAL feature of an implementation, but ARM strongly recommends that ARMv8-A implementations include version 3 of the Performance Monitors Extension, PMUv3.

--- Note ---
No previous versions of the Performance Monitors Extension can be implemented in ARMv8.

---

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see *Time as measured by the Performance Monitors cycle counter on page D5-1850.*
- A number of 32-bit event counters. The event counted by each counter is programmable. ARMv8 provides space for up to 31 counters. The actual number of counters is IMPLEMENTATION DEFINED, and the specification includes an identification mechanism.

--- Note ---
ARM recommends that at least two counters are implemented, and that hypervisors provide at least this many counters to guest operating systems.

---

- Controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Enabling interrupts on overflow.

Monitoring software can enable the cycle counter independently of the event counters.

The events that can be monitored split into:

- Architectural and microarchitectural events that are likely to be consistent across many microarchitectures.
- Implementation-specific events.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

--- Note ---
Implementations that include PMUv3 must, as a minimum requirement, implement a subset of the common events. See *Common event numbers on page D5-1868.*

---

- Reserves a large event number space for IMPLEMENTATION DEFINED events.

The full set of events for an implementation is IMPLEMENTATION DEFINED. ARM recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

The event numbers of the common events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

When a implementation supports monitoring of an event that is assigned a common event number, ARM strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from the IMPLEMENTATION DEFINED range.

--- Note ---
ARM might define other common event numbers. This is one reason why software must not assume that an event with an assigned common event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

---
When an implementation includes the Performance Monitors Extension, ARMv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A system register interface. This interface is mandatory.
- An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See Chapter 12 Recommended Memory-mapped Interfaces to the Performance Monitors.

An operating system can use the System registers to access the counters. This supports a number of uses, including:

- Dynamic compilation techniques.
- Energy management.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

There are many situations where performance monitoring features integrated into the implementation are valuable for applications and for application development. When an operating system does not use the Performance Monitors itself, ARM recommends that the operating system enables application software to access the Performance Monitors.

A hypervisor running on the PE can limit the access of a Non-secure operating system to the Performance Monitors.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the ARMv8 architecture defines both AArch64 and AArch32 system registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

- When executing in AArch64 state, PMCCNTR_EL0, see PMCCNTR_EL0, Performance Monitors Cycle Count Register on page D7-2226.
- When executing in AArch32 state, PMCCNTR, see PMCCNTR, Performance Monitors Cycle Count Register on page G6-4806.

The ARMv8 definition of the PMDEVARCH.ARCHID field specifies the Performance Monitors architecture version as PMUv3. This indicates that the Performance Monitors Extension conforms to the memory-mapped programmers’ model described in this Manual.

Note

The PMUv3 memory-mapped programmers’ model can be used by devices other than ARMv8 processors. Software must determine whether the PMU is attached to an ARMv8 processor by using the PMDEVAFF0 and PMDEVAFF1 registers to discover the affinity of the PMU to any ARMv8 processors.
D5.1.1 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through PMCCNTR_EL0 or PMCCNTR, increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

--- Note ---

- This means that, in an implementation where PEs are multi-threaded, the counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.

- Although the architecture requires that direct reads of PMCCNTR_EL0 or PMCCNTR occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the PMCCNTR_EL0 or PMCCNTR is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D5.1.2 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a Trace extension, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

ARM recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the Trace extension to pass in events to be counted.

D5.1.3 Interaction with power saving operations

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.
D5.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See Non-invasive behavior.
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See A reasonable degree of inaccuracy.
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following:
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D5.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multi-tasking operating system. As such, a reasonable variation in performance is permissible.

Note: Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

ARM does not define a reasonable variation in performance, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

Note: For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative IMPLEMENTATION DEFINED event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an IMPLEMENTATION DEFINED control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

D5.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. ARM does not define a reasonable degree of inaccuracy but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
• In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.

• Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

—— Note ———

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision.

A change of Security state can also affect the accuracy of the Performance Monitors, see Interaction with EL3 on page D5-1857.

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.
D5.3 Behavior on overflow

All events are counted in 32-bit wrapping counters, that overflow when they wrap. The cycle counter, PMCCNTR, is a 64-bit wrapping counter, that is configured by PMCR.LC to either:

- Signal an overflow when bit PMCCNTR[63] overflows.
- Signal an overflow when bit PMCCNTR[31] overflows into bit PMCCNTR[32].

On a Performance Monitors counter overflow:

- An overflow status bit is set to 1. See PMOVSCLR.
- An interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see Generating overflow interrupt requests.
- The counter continues counting events.

D5.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See PMINTENSET on page J11-5818 and PMINTENSEL on page J11-5818.

The overflow interrupt request is a level-sensitive request.

--- Note ---
- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- ARM recommends that the overflow interrupt requests:
  - Translate into a PMUIRQ signal, so that they are observable to external devices.
  - Connect on an IMPLEMENTATION DEFINED generic interrupt controller as a Private Peripheral Interrupt (PPI) for the originating processor. See the ARM Generic Interrupt Controller Architecture Specification for information about PPIs.
  - Connect to a Cross Trigger Interface (CTI), see Chapter H5 The Embedded Cross Trigger Interface.
- ARM strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same System Peripheral Interrupt (SPI) identifier.
- From GICv3, the ARM® Generic Interrupt Controller Architecture Specification recommends that the Private Peripheral Interrupt (PPI) with ID 23 is used for overflow interrupt requests.

Counters overflow when counting one or more events generates an unsigned carry out. Software can write to the counters to control the frequency at which interrupt requests occur. For counters other than the cycle counter, the counter is always a 32-bit unsigned wrapping value. For example, software might set a counter to 0xFFFF0000, to generate another counter overflow after 65536 increments, and reset it to this value every time an overflow interrupt occurs.

--- Note ---
If an event can occur multiple times in a single clock cycle then counter overflow can occur without the counter registering a value of zero.

For the cycle counter, software can program PMCR.LC to treat the counter as either a 64-bit or a 32-bit unsigned value.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any given PMNx counter, when the value of PMOVSSSET[x] is 1, the value of PMINTENSET[x] is 1, and one of the following is true:
  - EL2 is not implemented and the value of PMCR.E is 1.
  - EL2 is implemented, x is less than the value of HDCR.HPMN, and the value of PMCR.E is 1.
EL2 is implemented, \( x \) is greater than or equal to the value of HDCR.HPMN, and the value of HDCR.HPME is 1.

- The cycle counter, when the values of PMOVSET[31], PMINTENSET[31], and PMCR.E are all 1. The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from PMN\( x \) where \( x \) is greater than or equal to the value of HDCR.HPMN can be signaled from all modes and states but only if the value of HDCR.HPME is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing to PMOVSCLR[\( x \)] to clear the overflow bit to 0.

D5.3.2 Pseudocode description of overflow interrupt requests

The CheckForPMUOverflow() pseudocode function signals PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface. In AArch64 state, the pseudocode function is as follows:

```c
// AArch64.CheckForPMUOverflow()
// =============================
// Signal Performance Monitors overflow IRQ and CTI overflow events

boolean AArch64.CheckForPMUOverflow()
{    
  pmuirq = (PMCR_EL0.E == '1' && PMINTENSET_EL1<31> == '1' && PMOVSSET_EL0<31> == '1');
  for n = 0 to UInt(PMCR_EL0.N) - 1
    if HaveEL(EL2) then
      E = (if n < UInt(MDCR_EL2.HPMN) then PMCR_EL0.E else MDCR_EL2.HPME);
    else
      E = PMCR_EL0.E;
    if E == '1' && PMINTENSET_EL1<n> == '1' && PMOVSSET_EL0<n> == '1' then pmuirq = TRUE;
  SetInterruptRequestLevel(InterruptID_PMUIRQ, if pmuirq then HIGH else LOW);
  CTI_SetEventLevel(CrossTriggerIn_PMUOverflow, if pmuirq then HIGH else LOW);
  // The request remains set until the condition is cleared. (For example, an interrupt handler
  // or cross-triggered event handler clears the overflow status flag by writing to PMOVSCLR_EL0.)
  return pmuirq;
}
```

In AArch32 state, the function is as follows:

```c
// AArch32.CheckForPMUOverflow()
// =============================
// Signal Performance Monitors overflow IRQ and CTI overflow events

boolean AArch32.CheckForPMUOverflow()
{    
  if !ELUsingAArch32(EL1) then return AArch64.CheckForPMUOverflow();
  pmuirq = (PMCR.E == '1' && PMINTENSET<31> == '1' && PMOVSSET<31> == '1');
  for n = 0 to UInt(PMCR.N) - 1
    if HaveEL(EL2) then
      hpmn = if !ELUsingAArch32(EL2) then MDCR_EL2.HPMN else HDCR.HPMN;
      hpme = if !ELUsingAArch32(EL2) then MDCR_EL2.HPME else HDCR.HPME;
      E = (if n < UInt(hpmn) then PMCR.E else hpme);
    else
      E = PMCR.E;
    if E == '1' && PMINTENSET<n> == '1' && PMOVSSET<n> == '1' then pmuirq = TRUE;
  SetInterruptRequestLevel(InterruptID_PMUIRQ, if pmuirq then HIGH else LOW);
  CTI_SetEventLevel(CrossTriggerIn_PMUOverflow, if pmuirq then HIGH else LOW);
  // The request remains set until the condition is cleared. (For example, an interrupt handler
  // or cross-triggered event handler clears the overflow status flag by writing to PMOVSCLR_EL0.)
  return pmuirq;
}
```
return pmuirq;
D5.4 Attributability

An event caused by the PE counting the event is Attributable. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the processor.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multi-threaded implementation, an event might be Attributable either to the current Exception level alone, or to both the Exception level and the Security state of another processor with the same values for affinity level 1 and higher.

--- Note ---
A multi-threaded implementation is one where the value of MPIDR.MT is 1. In this section, when referring to a multi-threaded implementation, *thread* is used to mean processing elements with different affinity level 0 values and the same values for affinity level 1 and higher.

---

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable.

Unattributable events might be counted when Attributable events are not counted. See:
- *Interaction with EL3 on page D5-1857.*
- *Event filtering on page D5-1859.*
- *Performance Monitors and Debug state on page D5-1861.*

These sections are summarized by Table D5-1 for events Attributable to the processor, and Unattributable events.

D5.5 Effect of EL3 and EL2

This section describes the effects of implementing EL3 and EL2 on the Performance Monitors. It contains the following subsections:

- Interaction with EL3.
- Interaction with EL2 on page D5-1858.

D5.5.1 Interaction with EL3

While counting events is never prohibited in Non-secure state, there are some restrictions on counting events in Secure state. From reset, counting events Attributable to Secure state is prohibited in Secure state. When executing in AArch32 state, software can set SDCR.SPME to 1 to permit event counting in Secure state. In AArch64 state, software can set MDCR_EL3.SPME to 1 to permit event counting in Secure state.

Note

This enables a Secure Monitor to permit profiling within Secure state without having to configure an IMPLEMENTATION DEFINED debug authentication interface.

The system can use the external authentication interface to override SPME. For example, if SPNIDEN and NIDEN are HIGH then this permits event counting in Secure state, irrespective of the value in SDCR.SPME or MDCR_EL3.SPME.

If EL3 is not implemented, the behavior is as if the value of SDCR.SPME or MDCR_EL3.SPME is 1, as appropriate.

In summary, counting Attributable events in Secure state is prohibited unless any one of the following is true:

- EL3 is not implemented.
- EL3 is implemented, is using AArch64, and the value of MDCR_EL3.SPME is 1.
- EL3 is implemented, is using AArch32, and the value of SDCR.SPME is 1.
- EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0, and the value of SDER32_EL3 is 1.
- EL3 is implemented, and counting is permitted by an IMPLEMENTATION DEFINED authentication interface, ExternalSecureNoninvasiveDebugEnabled() \( \equiv \) TRUE.

Note

Software can read the Authentication Status register, DBGAUTHSTATUS, to determine the state of an IMPLEMENTATION DEFINED authentication interface.

The cycle counter, PMCCNTR, counts even when event counting is prohibited, unless PMCR.DP is set to 1 or the PE is in Debug state.

For each Unattributable event it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

Note

- Additional controls in PMCR, HDCR, PMCNTENSET, and PMCNTENCLR can also disable the event counters and the cycle counter.
- Controls in PMEVTYPE<\(n\)> and PMCCFILTR can filter out events based on Exception level and Security state.

This disabling of counters or filtering of events takes precedence over the authentication controls.

Note

See ProfilingProhibited() and CountEvents() in the Pseudocode description on page D5-1887 for more details.
If the implementation is multi-threaded, the value of PMEVTYPER<n>.MT is 1 and an event is Attributable to Secure state on another thread, then the event is not counted. Counting events Attributable to Secure state in Secure state is prohibited on the counting thread.

For example, if the value of SDCR.SPME is 0 on one thread, then it does not count events Attributable to Secure state on another thread. This remains the case even if the counting thread is in Non-secure state or the value of MDCR_EL3.SPME is 1 on the other thread, or both of these apply.

Otherwise, when the current configuration prohibits counting of events Attributable to Secure state in Secure state, it is IMPLEMENTATION DEFINED whether:

- Counting events Attributable to Secure state in Non-secure state is permitted.
- Counting Unattributable events related to other secure operations in the system is permitted.

Otherwise, counting events in Non-secure state is permitted.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether counting the event is permitted when counting of Attributable events is prohibited.

In AArch32 state, the Performance Monitors registers are Common registers, see Classification of System registers on page G4-4193.

The Performance Monitors registers are always accessible regardless of the values of the authentication signals and the SDER.SUNIDEN bit. Authentication controls whether the counters count events, it does not control access to the Performance Monitors registers.

The Performance Monitors are intended to be broadly accurate and statistically useful, see Accuracy of the Performance Monitors on page D5-1851. Some inaccuracy is permitted at the point of changing Security state, however. To avoid the leaking of information from the Secure state, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

### D5.5.2 Interaction with EL2

In an implementation that includes EL2, Non-secure software executing at EL2 can:

- Trap any attempt by the Guest OS to access the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state.
- Trap accesses to the PMCR, so that it can fully virtualize the PMU identity registers, PMCR.IMP and PMCR.IDCODE.
- Reserve the highest-numbered counters for its own use by overriding the value of PMCR.N seen by the Guest OS. The implementation must not permit a Guest OS to access the reserved counters.

HDCR controls Performance Monitors virtualization.

For more information see:

- Counter enables on page D5-1862.
- Counter access on page D5-1863.
D5.6 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D5.6.1 Filtering by Exception level and state

For each event counter PMEVTYPER<el> specifies the Exception levels in which the counter counts events Attributable to Exception levels.

PMCCFILTR_EL0 specifies the Exception levels in which the cycle counter counts.

If the value of PMEVTYPER<el> is 1 and an event is Attributable to another thread, then the implementation is multi-threaded and this filtering only applies using the current Exception level of the other thread, regardless of the Exception level of the counting thread. For example, if the value of PMEVTYPER<el> is 0 on one thread, then it does not count events Attributable to Secure state on another thread, even if the first thread is in Non-secure state and the value of MDCR_EL3.SPME is 1 on another thread.

Otherwise, for each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies.

For more information, see the individual register descriptions.

D5.6.2 Accuracy of event filtering

The PMU architecture does not require event filtering to be accurate.

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- Exception-related events.
- Software increment events.

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level from which the exception was taken. These events are:

- Exception taken.
- Instruction architecturally executed, condition code check pass, exception return.
- Instruction architecturally executed, condition code check pass, write to CONTEXTIDR.
- Instruction architecturally executed, condition code check pass, write to translation table base.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to CONTEXTIDR after the return from the exception.

Note

Unprivileged software cannot write to CONTEXTIDR.

Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening context synchronization operation must increment the event counter twice.
Pseudocode description of event filtering

The pseudocode for the CountEvents() function can be found in Pseudocode description on page D5-1887.
D5.7 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

If the implementation is multi-threaded and the value of PMEVTYPERRn_EL0 is 1, and the event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting processor is in Debug state. If the event might be counted, then the rules in Filtering by Exception level and state on page D5-1859 apply for the current Security state in Debug state.
D5.8 Counter enables

Table D5-2 shows an implementation that does not include EL2, and where the PMCR.E bit is a global counter enable bit, and PMCNTENSET provides an enable bit for each counter.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[x] == 0</th>
<th>PMCNTENSET[x] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMNx disabled</td>
<td>PMNx disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMNx disabled</td>
<td>PMNx enabled</td>
</tr>
</tbody>
</table>

If the implementation includes EL2, then in addition to the PMCR.E and PMCNTENSET enable bits:

- HDCR.HPME overrides the value of PMCR.E for counters configured for access in Hyp mode.
- HDCR.HPMN specifies the number of performance counters that the Guest OS can access. The minimum permitted value of HDCR.HPMN is 1, meaning there must be at least one counter that the Guest OS can access.

Table D5-3 shows the combined effect of all the counter enable controls.

<table>
<thead>
<tr>
<th>HDCR.HPME</th>
<th>PMCR.E</th>
<th>PMCNTENSET[x] == 0</th>
<th>PMCNTENSET[x] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>x &lt; HDCR.HPMN</td>
<td>PMNx disabled</td>
<td>PMNx disabled</td>
<td></td>
</tr>
<tr>
<td>x ≥ HDCR.HPMN</td>
<td>PMNx disabled</td>
<td>PMNx enabled</td>
<td></td>
</tr>
</tbody>
</table>

Note

The effect of HDCR.{HPME, HPMN} on the counter enables applies in both Security states. However, in Secure state the value returned for PMCR.N is not affected by HDCR.HPMN.

EL2 does not affect the enabling of PMCCNTR. Table D5-4 shows the PMCCNTR enables, for all implementations.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[31] == 0</th>
<th>PMCNTENSET[31] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMCCNTR disabled</td>
<td>PMCCNTR disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMCCNTR disabled</td>
<td>PMCCNTR enabled</td>
</tr>
</tbody>
</table>
D5.9 Counter access

All counters are accessible in EL3, Secure EL1 and EL2. If EL2 is implemented the hypervisor uses HDCR.HPMN to reserve an event counter, with the effect that software cannot access that counter and its associated state from Non-secure EL1 modes or from Non-secure EL0.

Note
This section describes a counter as being accessible from a particular Exception level and state. However, access to the registers are subject to the access permissions described in Access permissions on page D5-1884. In particular, accesses from EL0 might be UNDEFINED and accesses from Non-secure EL1 and EL0 might be trapped to EL2.

D5.9.1 Access at EL0

To allow self-profiling code executing at EL0 to make use of the Performance Monitors, three controls are provided in PMUSERENR_EL0.

For more information, see Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1565.

D5.9.2 PMNx event counters

For an implementation that includes EL2 and EL3, Table D5-5 shows how the values of the HDCR.HPMN field control the behavior of accesses to the PMNx event counter registers.

Note
Access to the Performance Monitors registers is also subject to the access permissions described in Access permissions on page D5-1884. In particular, accesses might be trapped to EL1 or EL2.

Table D5-5 Result of PMNx event counter accesses

<table>
<thead>
<tr>
<th>Condition</th>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL3</td>
<td>EL1</td>
</tr>
<tr>
<td>x &lt; HDCR.HPMN</td>
<td>Succeeds</td>
<td>Succeeds</td>
</tr>
<tr>
<td>x ≥ HDCR.HPMN</td>
<td>Succeeds</td>
<td>Succeeds</td>
</tr>
</tbody>
</table>

Where Table D5-5 shows no access:

- If PMSELR_SEL is x then:
  - A direct read of PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.
  - A direct write to PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.

- A direct read of PMEVTYPER<n> or PMEVCNTR<n> is CONSTRAINED UNPREDICTABLE.

- A direct write of PMEVTYPER<n> or PMEVCNTR<n> is CONSTRAINED UNPREDICTABLE.

- For direct reads and direct writes, PMOVCLRR[x], PMOVSET[x], PMCNTENSET[x], PMCNTENCLR[x], PMINTENSET[x], and PMINTENCLR[x] are RAZ/WI

- Direct writes to PMSWINC[x] are ignored.

- A direct write of 1 to PMCR,P does not reset PMNx.
Note

In Secure state, and in the Non-secure EL2 mode, the value of HDCR.HPMN does not affect the value returned for PMCR.N.

D5.9.3   CCNT cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. The only control over the cycle counter is an access permission control for EL0. See Access permissions on page D5-1884.
D5.10 Events, Event numbers and mnemonics

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

- Definitions.
- Common event numbers on page D5-1868.
- Common architectural event numbers on page D5-1870.
- Common microarchitectural event numbers on page D5-1873.
- Relationship between REFILL events and associated access events on page D5-1882.
- Required events on page D5-1882.
- IMPLEMENTATION DEFINED event numbers on page D5-1883.

D5.10.1 Definitions

The following subsections give more information about terms used in the event definitions:

- Definition of terms.
- Levels of caches and TLBs on page D5-1868.

Definition of terms

Speculatively executed

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

An instruction might create one or more microarchitectural operations (µ-ops) at any point in the execution pipeline. For the purpose of event counting, the µ-ops are counted. The definition of a µ-op is implementation specific. An architecture instruction might create more than one µ-op for each instruction. µ-ops might also be removed or merged in the execution stream, so an architecture instruction might create no µ-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of µ-ops is permitted.

This means there is no architecturally guaranteed relationship between a speculatively executed µ-op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, such as a mispredicted branch. Therefore, ARMv8-A defines these events as operation speculatively executed, where appropriate.

--- Note ---

The definition of speculatively executed does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 LDMM instruction of six registers into six µ-ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load µ-ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operation speculatively executed - Load) events.
- One (Operation speculatively executed - Integer data processing) event.
- One (Operation speculatively executed - Software change of the PC) event, if the PC was one of the six registers in the LDMM instruction.
Different groups of events can have different implementation-defined definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example are of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

### Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, PLI.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is implementation-defined. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

### Memory-read operations

A PE accesses memory through memory-read and memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instructions.
- The result of a speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or memory-write operations that miss in the cache.
- The execution of a data preload instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance instruction.

--- Note ---

A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is implementation-defined. For example, for some implementations an LDP instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.
Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instructions.
- The result of a speculatively executed memory-writing instructions.

Note

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see memory-read operations.
- The execution of a cache maintenance instruction.

Note

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

Note

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Instruction architecturally executed

Instruction architecturally executed is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a Simple sequential execution of the program. Therefore an instruction that has been executed and retired is defined to be architecturally executed. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

If an instruction that would be executed in a Simple sequential execution of the program generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its condition code check.
- A Compare and Branch on Zero, C8Z, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.
Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its condition code check.

For events that count only the execution of instructions that update context state, such as writes to the CONTEXTIDR, if such an instruction is executed twice without an intervening context synchronization operation, it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

--- Note ---
See Context synchronization operation for the definition of this term.

**Instruction architecturally executed, condition code check pass**

*Instruction architecturally executed, condition code check pass* is a class of events that explicitly do not occur for:

- A conditional instruction that fails its condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for *Instruction architecturally executed*.

**Levels of caches and TLBs**

The mapping of different levels of cache or TLB to the PMU events is determined by the implementation. Although the CLIDR_EL1, or the AArch32 CLIDR, defines the implemented levels of cache, the architecture does provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations.

### D5.10.2 Common event numbers

Table D5-6 lists the PMU architectural and microarchitectural event numbers in event number order.

D5.10.3 Common architectural event numbers

This section describes the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term *architecturally executed* means that the instruction flow is such that the counted instruction would have been executed in a *Simple sequential execution* model.

The common architectural event numbers are:

0x000, Instruction architecturally executed, condition code check pass, software increment

The counter increments on writes to the PMSWINC register.

If the PE performs two architecturally executed writes to the PMSWINC register without an intervening context synchronization operation, then the event is counted twice.

If PMEVTYPER<\texttt{EL}1.evtCount is set to 0x000, then in AArch64 state, counts MSR writes [n] to PMSWINC_EL0 with bit [n] set to 1.

If PMEVTYPER<\texttt{EL}1.MT is set to 1 then this counts writes by all processors at the same level 1 affinity and above in a multi-threaded implementation.
0x006, **Instruction architecturally executed, condition code check pass, load**

The counter increments for every executed memory-reading instruction.

--- **Note** ---

Event 0x006 does not count the return status value of a Store-Exclusive instruction.

---

Note: Whether the preload instructions `PRFM`, `PLD`, `PLDW`, `PLI` count as memory-reading instructions is **IMPLEMENTATION DEFINED**. ARM recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

0x007, **Instruction architecturally executed, condition code check pass, store**

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

0x008, **Instruction architecturally executed**

The counter increments for every architecturally executed instruction.

0x009, **Exception taken**

The counter increments for each exception taken. See *Exception-related events on page D5-1859*.

--- **Note** ---

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, *Exception entry on page D1-1516*.
- For exceptions taken to an Exception level using AArch32, *AArch32 state exception descriptions on page G1-3875*.

0x00A, **Instruction architecturally executed, condition code check pass, exception return**

The counter increments for each executed exception return instruction. See also *Exception-related events on page D5-1859*. The following sections define the counted instructions:

- For an exception return to an Exception level using AArch64, *Exception return on page D1-1533*.
- For an exception return to an Exception level using AArch32, *Exception return to an Exception level using AArch32 on page G1-3860*.

0x00B, **Instruction architecturally executed, condition code check pass, write to CONTEXTIDR**

The counter increments for every write to CONTEXTIDR. See *Exception-related events on page D5-1859*. If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening context synchronization operation, it is **CONSTRAINED UNPREDICTABLE** whether the first write is counted.

0x00C, **Instruction architecturally executed, condition code check pass, software change of the PC**

The counter increments for every software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data processing instructions that explicitly write to the PC.
- Exception return instructions, ERET and RET.

It is **IMPLEMENTATION DEFINED** whether the counter increments for any or all of:

- BRK and BKPT instructions.
- Undefined Instruction exceptions.
- The exception-generating instructions, SVC, IHC and SMC.
It is IMPLEMENTATION DEFINED whether an ISB is counted as a software change of the PC.
The counter does not increment for exceptions other than those explicitly identified in these lists.

--- Note ---
Conditional branches are only counted if the branch is taken.

**0x00D, Instruction architecturally executed, immediate branch**
The counter counts all immediate branch instructions that are architecturally executed.
In AArch32 state, the counter increments each time the PE executes one of the following instructions:
- **B** `<label>`.
- **BL** `<label>`.
- **BLX** `<label>`.
- **CBZ** `<Rn>`, `<label>`.
- **CBNZ** `<label>`.

In AArch64 state, the counter increments each time the PE executes an immediate branch instructions:
- **B** `<label>`.
- **B.cond** `<label>`.
- **BL** `<label>`.
- **CBZ** `<Rn>`, `<label>`.
- **CBNZ** `<Rn>`, `<label>`.
- **TBZ** `<Rn>`, `<label>`.
- **TBNZ** `<Rn>`, `<label>`.

--- Note ---
Conditional branches are always counted, regardless of whether the branch is taken.

If an ISB is counted as a software change of the PC instruction then it is IMPLEMENTATION DEFINED whether an ISB is counted as an immediate branch instruction.

**0x00E, Instruction architecturally executed, condition code check pass, procedure return**
In AArch32 state, the counter counts the following procedure return instructions:
- **BX R14**.
- **MOV PC, LR**.
- **POP {..., PC}**.
- **LDR PC, [SP], #offset**.

--- Note ---
The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:
- **BX R0**, because Rm != R14.
- **MOV PC, R0**, because Rm != R14.
- **LDM SP, {..., PC}**, because writeback is not specified.
- **LDR PC, [SP, #offset]**, because this specifies the wrong addressing mode.

In AArch64 state, the counter counts all architecturally executed **RET** instructions.

**0x00F, Instruction architecturally executed, condition code check pass, unaligned load or store**
The counter counts each memory-reading instruction or memory-writing instruction that accesses an unaligned address. It is IMPLEMENTATION DEFINED whether this event also counts each Alignment fault Data Abort exception.
See Unaligned data access on page E2-2435 for more information.

0x01C, Instruction architecturally executed, condition code check pass, write to TTBR

The counter counts writes to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and TTBR0 and TTBR1 in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of TTBR0 and TTBR1. See Exception-related events on page D5-1859.

If the PE executes two writes to the same TTBR, without an intervening context synchronization operation, it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to TTBR0_EL3.

If EL2 is implemented and using AArch64, the counter does not count writes to TTBR0_EL2 and to VTTBR_EL2.

If EL2 is implemented and using AArch32, the counter does not count writes to HTTBR and to VTTBR.

0x01E, Chain

For an odd-numbered counter, increments when an overflow occurs on the preceding even-numbered counter on the same PE. Even-numbered counters never cause this event count to increment.

The CHAIN event enables a system to provide either \(N\) 32-bit counters or \(N/2\) 64-bit counters. There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence or employ reasonable heuristics, to avoid tearing.

0x021, Instruction architecturally executed, branch.

The counter counts all branches on the architecturally executed path that would incur cost if mispredicted.

- Counts all branch instructions, memory-reading and data-processing instructions that explicitly write to the PC, at retirement.
- Counts both taken and not-taken branches.
- It is IMPLEMENTATION DEFINED whether this includes each of:
  - Unconditional direct branch instructions.
  - Exception-generating instructions.
  - Exception return instructions.
  - Context synchronization instructions.

D5.10.4 Common microarchitectural event numbers

This section describes the defined common microarchitectural event numbers.

The common microarchitectural events are features that are likely to be implemented across a wide range of implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that share it, ARM recommends that the resource implements its own event counters. An example of a resource that might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions relating to Level 1 caches generally assume the Level 1 cache is not shared.
The common microarchitectural event numbers are:

0x001, **Level 1 instruction cache refill**

The counter counts instruction memory accesses that cause a refill of at least the Level 1 instruction or unified cache. This includes each instruction memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

Cache maintenance instructions do not count as events.

See also *Relationship between REFILL events and associated access events* on page D5-1882.

0x002, **Level 1 instruction TLB refill**

The counter counts instruction memory accesses that cause a TLB refill of at least the Level 1 instruction TLB. This includes each instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also *Relationship between REFILL events and associated access events* on page D5-1882.

0x003, **Level 1 data cache refill**

The counter counts each memory-read operation or memory-write operation that causes a refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:

- Accesses that do not cause a new Level 1 cache refill but are satisfied from refilling data of a previous miss.
- Accesses to a cache line that generate a memory access but not a new linefill, such as write-through writes that hit in the cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 cache, for example:
  - A write of a full cache line from a coalescing buffer.
  - A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also *Relationship between REFILL events and associated access events* on page D5-1882

0x004, **Level 1 data cache access**

The counter counts each memory-read operation or memory-write operation that causes a cache access to at least the Level 1 data or unified cache. Each access to a cache line is counted including the multiple accesses of instructions, such as LDM or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.
Cache maintenance instructions do not count as events.

0x005, **Level 1 data TLB refill**

The counter counts each memory-read operation or memory-write operation that causes a TLB refill of at least the Level 1 data or unified TLB. It counts each read or write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also [*Relationship between REFILL events and associated access events* on page D5-1882](#).

0x010, **Mispredicted or not predicted branch speculatively executed**

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, ARM recommends that the counter counts all branches that are not taken.

0x011, **Cycle**

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a *WFI* or *WFE* instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the clocks are stopped by *WFI* and *WFE* instructions.

______ **Note** ______

Unlike PMCCNTR, this count is not affected by PMCR.DP, PMCR.D, or PMCR.C:

- The counter is not incremented in prohibited regions, so is not affected by PMCR.DP.
- The counter increments on every cycle, regardless of the setting of PMCR.D.
- The counter is reset when event counters are reset by PMCR.P, never by PMCR.C.

In a multi-threaded implementation, CPU_CYCLES counts each cycle for the multi-threaded processor, not only cycles for which this processor thread is active.

0x012, **Predictable branch speculatively executed**

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. ARM recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by BR_MIS_PRED.

If no program-flow prediction resources are implemented, this event is optional, but ARM recommends that BR_PRED counts all branches.
0x013, Data memory access

The counter counts memory-read or memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:

- Instruction memory accesses, see Definition of terms on page D5-1865.
- Translation table walks.
- Cache maintenance instructions.
- Write-back from any cache.
- Refilling of any cache.

0x014, Level 1 instruction cache access

The counter counts instruction memory accesses that access at least the Level 1 instruction or unified cache. Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

0x015, Level 1 data cache write-back

The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 2 cache or memory.
- A write-back of a recently-fetched cache line that has not been allocated to the Level 1 cache.
- Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back. Whether this also includes write-backs made as a result of cache maintenance instructions is IMPLEMENTATION DEFINED.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 2 cache or memory.
- Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back.

If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See Attributability on page D5-1856.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

0x016, Level 2 data cache access

The counter counts memory-read or memory-write operations, that the PE made, that access at least the Level 2 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 data, instruction, or unified caches. Each access to other Level 2 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share this cache.
- Cache maintenance instructions.
0x017, Level 2 data cache refill

The counter counts memory-read or memory-write operations, that the PE made, that access at least the Level 2 data or unified cache and cause a refill of a Level 1 data, instruction, or unified cache or of the Level 2 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1 and Level 2 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

• Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
• Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
• Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count:

• Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
• Accesses to the Level 2 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 2 cache.
• Accesses to the Level 2 cache that are part of a Level 1 cache refill or write-back that hit in the Level 2 cache so do not cause a refill from outside of the Level 1 and Level 2 caches.
• Operations made by other PEs that share this cache, as events on this PE.
• Cache maintenance instructions.
• A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 and Level 2 caches, for example:
  — A write-back from a Level 1 cache to a Level 2 cache.
  — A write from a coalescing buffer of a full cache line.
  — A DC ZVA operation.
• A write that misses in the cache, and writes through the cache without allocating a line.

See also Relationship between REFILL events and associated access events on page D5-1882.

0x018, Level 2 data cache write-back

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

• A write-back that causes data to be written to a Level 3 cache or memory.
• A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

• A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request.
• Write-backs made as a result of Cache maintenance instructions.

The counter does not count:

• The invalidation of a cache line without any write-back to a Level 3 cache or memory.
• Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
• Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back.
If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See *Attributability on page D5-1856.*

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

**0x019, Bus access**

The counter counts memory-read or memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. It must count accesses beyond the cache furthest from the PE for which accesses can be counted.

This means that:

- If Level 2 cache access events are implemented and no IMPLEMENTATION DEFINED events can count accesses for any caches outside a Level 2 cache, this counter increments for an access beyond the Level 2 cache.
- If Level 2 cache access events are not implemented and Level 1 cache access events are implemented, this counter increments for an access beyond the Level 1 cache.
- If neither Level 1 or Level 2 cache access events are implemented, this counter increments for all data accesses that the PE made.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from Level 1 and Level 2 data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data, such as barrier operations, is IMPLEMENTATION DEFINED.

Where an implementation has multiple external buses, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

**0x01A, Local memory error**

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

**0x01B, Operation speculatively executed**

The counter counts instructions that are speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. As a result, this event counts a larger number of instructions than the number of instructions architecturally executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x01D, Bus cycle**

The counter increments on every cycle of the external memory interface of the PE.

--- Note

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.
0x01F, **Level 1 data cache allocation without refill**
The counter increments on every write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example:
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

0x020, **Level 2 data cache allocation without refill**
The counter increments on every write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:
- A write-back from a Level 1 to Level 2 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

0x022, **Instruction architecturally executed, mispredicted branch**
The counter counts all instructions counted by BR_RETIRED that were not correctly predicted. If no program-flow prediction resources are implemented, this event counts all not-taken branches retired.

0x023, **No operation issued due to the frontend**
The counter counts every cycle on which no operation was issued because there are no operations available to issue from the frontend.

0x024, **No operation issued due to the backend**
The counter counts every cycle on which no operation was issued because either:
- The backend is unable to accept any of the operations available for issue.
- The backend is unable to accept any operations.
For example, the back end might be unable to accept operations because of a resource conflict or non-availability.

0x025, **Level 1 data or unified TLB access**
The counter counts each memory-read operation or memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB. Each access to a TLB record is counted including the multiple accesses of instructions, such as LDM or STM.
TLB maintenance instructions do not count as events.

0x026, **Level 1 instruction TLB access**
The counter counts each memory-read operation or memory-write operation that causes a TLB access to at least the Level 1 instruction or unified TLB.
TLB maintenance instructions do not count as events.

0x027, **Attributable Level 2 instruction cache access**
The counter counts attributable instruction memory accesses that access at least the Level 2 instruction or unified cache. Each Attributable access to other Level 2 instruction memory structures, such as refill buffers, is also counted.
See also *Attributability* on page D5-1856.

0x028, **Attributable Level 2 instruction cache refill**
The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 2 instruction or unified cache. This includes each Attributable memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
A refill includes any Attributable access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.
Cache maintenance instructions do not count as events.

See also:
- *Attributability* on page D5-1856.
- *Relationship between REFILL events and associated access events* on page D5-1882.

**0x029, Attributable Level 3 data cache allocation without refill**

The counter increments on every attributable write that writes an entire line into the Level 3 cache without fetching from outside the Level 3 cache, for example:
- An attributable write from a coalescing buffer of a full cache line.
- An attributable DC ZVA operation.

See also *Attributability* on page D5-1856.

**0x02A, Attributable Level 3 data cache refill**

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. Each Attributable access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts Attributable accesses to the Level 3 cache that cause a refill that is satisfied by another Level 3 data or unified cache, or memory.

A refill includes any Attributable access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:
- Accesses that do not cause a new Level 3 cache refill but are satisfied from refilling data of a previous miss.
- Accesses to a cache line that generate an Attributable memory access but not a new linefill, such as write-through writes that hit in the cache.
- Cache maintenance instructions.
- An Attributable write that writes an entire line to the cache and does not fetch any data from outside the Level 3 cache, for example:
  - An Attributable write of a full cache line from a coalescing buffer.
  - An Attributable DC ZVA operation.
- An Attributable write that misses in the cache, and writes through the cache without allocating a line.

See also:
- *Attributability* on page D5-1856.
- *Relationship between REFILL events and associated access events* on page D5-1882.

**0x02B, Attributable Level 3 data cache access**

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a cache access to at least the Level 3 data or unified cache. Each access to a cache line is counted including the multiple accesses of instructions, such as LDM or STM. Each access to other Level 3 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

Cache maintenance instructions do not count as events.
**0x02C, Attributable Level 3 data cache write-back**

The counter counts every Attributable write-back of data from the Level 3 data or unified cache. The counter counts each Attributable write-back that causes data to be written from the Level 3 cache to outside of the Level 3 cache. For example, the counter counts the following cases:

- An Attributable write-back of a recently fetched cache line that has not been allocated to the Level 3 cache.
- Transfer of data from the Level 3 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 3 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each Attributable write-back is counted once, even if multiple accesses are required to complete the write-back.

Whether this also includes Attributable write-backs made as a result of cache maintenance instructions is IMPLEMENTATION DEFINED.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 2 cache or memory.
- Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. Unattributable write-back events are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [*Attributability* on page D5-1856].

**0x02D, Attributable Level 2 data TLB refill**

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB refill of at least the Level 2 data or unified TLB. It counts each Attributable read or Attributable write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [*Attributability* on page D5-1856].
- *Relationship between REFILL events and associated access events* on page D5-1882.

**0x02E, Attributable Level 2 instruction TLB refill**

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 2 instruction TLB. This includes each Attributable instruction memory access that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [*Attributability* on page D5-1856].
- *Relationship between REFILL events and associated access events* on page D5-1882.
0x02F, Attributable Level 2 data or unified TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 data or unified TLB. Each access to a TLB record is counted, including the multiple accesses of instructions such as LDM or STM.

TLB maintenance instructions do not count as events.

See also Attributability on page D5-1856.

0x030, Attributable Level 2 instruction TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 instruction or unified TLB. TLB maintenance instructions do not count as events.

See also Attributability on page D5-1856.

D5.10.5 Relationship between REFILL events and associated access events

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table D5-7 shows this correspondence.

D5.10.6 Required events

PMUv3 requires that an implementation includes the following common events:

• 0x000, Instruction architecturally executed, condition code check pass, software increment.

• 0x003, Level 1 data cache refill.

_________ Note _________

Event 0x003 is only required if the implementation includes a Level 1 data or unified cache.

_________ Note _________

Event 0x004 is only required if the implementation includes a Level 1 data or unified cache.

• 0x004, Level 1 data cache access.

_________ Note _________

Event 0x004 is only required if the implementation includes a Level 1 data or unified cache.

• 0x010, Mispredicted or not predicted branch speculatively executed.
### Note

Event 0x010 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in *Common microarchitectural event numbers* on page D5-1873.

- 0x011, Cycle.
- 0x012, Predictable branch speculatively executed.

### Note

Event 0x012 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in *Common microarchitectural event numbers* on page D5-1873.

- At least one of:
  - 0x008, Instruction architecturally executed.
  - 0x01B, Operation speculatively executed.

### Note

ARM strongly recommends that event 0x008 is implemented.

#### D5.10.7 IMPLEMENTATION DEFINED event numbers

For IMPLEMENTATION DEFINED event numbers, each counter is defined, independently, to either:

- Increment only once for each event.
- Count the duration for which an event occurs.

ARM recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common count numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, ARM recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

ARM strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Cumulative duration of stalls resulting from the holes in the instruction availability, separating out counts for key buffering points that might exist.
- Cumulative duration of data-dependent stalls, separating out counts for key dependency classes that might exist.
- Cumulative duration of stalls due to unavailability of execution resources, including, for example, write buffers, separating out counts for key resources that might exist.
- Missed superscalar issue opportunities, if relevant, separating out counts for key classes of issue that might exist.
- Miss rates for different levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE.\{A, I, F\} interrupt mask set to 1.
- Any other microarchitectural features that the implementer considers are valuable to count.

The IMPLEMENTATION DEFINED event numbers are 0x040 to 0x3FF. *Appendix J3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events* lists the ARM recommended standardized numbering scheme for these events.
D5.11 Performance Monitors Extension registers

The following section describes the Performance Monitors Extension registers.

The following subsections give general information about the Performance Monitors Extension registers, that apply for both Execution states:

- Relationship between AArch32 and AArch64 Performance Monitors registers.
- Access permissions.

Performance Monitors Extension registers, functional group on page G4-4243 summarizes the Performance Monitors Extension registers in AArch32 state.

Instructions for accessing non-debug System registers on page C5-255 summarizes the Performance Monitors Extension registers in AArch64 state.

D5.11.1 Relationship between AArch32 and AArch64 Performance Monitors registers

Table J11-2 on page J11-5818 lists the Performance Monitors register names for AArch32 and AArch64 states.

D5.11.2 Access permissions

Each Exception level is able to control Performance Monitors system register accesses at lower Exception levels. The access control flow is:

1. At EL0:
   - Writes to PMUSERENR are UNDEFINED.
   - Reads and writes of PMINTENSET and PMINTENCLR are UNDEFINED.
   - If PMUSERENR.EN == 0:
     - If PMUSERENR.SW == 0 then writes to PMSWINC are trapped to EL1.
     - If PMUSERENR.CR == 0 then reads of PMCCNTR are trapped to EL1.
     - If PMUSERENR.ER == 0 then reads of PMEVCNTR<n> and PMXEVCNTR, and reads and writes of PMSELR, are trapped to EL1.
     - Otherwise, for all other Performance Monitors registers, other than reads of PMUSERENR, reads and writes are trapped to EL1.

   **Note**
   
   If HCR.TGE==1, then all exceptions that would be taken to EL1 are instead taken to EL2.

2. Otherwise, at EL1 and EL0 in Non-secure state, if EL2 is implemented:
   - If HDCR.TPMCR == 1 then accesses to PMCR are trapped to EL2.
   - If HDCR.TPM == 1 then accesses to all Performance Monitors registers, including PMCR, are trapped to EL2.

3. Otherwise, at EL2, EL1 and EL0, if EL3 is implemented and using AArch64, and if MDCR_EL3.TPM == 1 then accesses to all Performance Monitors registers are trapped to EL3.

   **Note**
   
   These traps are not possible if EL3 is using AArch32.

4. Otherwise, the access is permitted.

   **Note**
   
   These traps and enables only apply to System register accesses using system register access instructions. For accesses through the optional memory-mapped or external debug interfaces, see Access permissions for memory-mapped views of the Performance Monitors on page I2-5264.
For details of the headings used in Table D5-8, see Configurable instruction enables and disables, and trap controls on page D1-1558. In addition, the following terms are used:

**Instruction**
This shows the access instruction, read (MRS), write (MSR), or both (-). In AArch32 state, the equivalent instructions are MRC and MCR.

**Default access**
If the Default access is - then the access is trapped from EL0 to EL1 unless the PMUSERENR enables are set to 1.

**Resultant access permission**
This indicates the resulting access permission provided the enables at EL0 are enabled and the traps to EL2 or EL3 are disabled.

Table D5-8 shows the access permissions for system register accesses to the Performance Monitors system registers.

**Table D5-8 Access permissions for the Performance Monitors system registers**

<sup>a</sup> Only if EL3 is using AArch64.
D5.12 Pseudocode description

In AArch64 state, the pseudocode function for ProfilingProhibited() is as follows:

```plaintext
// AArch64.ProfilingProhibited()
// -----------------------------------------------
// Determine whether event counting is prohibited in the current state.

boolean AArch64.ProfilingProhibited(boolean secure, bits(2) el)
{
    // Events are always counted in Non-secure state.
    if (!secure) then return FALSE;

    // Event counting in Secure state is prohibited unless any one of:
    // * EL3 is not implemented
    if (!HaveEL(EL3)) then return FALSE;

    // * EL3 is using AArch64 and MDCR_EL3.SPME == 1
    if MDCR_EL3.SPME == '1' then return FALSE;

    // * Allowed by the IMPLEMENTATION DEFINED authentication interface
    if ExternalSecureNoninvasiveDebugEnabled() then return FALSE;

    return TRUE;
}
```

In AArch32 state, the function is as follows:

```plaintext
// AArch32.ProfilingProhibited()
// -----------------------------------------------
// Determine whether event counting is prohibited in the current state.

boolean AArch32.ProfilingProhibited(boolean secure, bits(2) el)
{
    if (el == EL0 && !ELUsingAArch32(EL1)) || !ELUsingAArch32(el) then
        return AArch64.ProfilingProhibited(secure, el);

    // Events are always counted in Non-secure state.
    if (!secure) then return FALSE;

    // Event counting in Secure state is prohibited unless any one of:
    // * EL3 is not implemented
    if !HaveEL(EL3) then return FALSE;

    // * EL3 is using AArch64 and MDCR_EL3.SPME == 1
    if MDCR_EL3.SPME == '1' then return FALSE;

    // * EL3 is using AArch32 and SDCR.SPME == 1
    spme = (if ELUsingAArch32(EL3) then SDCR.SPME else MDCR_EL3.SPME);
    if spme == '1' then return FALSE;

    // * Allowed by the IMPLEMENTATION DEFINED authentication interface
    if ExternalSecureNoninvasiveDebugEnabled() then return FALSE;

    // * EL3 or EL1 is using AArch32, executing at EL0, and SDER.SUNIDEN == 1.
    if el == EL0 && ELUsingAArch32(EL1) && SDER.SUNIDEN == '1' then return FALSE;

    return TRUE;
}
```

The CountEvents() function returns TRUE if PMNs counts events in the current mode and state. Note that this function does not completely describe the behavior for Unattributable events. In AArch64 state, the pseudocode function is as follows:

```plaintext
// AArch64.CountEvents()
// ........................
// Return TRUE if counter "n" should count its event.

boolean AArch64.CountEvents(integer n)
{
    assert(n == 31 || n < UInt(PMCR_EL0.N));
}
```
// Event counting is disabled in Debug state
debug = Halted();

// Event counting might be prohibited
prohibited = AArch64.ProfilingProhibited(IsSecure(), PSTATE.EL);
if prohibited && n == 31 && PMCR_EL0.DP == '0' then prohibited = FALSE;

// Event counting can be filtered by the (P, U, NSK, NSU, NSH) bits
filter = (if n == 31 then PMCCFILTR_EL0[31:26] else PMEVTYPER_EL0[n][31:26]);
M = if !HaveEL(EL3) then '0' else (filter<5> EOR filter<0>);
H = if !HaveEL(EL2) then '0' else filter<1>;
P = filter<5>;
U = P EOR filter<3>;
if !IsSecure() && HaveEL(EL3) then
  P = P EOR filter<3>;
  U = U EOR filter<2>;

case PSTATE.EL of
  when EL0      filtered = U == '1';
  when EL1,EL3  filtered = P == '1';
  when EL2      filtered = H == '0';
  when EL3      filtered = M == '1';
if HaveEL(EL2) then
  E = (if n < UInt(MDCR_EL2.HPMN) then PMCR_EL0.E else MDCR_EL2.HPME);
else
  E = PMCR_EL0.E;

enabled = (E == '1' && PMCNTENSET_EL0<n> == '1');
return !debug && !prohibited && !filtered && enabled;

In AArch32 state, the function is as follows:

// AArch32.CountEvents()
// =====================
// Return TRUE if counter "n" should count its event.

boolean AArch32.CountEvents(integer n)
assert(n == 31 || n < UInt(PMCR.N));
if !ELUsingAArch32(EL1) then return AArch64.CountEvents(n);

// Event counting is disabled in Debug state
ddebug = Halted();

// Event counting might be prohibited
prohibited = AArch32.ProfilingProhibited(IsSecure(), PSTATE.EL);
if prohibited && n == 31 && PMCR_EL0.DP == '0' then prohibited = FALSE;

// Event counting can be filtered by the (P, U, NSK, NSU, NSH) bits
filter = (if n == 31 then PMCCFILTR_EL0[31:26] else PMEVTYPER_EL0[n][31:26]);
H = if !HaveEL(EL2) then '0' else filter<1>;
P = filter<5>;
U = P EOR filter<3>;
if !IsSecure() && HaveEL(EL3) then
  P = P EOR filter<3>;
  U = U EOR filter<2>;

case PSTATE.EL of
  when EL0      filtered = U == '1';
  when EL1,EL3  filtered = P == '1';
  when EL2      filtered = H == '0';
if HaveEL(EL2) then
  hpmn = if !ELUsingAArch32(EL2) then MDCR_EL2.HPMN else HDCR.HPMN;
hpme = if !ELUsingAArch32(EL2) then MDCR_EL2.HPME else HDCR.HPME;
E = (if n < UInt(hpmn) then PMCR.E else hpme);
else
    E = PMCR.E;
enabled = (E == '1' && PMCNTENSET<n> == '1');
return !debug && !prohibited && !filtered && enabled;
Chapter D6
The Generic Timer in AArch64 state

This chapter describes the implementation of the ARM Generic Timer. It includes an overview of the AArch64 System register interface to an ARM Generic Timer.

It contains the following sections:
- About the Generic Timer in AArch64 state on page D6-1892.
- About the Generic Timer AArch64 System registers on page D6-1899.

Chapter I1 System Level Implementation of the Generic Timer describes the system level implementation of the Generic Timer.
D6.1 About the Generic Timer in AArch64 state

Figure D6-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The ARM Generic Interrupt Controller Architecture Specification defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.
- Supports virtual counters that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D6-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch64 state. Chapter G5 The Generic Timer in AArch32 state describes access to this component from AArch32 state.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D6-1
- Optionally, can provide timer components for use at a system level.

Chapter II System Level Implementation of the Generic Timer describes this memory-mapped component.
D6.1 System counter

The Generic Timer provides a system counter with the following specification:

**Width**
- At least 56 bits wide.
- The value returned by any 64-bit read of the counter is zero-extended to 64 bits.

**Frequency**
- Increments at a fixed frequency, typically in the range 1-50MHz.
- Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.

**Roll-over**
- Roll-over time of not less than 40 years.

**Accuracy**
- ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.
- Use of lower-frequency modes must not affect the implemented accuracy.

**Start-up**
- Starts operating from zero.

The system counter must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The **CNTFRQ_EL0** register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see Initializing and reading the system counter frequency.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a system control register interface to the system counter must have a counter input that can capture each increment of the counter.

--- Note ---

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. Gray-count scheme for timer distribution scheme on page I1-5262 gives more information about this possibility.

--- Initializing and reading the system counter frequency ---

The **CNTFRQ_EL0** register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System control register interface to write the system counter frequency to the **CNTFRQ_EL0** register. Only software executing at the highest implemented Exception level can write to **CNTFRQ_EL0**.

--- Note ---

The **CNTFRQ_EL0** register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.
Software can read the `CNTFRQ_EL0` register, to determine the current system counter frequency, in the following states:

- EL2.
- Secure and Non-secure EL1.
- When `CNTKCTL_EL1.EL0PCTEN` is set to 1, Secure and Non-secure EL0.

**Memory-mapped controls of the system counter**

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter 11 *System Level Implementation of the Generic Timer*.

**D6.1.2 The physical counter**

The PE includes a physical counter that contains the count value of the system counter. The `CNTPCT_EL0` register holds the current physical counter value.

**Accessing the physical counter**

Software with sufficient privilege can read `CNTPCT_EL0` using a 64-bit system control register read. `CNTPCT_EL0`:

- Is always accessible from EL3, Non-secure EL2 and Secure EL1 states.
- Is accessible from Non-secure EL1 only when `CNTHCTL_EL2.EL1PCTEN` is set to 1. When the value of `CNTHCTL_EL2.EL1PCTEN` is 0, any attempt to access `CNTPCT_EL0` from Non-secure EL1 is trapped to EL2.
- Is accessible from Secure EL0 state when the value of `CNTKCTL_EL1.EL0PCTEN` is 1. When the value of `CNTKCTL_EL1.EL0PCTEN` is 0, any attempt to access `CNTPCT_EL0` generates an UNDEFINED exception.
- Is accessible from Non-secure EL0 when the value of `CNTHCTL_EL2.EL1PCTEN` is 1 and the value of `CNTKCTL_EL1.EL0PCTEN` is 1. Otherwise:
  - When the value of `CNTKCTL_EL1.EL0PCTEN` is 0, any attempt to access `CNTPCT_EL0` from Non-secure EL0 generates an UNDEFINED exception.
  - When the value of `CNTKCTL_EL1.EL0PCTEN` is 1 and the value of `CNTHCTL_EL2.EL1PCTEN` is 0, any attempt to access `CNTPCT_EL0` from Non-secure EL0 is trapped to EL2.

Reads of `CNTPCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTPCT_EL0` must be read, an `ISB` must be used to ensure that the read of `CNTPCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]   ; without this, the CNTPCT could be read before the memory location in [R2]
    CMP R1, #1     ; has had the value 1 written to it
    BNE loop
    ISB            ; without this, the CNTPCT could be read before the memory location in [R2]
    MRS R1, CNTPCT
```
D6.1.3 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time:

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at Non-secure EL1 or EL0, the virtual offset value relates to the current virtual machine.

The `CNTVOFF_EL2` register contains the virtual offset. `CNTVOFF_EL2` is only accessible from EL2 and EL3.

For more information see Status of the CNTVOFF register on page D6-1899.

The `CNTVCT_EL0` register holds the current virtual counter value.

Accessing the virtual counter

Software with sufficient privilege can read `CNTVCT_EL0` using a 64-bit system control register read.

`CNTVCT_EL0` is always accessible from Secure EL3, from Secure EL1 when EL3 is using AArch64, and from Non-secure EL1 and EL2.

In addition, when `CNTKCTL_EL1.ELOVCTEN` is set to 1, `CNTVCT_EL0` is accessible from EL0.

When `CNTKCTL_EL1.ELOVCTEN` is set to 0, any attempt to access `CNTVCT_EL0` from EL0 is UNDEFINED.

Reads of `CNTVCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTVCT_EL0` must be read, an ISB must be used to ensure that the read of `CNTVCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop
    ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]
    CMP R1, #1
    BNE loop
    ISB             ; without this, the CNTVCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
    MRS R1, CNTVCT
```

D6.1.4 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more event streams, to generate periodic wake-up events as part of the mechanism described in Wait for Event mechanism and Send event on page D1-1595.

Note

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The `CNTKCTL_EL1.{EVNTEN, EVNTDIR, EVNTI}` fields define an event stream that is generated from the virtual counter.

In all implementations the `CNTKCTL_EL2.{EVNTEN, EVNTDIR, EVNTI}` fields define an event stream that is generated from the physical counter.
The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:
  ```
  // Variables used for generation of the timer event stream.
  bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
  bits(64) PreviousCNTPCT = bits(64) UNKNOWN;
  ```
- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():
The following sections describe:

- **Accessing the timer registers**
- **Operation of the CompareValue views of the timers**
- **Operation of the TimerValue views of the timers** on page D6-1898.

**Accessing the timer registers**

For each timer, all timer registers have the same access permissions, as follows:

**EL1 physical timer** Accessible from EL1, except that Non-secure software executing at EL2 controls access from Non-secure EL1.

When access from EL1 is permitted, CNTKCTL_EL1.EL0PTEN determines whether the registers are accessible from EL0. If an access is not permitted because CNTKCTL_EL1.EL0PTEN is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- Except for accesses from EL3, accesses are to the registers for the current Security state.
- For accesses from EL3, the value of SCR_EL3.NS determines whether accesses are to the Secure or the Non-secure registers.
- The Non-secure registers are accessible from EL2.
- CNTHCTL_EL2.EL1PCEN determines whether the Non-secure registers are accessible from Non-secure EL1. If this bit is set to 1, to enable access from Non-secure EL1, CNTKCTL_EL1.EL0PTEN determines whether the registers are accessible from Non-secure EL0.

If an access is not permitted because CNTHCTL_EL2.EL1PCEN is set to 0, an attempted access from a Non-secure EL1 or EL0 generates a Hyp Trap exception. However, if CNTKCTL_EL1.EL0PTEN is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED.

**Virtual timer** Accessible from Secure and Non-secure EL1, and from EL2.

CNTKCTL_EL1.EL0VTEN determines whether the registers are accessible from EL0. If an access is not permitted because CNTKCTL_EL1.EL0VTEN is set to 0, an attempted access from an EL0 is UNDEFINED.

**EL2 physical timer** Accessible from EL2, and from EL3 when SCR_EL3.NS is set to 1.

**Operation of the CompareValue views of the timers**

The CompareValue view of a timer operates as a 64-bit upcounter. The timer triggers when the appropriate counter reaches the value programmed into a CompareValue register. When the timer triggers, it generates an interrupt if the interrupt is enabled in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTPS_CTL_EL1, or CNTV_CTL_EL0. For CNTP_CTL_EL0, the asserted interrupt is the same as the interrupt asserted by the Non-secure instance of CNTP_CTL.

The operation of this view of a timer is:

\[
\text{EventTriggered} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) > 0)
\]

Where:

- **EventTriggered** Is TRUE if the event for this timer must be triggered, and FALSE otherwise.
- **Counter** The physical counter value, that can be read from the CNTPCT_EL0 register.

______ **Note** ________

The virtual counter value, that can be read from the CNTVCT_EL0 register, is the value:

\[
(\text{Counter} - \text{Offset})
\]
Offset For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the CNTVOFF_EL2 register.

CompareValue The value of the appropriate CompareValue register, CNTP_CV_AL_EL0, CNTHP_CV_AL_EL2, or CNTV_CV_AL_EL0.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

--- Note ---
This means that a timer with a CompareValue of, or close to, 0xFFFF_FFFF_FFFF_FFFF might never trigger. However, there is no practical requirement to use values close to the counter wrap value.

--- Operation of the TimerValue views of the timers ---

The TimerValue view of a timer operates as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer triggers when the value reaches zero. When the timer triggers, it generates an interrupt if the interrupt is enabled in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, or CNTV_CTL_EL0.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

**Reads**

\[
\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset}))[31:0]
\]

**Writes**

\[
\text{CompareValue} = ((\text{Counter} - \text{Offset})[63:0] + \text{SignExtend}(\text{TimerValue}))[63:0]
\]

Where the arguments have the definitions used in *Operation of the CompareValue views of the timers on page D6-1897*, and in addition:

TimerValue The value of a TimerValue register, CNTP_TV_AL_EL0, CNTHP_TV_AL_EL2, or CNTV_TV_AL_EL0.

--- Note ---

*Operation of the CompareValue views of the timers on page D6-1897* gives a strict definition of EventTriggered. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:

\[
\text{EventTriggered} = (\text{TimerValue} \leq 0)
\]

In this view of a timer, all values are signed, in standard two's complement form.

After an event has triggered, a read of a TimerValue register indicates the time since the event triggered.

--- Note ---

Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays the resultant interrupt for an extremely long period of time.
D6.2 About the Generic Timer AArch64 System registers

D6.2.1 Status of the CNTVOFF register

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF_EL2 register that defines the virtual offset between the physical count and the virtual count. CNTVOFF_EL2 is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.
D6.2 About the Generic Timer AArch64 System registers
Chapter D7
AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- About the AArch64 System registers on page D7-1902.
- General system control registers on page D7-1906.
- Debug registers on page D7-2152.
- Performance Monitors registers on page D7-2223.
- Generic Timer registers on page D7-2263.
- About the Generic Interrupt Controller (GIC) System registers on page D7-2292.
- Generic Interrupt Controller CPU interface System registers on page D7-2293.
- Generic Interrupt Controller Virtual interface control System registers on page D7-2349.
D7.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- Fixed values in the System register descriptions.
- General behavior of accesses to the System registers.

D7.1.1 Fixed values in the System register descriptions

See Fixed values in instruction and System register descriptions on page C5-242. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions.

D7.1.2 General behavior of accesses to the System registers

This section gives general information about the behavior of accesses to the System registers.

Synchronization requirements for System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that any data dependencies between the instructions are respected.

Note

In particular, system registers that hold self-incrementing counts such as the performance counters or the Generic Timer counter or timers, can be read early. For example, where a memory access is used to communicate a read of such counters, an ISB must be inserted between the read of the memory location and the read of the Generic Timer counter, where it is necessary that the Generic Timer counter returns a count value after the memory communication.

Direct writes using the instructions in Table C5-6 on page C5-256 require synchronization before software can rely on the effects of changes to the system registers to affect instructions appearing in program order after the direct write to the system register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- All direct writes to ICC_PMR_EL1.

Explicit synchronization occurs as a result of a Context synchronization operation, which is one of the following events:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Execution of a DCPS instruction in Debug state.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

Note

The ISB, exception entry, or exception return events are applicable either in Debug state or not in Debug state.

Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.
Note

This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of system registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

In addition, any system instructions that cause a write to a system register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that system register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- ISR_EL1.
- The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TVAL_EL0, CNTV_TVAL_EL0, CNTHP_TVAL_EL2, and CNTPS_TVAL_EL1.
- DBGCLAIMCLR_EL1.
- The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSSET_EL0.
- The Debug Communications Channel registers, that is, DBGDTRTX_EL0, DBGDTRRX_EL0, DBGDTR_EL0, and MDCCSR_EL0.

All other direct reads of system registers can occur in any order if synchronization has not been performed.

Table D7-1 describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

</tbody>
</table>
The terms Direct read, Direct write, Indirect read, and Indirect write, as used in Table D7-1 on page D7-1903, are defined as follows:

**Direct read**
Where software uses a system register access instruction to read the register, see both:
- Instructions for accessing non-debug System registers on page C5-255.
- Instructions for accessing debug System registers on page C5-253.

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

**Direct write**
Where software uses a system register access instruction to write to the register, see both:
- Instructions for accessing non-debug System registers on page C5-255.
- Instructions for accessing debug System registers on page C5-253.

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

**Indirect read**
Where an instruction uses a system register to establish operating conditions, for example, translation table base register addresses or whether the cache is enabled, for the instruction. This includes situations where the contents of one system register selects what value is read using a different register. Indirect reads also include reads of the system register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

**Indirect write**
Where a system register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

**Note**
Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.
Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in Table D7-2, are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

### Table D7-2 Registers with a guarantee of observability, VMSAv8-64

</tr>
<tr>
<td>EDSCR.PipeAdv</td>
<td>External Debug Status and Control Register PipeAdv field</td>
</tr>
</tbody>
</table>

In addition to the requirements shown in Table D7-2, when the PE is in Debug state, there are synchronization requirements for:

- The EDITR and ITR flags in EDSCR.
- DBGDTRTX_EL0, DBGDTRRX_EL0, and the DCC flags in EDSCR.

See DCC and ITR access in Debug state on page H4-5057.

**Note**

- The provision of explicit synchronization requirements to system registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.

- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.

- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.
D7.2 General system control registers

This section lists the system control registers in AArch64 that are not part of one of the other listed groups.
### D7.2.1 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TACR==1, Non-secure EL1 accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ACTLR_EL1[31:0] is architecturally mapped to AArch32 System register ACTLR.

AArch64 System register ACTLR_EL1[63:32] is architecturally mapped to AArch32 System register ACTLR2.

**Attributes**

ACTLR_EL1 is a 64-bit register.

**Field descriptions**

The ACTLR_EL1 bit assignments are:

![Field descriptions diagram]

**Accessing the ACTLR_EL1:**

To access the ACTLR_EL1:

MRS <Xt>, ACTLR_EL1 ; Read ACTLR_EL1 into Xt

MSR ACTLR_EL1, <Xt> ; Write Xt to ACTLR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.2 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register ACTLR_EL2[31:0] is architecturally mapped to AArch32 System register HACTLR.

AArch64 System register ACTLR_EL2[63:32] is architecturally mapped to AArch32 System register HACTLR2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

ACTLR_EL2 is a 64-bit register.

**Field descriptions**

The ACTLR_EL2 bit assignments are:

- IMPLEMENTATION DEFINED, bits [63:0]

**Accessing the ACTLR_EL2:**

To access the ACTLR_EL2:

MRS <Xt>, ACTLR_EL2 ; Read ACTLR_EL2 into Xt
MSR ACTLR_EL2, <Xt> ; Write Xt to ACTLR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0001</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.3 ACTLR_EL3, Auxiliary Control Register (EL3)

The ACTLR_EL3 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

ACTLR_EL3 is a 64-bit register.

**Field descriptions**

The ACTLR_EL3 bit assignments are:

- IMPLEMENTATION DEFINED, bits [63:0]

**Accessing the ACTLR_EL3:**

To access the ACTLR_EL3:

- MRS <Xt>, ACTLR_EL3 ; Read ACTLR_EL3 into Xt
- MSR ACTLR_EL3, <Xt> ; Write Xt to ACTLR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0001</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.4 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register AFSR0_EL1 is architecturally mapped to AArch32 System register ADFSR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

AFSR0_EL1 is a 32-bit register.

**Field descriptions**

The AFSR0_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>Field Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>
```

**Accessing the AFSR0_EL1:**

To access the AFSR0_EL1:

- MRS <Xt>, AFSR0_EL1 ; Read AFSR0_EL1 into Xt
- MSR AFSR0_EL1, <Xt> ; Write Xt to AFSR0_EL1

Register access is encoded as follows:

```
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0101</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
```
D7.2.5  AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0_EL2 characteristics are:

**Purpose**
Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**
There are no traps or enables affecting this register.

**Configurations**
AArch64 System register AFSR0_EL2 is architecturally mapped to AArch32 System register HADFSR.
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**
AFSR0_EL2 is a 32-bit register.

**Field descriptions**
The AFSR0_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>0</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

**Accessing the AFSR0_EL2:**
To access the AFSR0_EL2:

MRS <Xt>, AFSR0_EL2 ; Read AFSR0_EL2 into Xt
MSR AFSR0_EL2, <Xt> ; Write Xt to AFSR0_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0101</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.6 AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)

The AFSR0_EL3 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>

</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

**Accessing the AFSR0_EL3:**

To access the AFSR0_EL3:

MRS <Xt>, AFSR0_EL3 ; Read AFSR0_EL3 into Xt
MSR AFSR0_EL3, <Xt> ; Write Xt to AFSR0_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0101</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.7 AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1_EL1 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>

</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register AFSR1_EL1 is architecturally mapped to AArch32 System register AIFSR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

AFSR1_EL1 is a 32-bit register.

**Field descriptions**

The AFSR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td>30-0</td>
<td>IMPLEMENTATION DEFINED, bits [31:0]</td>
</tr>
</tbody>
</table>

**Accessing the AFSR1_EL1:**

To access the AFSR1_EL1:

- MRS <Xt>, AFSR1_EL1; Read AFSR1_EL1 into Xt
- MSR AFSR1_EL1, <Xt>; Write Xt to AFSR1_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

</tbody>
</table>
D7.2.8 AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1_EL2 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register AFSR1_EL2 is architecturally mapped to AArch32 System register HAIFSR.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

AFSR1_EL2 is a 32-bit register.

**Field descriptions**

The AFSR1_EL2 bit assignments are:

```
+-----------------------------------+--------+
| 31                               | 0      |
| IMPLEMENTATION DEFINED            |        |
+-----------------------------------+--------+
```

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

**Accessing the AFSR1_EL2:**

To access the AFSR1_EL2:

MRS <Xt>, AFSR1_EL2 ; Read AFSR1_EL2 into Xt
MSR AFSR1_EL2, <Xt> ; Write Xt to AFSR1_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>

<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.9 AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)

The AFSR1_EL3 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

AFSR1_EL3 is a 32-bit register.

Field descriptions

The AFSR1_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR1_EL3:

To access the AFSR1_EL3:

MRS <Xt>, AFSR1_EL3 ; Read AFSR1_EL3 into Xt
MSR AFSR1_EL3, <Xt> ; Write Xt to AFSR1_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>

<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED.
D7.2.10 AIDR_EL1, Auxiliary ID Register

The AIDR_EL1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED identification information.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

The value of this register must be interpreted in conjunction with the value of MIDR_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID1==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register AIDR_EL1 is architecturally mapped to AArch32 System register AIDR.

**Attributes**

AIDR_EL1 is a 32-bit register.

**Field descriptions**

The AIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

**Accessing the AIDR_EL1:**

To access the AIDR_EL1:

MRS <Xt>, AIDR_EL1 ; Read AIDR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>001</td>
<td>0000</td>
<td>0000</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.2.11 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

AMAIR_EL1 is permitted to be cached in a TLB.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register AMAIR_EL1[31:0] is architecturally mapped to AArch32 System register AMAIR0.

AArch64 System register AMAIR_EL1[63:32] is architecturally mapped to AArch32 System register AMAIR1.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

AMAIR_EL1 is a 64-bit register.

**Field descriptions**

The AMAIR_EL1 bit assignments are:

```
+-------------------+-------------------+-------------------+-------------------+-------------------+
| 63               | 62               | 31               | 0                 |
| IMPLEMENTATION DEFINED | IMPLEMENTATION DEFINED | IMPLEMENTATION DEFINED |
+-------------------+-------------------+-------------------+-------------------+
```

**Accessing the AMAIR_EL1:**

To access the AMAIR_EL1:

MRS <Xt>, AMAIR_EL1 ; Read AMAIR_EL1 into Xt
MSR AMAIR_EL1, <Xt> ; Write Xt to AMAIR_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1010</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.12 AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR_EL2 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

AMAIR_EL2 is permitted to be cached in a TLB.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register AMAIR_EL2[31:0] is architecturally mapped to AArch32 System register HAMAIR0.

AArch64 System register AMAIR_EL2[63:32] is architecturally mapped to AArch32 System register HAMAIR1.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

AMAIR_EL2 is a 64-bit register.

**Field descriptions**

The AMAIR_EL2 bit assignments are:

![Field assignments](image)

**Accessing the AMAIR_EL2:**

To access the AMAIR_EL2:

MRS <Xt>, AMAIR_EL2 ; Read AMAIR_EL2 into Xt
MSR AMAIR_EL2, <Xt> ; Write Xt to AMAIR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1010</td>
<td>0011</td>
<td>000</td>

</tbody>
</table>
D7.2.13 AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)

The AMAIR_EL3 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

AMAIR_EL3 is permitted to be cached in a TLB.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

AMAIR_EL3 is a 64-bit register.

**Field descriptions**

The AMAIR_EL3 bit assignments are:

![Field descriptions diagram](image)

**Accessing the AMAIR_EL3:**

To access the AMAIR_EL3:

MRS <Xt>, AMAIR_EL3 ; Read AMAIR_EL3 into Xt
MSR AMAIR_EL3, <Xt> ; Write Xt to AMAIR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1010</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
### D7.2.14 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

If CSSEL_EL1.Level indicates a cache that is not implemented, then on a read of the CCSIDR_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID2==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register CCSIDR_EL1 is architecturally mapped to AArch32 System register CCSIDR.

The implementation includes one CCSIDR_EL1 for each cache that it can access. CSSEL_EL1 selects which Cache Size ID Register is accessible.

**Attributes**

CCSIDR_EL1 is a 32-bit register.

**Field descriptions**

The CCSIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>WT</th>
<th>WB</th>
<th>RA</th>
<th>WA</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumSets</td>
<td>Associativity</td>
<td>LineSize</td>
<td></td>
</tr>
</tbody>
</table>

**WT, bit [31]**

Indicates whether the selected cache level supports write-through. Permitted values are:

- 0: Write-through not supported.
- 1: Write-through supported.
WB, bit [30]
Indicates whether the selected cache level supports write-back. Permitted values are:
0  Write-back not supported.
1  Write-back supported.

RA, bit [29]
Indicates whether the selected cache level supports read-allocation. Permitted values are:
0  Read-allocation not supported.
1  Read-allocation supported.

WA, bit [28]
Indicates whether the selected cache level supports write-allocation. Permitted values are:
0  Write-allocation not supported.
1  Write-allocation supported.

NumSets, bits [27:13]
(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets
does not have to be a power of 2.

Associativity, bits [12:3]
(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity
does not have to be a power of 2.

LineSize, bits [2:0]
(Log₂(Number of bytes in cache line)) - 4. For example:
For a line length of 16 bytes: \( \log_2(16) = 4 \), LineSize entry = 0. This is the minimum line length.
For a line length of 32 bytes: \( \log_2(32) = 5 \), LineSize entry = 1.

Note
The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters
that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual
microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on
these parameters.

Accessing the CCSIDR_EL1:
To access the CCSIDR_EL1:
MRS <Xt>, CCSIDR_EL1 ; Read CCSIDR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>001</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.15 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

**Purpose**

Identifies the type of cache, or caches, implemented at each level, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization](#) on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID2==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register CLIDR_EL1 is architecturally mapped to AArch32 System register CLIDR.

**Attributes**

CLIDR_EL1 is a 64-bit register.

**Field descriptions**

The CLIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>32</td>
<td>ICB</td>
</tr>
<tr>
<td>30-29</td>
<td>LoU</td>
</tr>
<tr>
<td>27-26</td>
<td>LoC</td>
</tr>
<tr>
<td>24-21</td>
<td>LoUIS</td>
</tr>
<tr>
<td>20-18</td>
<td>Ctype7</td>
</tr>
<tr>
<td>17-15</td>
<td>Ctype6</td>
</tr>
<tr>
<td>14-12</td>
<td>Ctype5</td>
</tr>
<tr>
<td>11-9</td>
<td>Ctype4</td>
</tr>
<tr>
<td>8-6</td>
<td>Ctype3</td>
</tr>
<tr>
<td>5-3</td>
<td>Ctype2</td>
</tr>
<tr>
<td>2-0</td>
<td>Ctype1</td>
</tr>
</tbody>
</table>

**Bits [63:33]**

Reserved, RES0.

**ICB, bits [32:30]**

Inner cache boundary. This field indicates the boundary between the inner and the outer domain.

The possible values are:

000  Not disclosed in this mechanism.
001  L1 cache is the highest inner level.
010  L2 cache is the highest inner level.
011  L3 cache is the highest inner level.
100  L4 cache is the highest inner level.
101  L5 cache is the highest inner level.
110  L6 cache is the highest inner level.
111  L7 cache is the highest inner level.
LoUU, bits [29:27]
   Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]
   Level of Coherence for the cache hierarchy.

LoUIS, bits [23:21]
   Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7
   Cache Type fields. Indicate the type of cache implemented at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:
   000  No cache.
   001  Instruction cache only.
   010  Data cache only.
   011  Separate instruction and data caches.
   100  Unified cache.
   All other values are reserved.

   If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR_EL1:

   To access the CLIDR_EL1:

   MRS <Xt>, CLIDR_EL1 ; Read CLIDR_EL1 into Xt

   Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

D7.2.16 CONTEXTIDR_EL1, Context ID Register

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.

If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

Configurations

AArch64 System register CONTEXTIDR_EL1 is architecturally mapped to AArch32 System register CONTEXTIDR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

CONTEXTIDR_EL1 is a 32-bit register.

Field descriptions

The CONTEXTIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>PROCID, bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process Identifier. This field must be programmed with a unique value that identifies the current process. The bottom 8 bits of this register are not used to hold the ASID.</td>
</tr>
</tbody>
</table>

Accessing the CONTEXTIDR_EL1:

To access the CONTEXTIDR_EL1:

MRS <Xt>, CONTEXTIDR_EL1; Read CONTEXTIDR_EL1 into Xt
MSR CONTEXTIDR_EL1, <Xt>; Write Xt to CONTEXTIDR_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1101</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.17  **CPACR_EL1, Architectural Feature Access Control Register**

The CPACR_EL1 characteristics are:

**Purpose**

Controls access to Trace, Floating-point, and Advanced SIMD functionality.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If `CPTR_EL2.TCPAC==1`, Non-secure EL1 accesses to this register are trapped to EL2.
- If `CPTR_EL3.TCPAC==1`, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register CPACR_EL1 is architecturally mapped to AArch32 System register CPACR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CPACR_EL1 is a 32-bit register.

**Field descriptions**

The CPACR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31 29 28 27</th>
<th>22 21 20 19</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RES0</td>
<td>FPEN</td>
</tr>
</tbody>
</table>

**TTA**

Reserved, RES0.

**Bits [31:29]**

Reserved, RES0.

**TTA, bit [28]**

Traps EL0 and EL1 System register accesses to all implemented trace registers to EL1, from both Execution states.

- 0  EL0 and EL1 System register accesses to all implemented trace registers are not trapped to EL1.
- 1  EL0 and EL1 System register accesses to all implemented trace registers are trapped to EL1.

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than a CPACR_EL1.TTA exception.
• The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If system register access to the trace functionality is not implemented, this bit is RES0.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps EL0 and EL1 accesses to the SIMD and floating-point registers to EL1, from both Execution states.

00 Causes any instructions in EL0 or EL1 that use the registers associated with floating-point and Advanced SIMD execution to be trapped.
01 Causes any instructions in EL0 that use the registers associated with floating-point and Advanced SIMD execution to be trapped, but does not cause any instruction in EL1 to be trapped.
10 Causes any instructions in EL0 or EL1 that use the registers associated with floating-point and Advanced SIMD execution to be trapped.
11 Does not cause any instruction to be trapped.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR_EL1:

To access the CPACR_EL1:

MRS <Xt>, CPACR_EL1 ; Read CPACR_EL1 into Xt
MSR CPACR_EL1, <Xt> ; Write Xt to CPACR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>001</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.18  CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of access to CPACR, CPACR_EL1, Trace functionality and registers associated with floating-point and Advanced SIMD execution. Also controls EL2 access to this functionality.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If CPTR_EL3.TCPAC==1, EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register CPTR_EL2 is architecturally mapped to AArch32 System register HCPTR.

- If EL2 is not implemented, this register is RES0 from EL3.
- RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

CPTR_EL2 is a 32-bit register.

Field descriptions

The CPTR_EL2 bit assignments are:

TCPAC, bit [31]

Traps Non-secure EL1 accesses to the CPACR_EL1 or CPACR to EL2, from both Execution states.

- 0 Non-secure EL1 accesses to the CPACR_EL1 or CPACR are not trapped to EL2.
- 1 Non-secure EL1 accesses to the CPACR_EL1 or CPACR are trapped to EL2.

Note

The CPACR_EL1 or CPACR is not accessible at EL0.

Bits [30:21]

Reserved, RES0.
TTA, bit [20]

Traps Non-secure System register accesses to the trace registers to EL2, from both Execution states.

0  Non-secure System register accesses to the trace registers are not trapped to EL2.
1  Any attempt at EL2, or Non-secure EL0 or EL1, to execute a System register access to a trace register is trapped to EL2.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than a CPTR_EL2.TTA Trap exception.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

Bits [19:14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps Non-secure accesses to SIMD and floating-point registers to EL2, from both Execution states.

0  Does not cause any instruction to be trapped.
1  Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2.

Bits [9:0]

Reserved, RES1.

Accessing the CPTR_EL2:

To access the CPTR_EL2:

MRS <Xt>, CPTR_EL2 ; Read CPTR_EL2 into Xt
MSR CPTR_EL2, <Xt> ; Write Xt to CPTR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.19  **CPTR_EL3, Architectural Feature Trap Register (EL3)**

The CPTR_EL3 characteristics are:

**Purpose**

Controls trapping to EL3 of access to CPACR_EL1, CPTR_EL2, Trace functionality and registers associated with floating-point and Advanced SIMD execution. Also controls EL3 access to Trace functionality and registers associated with floating-point and Advanced SIMD execution.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CPTR_EL3 is a 32-bit register.

**Field descriptions**

The CPTR_EL3 bit assignments are:

```
  31 30  21 20 19  11 10  9  0
TCPAC  RES0    RES0    RES0  TTA  TFP
```

**TCPAC, bit [31]**

Traps all of the following to EL3, from both Security states and both Execution states.

- EL2 accesses to the CPTR_EL2 or HCPTR.
- EL2 and EL1 accesses to the CPACR_EL1 or CPACR.

When CPTR_EL3.TCPAC is:

- 0  EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are not trapped to EL3.
- 1  EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3.

**Bits [30:21]**

Reserved, RES0.

**TTA, bit [20]**

Traps System register accesses to the trace registers, from all Exception levels, both Security states, and both Execution states, to EL3.

- 0  Does not cause any instruction to be trapped.
All System register accesses to the trace registers are trapped to EL3.
If System register access to trace functionality is not supported, this bit is RES0.

**Bits [19:11]**
Reserved, RES0.

**TFP, bit [10]**
Traps all accesses to SIMD and floating-point registers, from all Exception levels, both Security states, and both Execution states, to EL3.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Does not cause any instruction to be trapped.</td>
</tr>
<tr>
<td>1</td>
<td>Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3.</td>
</tr>
</tbody>
</table>

**Bits [9:0]**
Reserved, RES0.

### Accessing the CPTR_EL3:

To access the CPTR_EL3:

```assembly
MRS <Xt>, CPTR_EL3 ; Read CPTR_EL3 into Xt
MSR CPTR_EL3, <Xt> ; Write Xt to CPTR_EL3
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0001</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.20 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

**Purpose**

Selects the current Cache Size ID Register, CCSIDR_EL1, by specifying the required cache level and the cache type (either instruction or data cache).

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR_EL1.{Level, InD}.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID2==1, Non-secure EL1 accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register CSSELR_EL1 is architecturally mapped to AArch32 System register CSSELR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CSSELR_EL1 is a 32-bit register.

**Field descriptions**

The CSSELR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RES0</td>
<td></td>
<td>Level</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**Level, bits [3:1]**

Cache level of required cache. Permitted values are:

| 000 | Level 1 cache |
| 001 | Level 2 cache |
| 010 | Level 3 cache |
| 011 | Level 4 cache |
| 100 | Level 5 cache |
| 101 | Level 6 cache |
110  Level 7 cache
All other values are reserved.

**InD, bit [0]**
Instruction not Data bit. Permitted values are:
0  Data or unified cache.
1  Instruction cache.

**Accessing the CSSELR_EL1:**
To access the CSSELR_EL1:

MRS <Xt>, CSSELR_EL1 ; Read CSSELR_EL1 into Xt
MSR CSSELR_EL1, <Xt> ; Write Xt to CSSELR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>010</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.21 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

**Purpose**

Provides information about the architecture of the caches.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TID2==1, Non-secure EL0 and EL1 read accesses to this register are trapped to EL2.
- If SCTLR_EL1.UCT==0, EL0 read accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register CTR_EL0 is architecturally mapped to AArch32 System register CTR.

**Attributes**

CTR_EL0 is a 32-bit register.

**Field descriptions**

The CTR_EL0 bit assignments are:

```
 31 30 28 27 24 23 20 19 16 15 14 13  4  3  0
 RES0  CWG  ERG  DminLine  L1Ip  RES0  IminLine
 RES1

Bit [31]

Reserved, RES1.

Bits [30:28]

Reserved, RES0.

CWG, bits [27:24]

Cache Writeback Granule. \( \log_2 \) of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of 0b0000 indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.
ERG, bits [23:20]

Exclusives Reservation Granule. $\log_2$ of the number of words of the maximum size of the
reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive
instructions.

A value of $0b0000$ indicates that this register does not provide Exclusives Reservation Granule
information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than $0b1001$ are reserved.

DminLine, bits [19:16]

$\log_2$ of the number of words in the smallest cache line of all the data caches and unified caches that
are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction
cache. Possible values of this field are:

- 01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- 10 Virtual Index, Physical Tag (VIPT)
- 11 Physical Index, Physical Tag (PIPT)

Other values are reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

$\log_2$ of the number of words in the smallest cache line of all the instruction caches that are
controlled by the PE.

Accessing the CTR_EL0:

To access the CTR_EL0:

MRS <Xt>, CTR_EL0 ; Read CTR_EL0 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>01</td>
<td>0000</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.22 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 DACR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register DACR32_EL2 is architecturally mapped to AArch32 System register DACR.

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

DACR32_EL2 is a 32-bit register.

**Field descriptions**

The DACR32_EL2 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| D15| D14| D13| D12| D11| D10| D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |

D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

00  No access. Any access to the domain generates a Domain fault.
01  Client. Accesses are checked against the permission bits in the translation tables.
11  Manager. Accesses are not checked against the permission bits in the translation tables.

The value 10 is reserved.

**Accessing the DACR32_EL2:**

To access the DACR32_EL2:

MRS <Xt>, DACR32_EL2 ; Read DACR32_EL2 into Xt
MSR DACR32_EL2, <Xt> ; Write Xt to DACR32_EL2
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0011</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.23 DCZID_EL0, Data Cache Zero ID register

The DCZID_EL0 characteristics are:

**Purpose**

Indicates the block size that is written with byte values of 0 by the DC ZVA (Data Cache Zero by Address) system instruction.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

There are no configuration notes.

**Attributes**

DCZID_EL0 is a 32-bit register.

**Field descriptions**

The DCZID_EL0 bit assignments are:

\[
\begin{array}{cccccc}
31 & 30 & 5 & 4 & 3 & 0 \\
\hline
\text{RES0} & & & & & \\
\hline
\text{BS} & & & & & \\
\hline
\text{DZP} & & & & & \\
\end{array}
\]

**Bits [31:5]**

Reserved, RES0.

**DZP, bit [4]**

Data Zero prohibited. Permitted values are:

- 0: DC ZVA instruction is permitted.
- 1: DC ZVA instruction is prohibited.

The value read from this field is governed by the access state and the values of the HCR_EL2.TDZ and SCTLR_EL1.DZE bits.

**BS, bits [3:0]**

Log2 of the block size in words. The maximum size supported is 2KB (value == 9).

**Accessing the DCZID_EL0:**

To access the DCZID_EL0:

MRS <Xt>, DCZID_EL0 ; Read DCZID_EL0 into Xt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0000</td>
<td>0000</td>
<td>111</td>
</tr>
</tbody>
</table>
ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL1.

See also *Exception classes and the ESR_ELx syndrome registers* on page D1-1520.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ESR_EL1 is made UNKNOWN as a result of an exception return from EL1.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.

If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ESR_EL1 is architecturally mapped to AArch32 System register DFSR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

ESR_EL1 is a 32-bit register.

**Field descriptions**

See ESR_ELx.

**Accessing the ESR_EL1:**

To access the ESR_EL1:

MRS <Xt>, ESR_EL1 ; Read ESR_EL1 into Xt

MSR ESR_EL1, <Xt> ; Write Xt to ESR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0101</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.25 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL2.

See also *Exception classes and the ESR_ELx syndrome registers* on page D1-1520.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an **UNPREDICTABLE** instruction is treated as **UNDEFINED**, and the exception is taken to EL2, the value of ESR_EL2 is **UNKNOWN**. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not **UNPREDICTABLE** at that Exception level, in order to avoid the possibility of a privilege violation.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register ESR_EL2 is architecturally mapped to AArch32 System register HSR.

If EL2 is not implemented, this register is **RES0** from EL3.

RW fields in this register reset to **IMPLEMENTATION DEFINED** values that might be **UNKNOWN**.

**Attributes**

ESR_EL2 is a 32-bit register.

**Field descriptions**

See ESR_ELx.

**Accessing the ESR_EL2:**

To access the ESR_EL2:

MRS <Xt>, ESR_EL2 ; Read ESR_EL2 into Xt
MSR ESR_EL2, <Xt> ; Write Xt to ESR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0101</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.26  **ESR_EL3, Exception Syndrome Register (EL3)**

The ESR_EL3 characteristics are:

**Purpose**

Holds syndrome information for an exception taken to EL3.

See also *Exception classes and the ESR_ELx syndrome registers* on page D1-1520.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ESR_EL3 is made UNKNOWN as a result of an exception return from EL3.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL3, the value of ESR_EL3 is UNKNOWN. The value written to ESR_EL3 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

ESR_EL3 is a 32-bit register.

**Field descriptions**

See ESR_ELx.

**Accessing the ESR_EL3:**

To access the ESR_EL3:

MRS <Xt>, ESR_EL3 ; Read ESR_EL3 into Xt
MSR ESR_EL3, <Xt> ; Write Xt to ESR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0101</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.27  ESR_ELx, Exception Syndrome Register (ELx)

This page describes ESR_EL1, ESR_EL2, and ESR_EL3.

The ESR_ELx characteristics are:

**Purpose**

Holds syndrome information for an exception taken to ELx.

See also *Exception classes and the ESR_ELx syndrome registers* on page D1-1520.

**Usage constraints**

ESR_ELx is made UNKNOWN as a result of an exception return from ELx.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to ELx, the value of ESR_ELx is UNKNOWN. The value written to ESR_ELx must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

If EL2 is not implemented, ESR_EL2 is RES0 from EL3.

**Attributes**

The ESR_ELx registers are 32-bit registers.

**Field descriptions**

The ESR_ELx bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>26 25 24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EC</td>
<td>IL</td>
</tr>
</tbody>
</table>

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

**EC == 000000, Exceptions with an unknown reason**

This value is valid for all described registers.

Unknown or Uncategorized Reason - generally used for exceptions as a result of erroneous execution.

See ISS encoding for exceptions with an unknown reason.

**EC == 000001, Exception from a WFI or WFE instruction**

This value is valid for all described registers.

Exceptions from WFE or WFI from either AArch32 or AArch64 as a result of configurable traps, enables, or disables.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See ISS encoding for an exception from a WFI or WFE instruction.
EC == 000011, Exception from an MCR or MRC access
This value is valid for all described registers.
Exceptions from MCR/MRC to CP15 from AArch32 as a result of configurable traps, enables, or disables that do not use code 0b000000.
See ISS encoding for an exception from an MCR or MRC access.

EC == 000100, Exception from an MCRR or MRRC access
This value is valid for all described registers.
Exceptions from MCRR/MRRC to CP15 from AArch32 as a result of configurable traps, enables, or disables that do not use code 0b000000.
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 000101, Exception from an MCR or MRC access
This value is valid for all described registers.
Exceptions from MCR/MRC to CP14 from AArch32 as a result of configurable traps, enables, or disables.
0b000000.
See ISS encoding for an exception from an MCR or MRC access.

EC == 000110, Exception from an LDC or STC access to CP14
This value is valid for all described registers.
Exceptions from LDC/STC to CP14 from AArch32 as a result of configurable traps, enables, or disables.
The only architected uses of these instructions to access CP14 are:
• An STC to write to DBGDTRRX_EL0 or DBGDTRRXInt.
• An LDC to read from DBGDTRTX_EL0 or DBGDTRTXInt.
See ISS encoding for an exception from an LDC or STC access to CP14.

EC == 000111, Exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP
This value is valid for all described registers.
Exceptions from an access to an Advanced SIMD or floating-point register as a result of CPACR_EL1.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP.
Excludes exceptions resulting from an HCR_EL2.TGE value of 1 that are reported with EC value 0b000000 as described in EC encodings when routing exceptions to EL2 on page D1-1531.
See ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP.

EC == 001000, Exception from an MCR or MRC access
This value is valid for ESR_EL2.
Exceptions from MRC (or VMRS) to CP10 for MVFR0, MVFR1, MVFR2, or FPSID as a result of ID Group traps from AArch32 unless reported using code 0b000111.
See ISS encoding for an exception from an MCR or MRC access.

EC == 001100, Exception from an MCRR or MRRC access
This value is valid for all described registers.
Exceptions from MCRR/MRRC to CP14 from AArch32 as a result of configurable traps, enables, or disables.
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 001110, Exception from an Illegal execution state, or a PC or SP alignment fault
This value is valid for all described registers.
Exceptions that occur because the value of PSTATE.IL is 1.
See ISS encoding for an exception from an Illegal execution state, or a PC or SP alignment fault.

EC == 010001, Exception from HVC or SVC instruction execution
This value is valid for ESR_EL1 and ESR_EL2.
SVC executed in AArch32 state.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.

See ISS encoding for an exception from HVC or SVC instruction execution.

**EC == 010010, Exception from HVC or SVC instruction execution**

This value is valid for ESR_EL2.

HVC that is not disabled executed in AArch32 state.

See ISS encoding for an exception from HVC or SVC instruction execution.

**EC == 010011, Exception from SMC instruction execution in AArch32 state**

This value is valid for ESR_EL2 and ESR_EL3.

SMC that is not disabled executed in AArch32 state.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

See ISS encoding for an exception from SMC instruction execution in AArch32 state.

**EC == 010101, Exception from HVC or SVC instruction execution**

This value is valid for all described registers.

SVC executed in AArch64 state.

See ISS encoding for an exception from HVC or SVC instruction execution.

**EC == 010110, Exception from HVC or SVC instruction execution**

This value is valid for all described registers.

HVC that is not disabled executed in AArch64 state.

See ISS encoding for an exception from HVC or SVC instruction execution.

**EC == 010111, Exception from SMC instruction execution in AArch64 state**

This value is valid for ESR_EL2 and ESR_EL3.

SMC that is not disabled executed in AArch64 state.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

See ISS encoding for an exception from SMC instruction execution in AArch64 state.

**EC == 011000, Exception from MSR, MRS, or System instruction execution in AArch64 state**

This value is valid for all described registers.

Exceptions from MSR, MRS, or System AArch64 instructions as a result of configurable traps, enables, or disables, except those reported using EC values 000000, 000001, or 000111.

This include all instructions that cause exceptions that are part of the encoding space defined in System instruction class encoding overview on page C5-245, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

See ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state.

**EC == 011111, IMPLEMENTATION DEFINED exception to EL3**

This value is valid for ESR_EL3.

Reserved for IMPLEMENTATION DEFINED exceptions to EL3.

See ISS encoding for a IMPLEMENTATION DEFINED exception to EL3.

**EC == 100000, Exception from an Instruction abort**

This value is valid for all described registers.

Instruction Abort that caused entry from a lower Exception level, where that Exception level could be using AArch64 or using AArch32.

Used for MMU faults generated by instruction accesses and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

See ISS encoding for an exception from an Instruction abort.

**EC == 100001, Exception from an Instruction abort**

This value is valid for all described registers.
Instruction Abort from the current Exception level, where the current Exception level must be using AArch64.
Used for MMU faults generated by instruction accesses and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from an Instruction abort.

EC == 100010, Exception from an Illegal execution state, or a PC or SP alignment fault
This value is valid for all described registers.
PC alignment fault.
See ISS encoding for an exception from an Illegal execution state, or a PC or SP alignment fault.

EC == 100000, Exception from a Data abort
This value is valid for all described registers.
Data Abort that caused entry from a lower Exception level, where that Exception level could be using AArch64 or using AArch32.
Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from a Data abort.

EC == 100101, Exception from a Data abort
This value is valid for all described registers.
Data Abort that caused entry from a current Exception level, where the current Exception level must be using AArch64.
Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
See ISS encoding for an exception from a Data abort.

EC == 100110, Exception from an Illegal execution state, or a PC or SP alignment fault
This value is valid for all described registers.
SP alignment fault.
See ISS encoding for an exception from an Illegal execution state, or a PC or SP alignment fault.

EC == 101000, Exception from a trapped Floating-point exception
This value is valid for ESR_EL1 and ESR_EL2.
Exceptions as a result of Floating-point exception from AArch32.
Whether this Exception class is supported is IMPLEMENTATION DEFINED.
See ISS encoding for an exception from a trapped Floating-point exception.

EC == 101100, Exception from a trapped Floating-point exception
This value is valid for all described registers.
Exceptions as a result of Floating-point exception from AArch64.
Whether this Exception class is supported is IMPLEMENTATION DEFINED.
See ISS encoding for an exception from a trapped Floating-point exception.

EC == 101111, SError interrupt
This value is valid for all described registers.
SError Interrupt.
See ISS encoding for an SError interrupt.

EC == 110000, Exception from a Breakpoint or Vector Catch debug event
This value is valid for ESR_EL1 and ESR_EL2.
Breakpoint debug event that caused entry from a lower Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug event.
EC == 110001, Exception from a Breakpoint or Vector Catch debug event
This value is valid for ESR_EL1 and ESR_EL2.
Breakpoint debug event from the current Exception level.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug event.

EC == 110010, Exception from a Software Step debug event
This value is valid for ESR_EL1 and ESR_EL2.
Software step debug event that caused entry from a lower Exception level.
See ISS encoding for an exception from a Software Step debug event.

EC == 110011, Exception from a Software Step debug event
This value is valid for ESR_EL1 and ESR_EL2.
Software step debug event from the current Exception level.
See ISS encoding for an exception from a Software Step debug event.

EC == 110100, Exception from a Watchpoint debug event
This value is valid for ESR_EL1 and ESR_EL2.
Watchpoint debug event that caused entry from a lower Exception level.
See ISS encoding for an exception from a Watchpoint debug event.

EC == 110101, Exception from a Watchpoint debug event
This value is valid for ESR_EL1 and ESR_EL2.
Watchpoint debug event from the current Exception level.
See ISS encoding for an exception from a Watchpoint debug event.

EC == 111000, Exception from execution of a Software Breakpoint instruction
This value is valid for ESR_EL1 and ESR_EL2.
BKPT instruction executed in AArch32 state.
See ISS encoding for an exception from execution of a Software Breakpoint instruction.

EC == 111010, Exception from a Breakpoint or Vector Catch debug event
This value is valid for ESR_EL2.
AArch32 state Vector catch debug event.
The only case where an exception from a Vector catch debug event is taken to an
Exception level that is using AArch64 is when the Vector catch is routed to EL2 and
EL2 is using AArch64.
See ISS encoding for an exception from a Breakpoint or Vector Catch debug event.

EC == 111100, Exception from execution of a Software Breakpoint instruction
This value is valid for all described registers.
BRK instruction executed in AArch64 state.
This is reported in ESR_EL3 only if a BRK instruction is executed at EL3.
See ISS encoding for an exception from execution of a Software Breakpoint instruction.

Other values are reserved.

IL, bit [25]
Instruction Length for synchronous exceptions. Possible values of this bit are:
0  16-bit instruction trapped.
1  32-bit instruction trapped. This value is also used when the exception is one of the
   following:
   • An SError interrupt.
   • An Instruction Abort exception.
   • A PC alignment fault exception.
   • An SP alignment fault exception.
   • A Data Abort exception for which the value of the ISV bit is 0.
   • An Illegal execution state exception.
• Any debug exception except for Software Breakpoint instruction exceptions. For Software Breakpoint instruction exceptions, this bit has its standard meaning:
  0 16-bit T32 BKPT instruction.
  1 32-bit A32 BKPT instruction or A64 BRK instruction.
• An exception reported using EC value 0b000000.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number, even if the reported exception was taken from AArch32 state. If the register number is AArch32 register R15, then:
  • If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
  • If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
    — The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
    — The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

The following subsections describe each ISS format.

ISS encoding for exceptions with an unknown reason

This encoding is used by Unknown or Uncategorized Reason - generally used for exceptions as a result of erroneous execution.

The ISS encoding for these exceptions is:

```
Bits [24:0]  
24 0  
|     |
| RES0|
```

Bits [24:0]

Reserved, RES0.

An exception with an unknown reason occurs in the following situations:
  • The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
    — A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
    — A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
    — Instruction encodings for instructions not implemented in the implementation.
  • In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
  • In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
  • In AArch32 state, attempted execution of a short vector floating-point instruction.
• An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.

• Attempted execution of:
  — An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  — An SMC instruction when disabled by SCR_EL3.SMD.
  — An HLT instruction when disabled by EDSCR.HDE.

• Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.

• Attempted execution, in Debug state, of:
  — A DCPS1 instruction in Non-secure state from EL0 when the value of HCR_EL2.TGE is 1.
  — A DCPS2 instruction from EL1 or EL0 when the value of SCR_EL3.NS is 0, or when EL2 is not implemented.
  — A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.

• When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.

• In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

• In AArch32 state, the attempted execution of an MRS (Banked register) or an MSR (Banked register) instruction to SPSR_mon, SP_mon, or LR_mon.

• An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0b000111.

**ISS encoding for an exception from a WFI or WFE instruction**

This encoding is used by Exceptions from WFE or WFI from either AArch32 or AArch64 as a result of configurable traps, enables, or disables.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

The ISS encoding for these exceptions is:

```
   24 23 20 19   1  0
   COND  RES0  Ti
```

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.
For exceptions taken from AArch64, this field is set to $0b1110$.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to $0b1110$.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to $0b1110$, the value for unconditional.
  - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to $0b1110$, or to the value of any condition that applied to the instruction.

Bits [19:1]
Reserved, RES0.

TI, bit [0]
Trapped instruction. Possible values of this bit are:

0  WFI trapped.
1  WFE trapped.

The following sections describe configuration settings for generating this exception:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1560.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1578.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1586.

ISS encoding for an exception from an MCR or MRC access

This encoding is used by:

- Exceptions from MCR/MRC to CP15 from AArch32 as a result of configurable traps, enables, or disables that do not use code $0b000000$.
- Exceptions from MCR/MRC to CP14 from AArch32 as a result of configurable traps, enables, or disables that do not use code $0b000000$.
- Exceptions from MRC (or VMRS) to CP10 for MVFR0, MVFR1, MVFR2, or FPSID as a result of ID Group traps from AArch32 unless reported using code $0b000111$.

The ISS encoding for these exceptions is:
CV, bit [24]

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or
  set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from
AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1 and:
  — If the instruction is conditional, COND is set to the condition code field value from the
    instruction.
  — If the instruction is unconditional, COND is set to 0b1110.
• A conditional A32 instruction that is known to pass its condition code check can be presented
  either:
  — With COND set to 0b1110, the value for unconditional.
  — With the COND value held in the instruction.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  — CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the
    SPSR.IT field to determine the condition, if any, of the T32 instruction.
  — CV is set to 1 and COND is set to the condition code for the condition that applied to
    the instruction.
• For an implementation that, for both A32 and T32 instructions, takes an exception on a
  trapped conditional instruction only if the instruction passes its condition code check, these
  definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND
  field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

CRn, bits [13:10]

The CRn value from the issued instruction.
For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

### Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

### CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

### Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0: Write to coprocessor. MCR instruction.
- 1: Read from coprocessor. MRC or VMRS instruction.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- **Traps to EL1 of EL0 accesses to the Generic Timer registers** on page D1-1565.
- **Traps to EL1 of EL0 accesses to Performance Monitors registers** on page D1-1565.
- **Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers** on page D1-1568.
- **Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions** on page D1-1570.
- **Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions** on page D1-1570.
- **Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register** on page D1-1572.
- **Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations** on page D1-1572.
- **Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers** on page D1-1574.
- **Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1578.**
- **General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only** on page D1-1580.
- **Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers** on page D1-1583.
- **Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers** on page D1-1584.
- **Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1586.**
- **Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1588.**
- **Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers** on page D1-1592.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- **Traps to EL1 of EL0 and EL1 System register accesses to the trace registers** on page D1-1563.
- **Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers** on page D1-1564.
- **Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers** on page D1-1574, for trapped accesses to the JIDR.
- **Traps to EL2 of Non-secure system register accesses to the trace registers on page D1-1579.**
- **Trapping System register accesses to Debug ROM registers to EL2 on page D1-1581.**
- **Trapping System register accesses to powerdown debug registers to EL2 on page D1-1582.**
• Trapping general System register accesses to debug registers to EL2 on page D1-1582.
• Traps to EL3 of all System register accesses to the trace registers on page D1-1589.
• Trapping System register accesses to powerdown debug registers to EL3 on page D1-1591.
• Trapping general System register accesses to debug registers to EL3 on page D1-1591.

Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1574 describes configuration settings for generating exceptions that are reported using EC value 0b0001000.

**ISS encoding for an exception from an MCRR or MRRC access**

This encoding is used by:

• Exceptions from MCRR/MRRC to CP15 from AArch32 as a result of configurable traps, enables, or disables that do not use code 0b000000.

• Exceptions from MCRR/MRRC to CP14 from AArch32 as a result of configurable traps, enables, or disables.

The ISS encoding for these exceptions is:

```
24 23 20 19 16 15 14 10 9 5 4 1 0
| CV | COND | Opc1 | Rt2 | Rt | CRm |
```

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.
For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1.
• When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:

• When an A32 instruction is trapped, CV is set to 1 and:
  — If the instruction is conditional, COND is set to the condition code field value from the instruction.
  — If the instruction is unconditional, COND is set to 0b1110.
• A conditional A32 instruction that is known to pass its condition code check can be presented either:
  — With COND set to 0b1110, the value for unconditional.
  — With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to \(0b1110\), or to the value of any condition that applied to the instruction.

**Opc1, bits [19:16]**

The Opc1 value from the issued instruction.

**Bit [15]**

Reserved, RES0.

**Rt2, bits [14:10]**

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0: Write to coprocessor. MCRR instruction.
- 1: Read from coprocessor. MRRC instruction.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b000100\):

- Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1565.
- Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1565.
- Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1568.
- General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1580.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1583.
- Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1584.
- Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1592.

The following sections describe configuration settings for generating exceptions that are reported using EC value \(0b001100\):

- Traps to EL1 of EL0 accesses to the trace registers on page D1-1563.
- Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1564.
- Traps to EL2 of Non-secure system register accesses to the trace registers on page D1-1579.
- Trapping System register accesses to Debug ROM registers to EL2 on page D1-1581.
- Traps to EL3 of all System register accesses to the trace registers on page D1-1589.
• Trapping System register accesses to powerdown debug registers to EL2 on page D1-1582.

**ISS encoding for an exception from an LDC or STC access to CP14**

This encoding is used by Exceptions from LDC/STC to CP14 from AArch32 as a result of configurable traps, enables, or disables.

The only architected uses of these instructions to access CP14 are:

- An STC to write to DBGDTRX_EL0 or DBGDTRRXint.
- An LDC to read from DBGDTRTX_EL0 or DBGDTRTXint.

The ISS encoding for these exceptions is:

```
<table>
<thead>
<tr>
<th></th>
<th>Cond</th>
<th>imm8</th>
<th>Rn</th>
<th>AM</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>CV</td>
<td>23-19</td>
<td>12-9</td>
<td>5-3</td>
</tr>
</tbody>
</table>
```

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The COND field is not valid.</td>
</tr>
<tr>
<td>1</td>
<td>The COND field is valid.</td>
</tr>
</tbody>
</table>

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to \(0b1110\).

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to \(0b1110\).
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to \(0b1110\), the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to \( \text{0b1110} \), or to the value of any condition that applied to the instruction.

**imm8, bits [19:12]**

The immediate value from the issued instruction.

**Bits [11:10]**

Reserved, RES0.

**Rn, bits [9:5]**

The Rn value from the issued instruction. Valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction.

When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

**Offset, bit [4]**

Indicates whether the offset is added or subtracted:

0 Subtract offset.

1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

**AM, bits [3:1]**

Addressing mode. The permitted values of this field are:

- 000 Immediate unindexed.
- 001 Immediate post-indexed.
- 010 Immediate offset.
- 011 Immediate pre-indexed.
- 100 Literal unindexed. A32 instruction set only.
  For a trapped LDC T32 instruction or STC T32 instruction, this encoding is reserved.
- 110 Literal offset.
  For the STC instruction, valid only in the A32 instruction set.
  For a trapped STC T32 instruction, this encoding is reserved.

The values \( \text{0b101} \) and \( \text{0b111} \) are reserved.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

0 Write to memory. STC instruction.

1 Read from memory. LDC instruction.

The following sections describe the configuration settings for the traps that are reported using EC value \( \text{0b000110} \):

- **Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1564.**
- **Trapping general System register accesses to debug registers to EL2 on page D1-1582.**
- **Trapping general System register accesses to debug registers to EL3 on page D1-1591.**
**ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP**

This encoding is used by Exceptions from an access to an Advanced SIMD or floating-point register as a result of CPACR_EL1.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP. Excludes exceptions resulting from an HCR_EL2.TGE value of 1 that are reported with EC value 0b000000 as described in EC encodings when routing exceptions to EL2 on page D1-1531.

The ISS encoding for these exceptions is:

```
+--------+-------+--------+--------+
| CV     | COND  | RES0   |
+--------+-------+--------+
| 24     | 23    | 20     |
```  

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.
Bits [19:0]

Reserved, RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- **Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality on page D1-1563.**
- **General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1579.**
- **Traps to EL3 of all System register accesses to the trace registers on page D1-1589.**

**ISS encoding for an exception from an Illegal execution state, or a PC or SP alignment fault**

This encoding is used by:

- Exceptions that occur because the value of PSTATE.IL is 1.
- PC alignment fault.
- SP alignment fault.

The ISS encoding for these exceptions is:

![ ISS encoding for an exception from an Illegal execution state, or a PC or SP alignment fault ]

Bits [24:0]

Reserved, RES0.

There are no configuration settings for generating Illegal execution state exceptions and PC alignment fault exceptions. *Stack pointer alignment checking on page D1-1510* describes the configuration settings for generating SP alignment fault exceptions.

**ISS encoding for an exception from HVC or SVC instruction execution**

This encoding is used by:

- SVC executed in AArch32 state. This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.
- HVC that is not disabled executed in AArch32 state.
- SVC executed in AArch64 state.
- HVC that is not disabled executed in AArch64 state.

The ISS encoding for these exceptions is:

![ ISS encoding for an exception from HVC or SVC instruction execution ]

Bits [24:16]

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.
For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction. For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see SVC, and HVC.

For A64 instructions, see SVC and HVC.

**ISS encoding for an exception from SMC instruction execution in AArch32 state**

This encoding is used by SMC that is not disabled executed in AArch32 state.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

The ISS encoding for these exceptions is:

```
+----------------+------------------+
| 24 23 20 19 18 | 0                |
|                |                  |
| COND           | RES0             |
|                |                  |
| CV             | CCKNOWNPASS      |
```

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from Non-secure EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1. For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

**COND, bits [23:20]**

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.
For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to $0b1110$.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to $0b1110$, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to $0b1110$, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

**CCKNOWNPASS, bit [19]**

Indicates whether the instruction might have failed its condition code check for execution.

- 0 The instruction was unconditional, or was conditional and passed its condition code check.
- 1 The instruction was conditional, and might have failed its condition code check.

**Bits [18:0]**

Reserved, RES0.

*Traps to EL2 of Non-secure EL1 execution of SMC instructions* on page D1-1573 describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and *System calls* on page D1-1593 describes the case where these exceptions are trapped to EL3.

**ISS encoding for an exception from SMC instruction execution in AArch64 state**

This encoding is used by SMC that is not disabled executed in AArch64 state.

This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

The ISS encoding for these exceptions is:

```
<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>imm16</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the issued SMC instruction.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1 modes.
• When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1573 describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and System calls on page D1-1593 describes the case where these exceptions are trapped to EL3.

### ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

This encoding is used by Exceptions from MSR, MRS, or System AArch64 instructions as a result of configurable traps, enables, or disables, except those reported using EC values 000000, 000001, or 000111.

This include all instructions that cause exceptions that are part of the encoding space defined in System instruction class encoding overview on page C5-245, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

The ISS encoding for these exceptions is:

| 24 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | Op0 | Op2 | Op1 | CRn | Rt | CRm |

**Bits [24:22]**

Reserved, RES0.

**Op0, bits [21:20]**

The Op0 value from the issued instruction.

**Op2, bits [19:17]**

The Op2 value from the issued instruction.

**Op1, bits [16:14]**

The Op1 value from the issued instruction.

**CRn, bits [13:10]**

The CRn value from the issued instruction.

**Rt, bits [9:5]**

The Rt value from the issued instruction, the general-purpose register used for the transfer.

**CRm, bits [4:1]**

The CRm value from the issued instruction.

**Direction, bit [0]**

Indicates the direction of the trapped instruction. The possible values of this bit are:

0  Write access, including MSR instructions.
1  Read access, including MRS instructions.

For exceptions caused by System instructions, see System on page C4-186 for the encoding values returned by an instruction.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

• In EL1 configurable controls on page D1-1559.
  — Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-1560.
— Traps to EL1 of EL0 accesses to the CTR_EL0 on page D1-1560.
— Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-1561.
— Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1561.
— Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1563.
— Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1564.
— Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1565.
— Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1565.

• In EL2 configurable controls on page D1-1567.
  — Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1568.
  — Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions on page D1-1569.
  — Traps to EL2 of Non-secure EL0 execution of TLB maintenance instructions on page D1-1570.
  — Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1570.
  — Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1572.
  — Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1572.
  — Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1574.
  — Trapping to EL2 of Non-secure EL0 accesses to the CPACR_EL1 or CPACR on page D1-1578.
  — Traps to EL2 of Non-secure system register accesses to the trace registers on page D1-1579.
  — Trapping System register accesses to Debug ROM registers to EL2 on page D1-1581.
  — Trapping System register accesses to powerdown debug registers to EL2 on page D1-1582.
  — Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1583.
  — Trapping general System register accesses to debug registers to EL2 on page D1-1582.
  — Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1584.

• In EL3 configurable controls on page D1-1585.
  — Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers on page D1-1587.
  — Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1588.
  — Traps to EL3 of all System register accesses to the trace registers on page D1-1589.
  — Trapping System register accesses to powerdown debug registers to EL3 on page D1-1591.
  — Trapping general System register accesses to debug registers to EL3 on page D1-1591.
  — Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1592.

**ISS encoding for a IMPLEMENTATION DEFINED exception to EL3**

This encoding is used by Reserved for IMPLEMENTATION DEFINED exceptions to EL3.

The ISS encoding for these exceptions is:
IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

**ISS encoding for an exception from an Instruction abort**

This encoding is used by:

- Instruction Abort that caused entry from a lower Exception level, where that Exception level could be using AArch64 or using AArch32. Used for MMU faults generated by instruction accesses and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

- Instruction Abort from the current Exception level, where the current Exception level must be using AArch64. Used for MMU faults generated by instruction accesses and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

The ISS encoding for these exceptions is:

```plaintext

```

**Bits [24:11]**

Reserved, RES0.

**FnV, bit [10]**

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0: FAR is valid.
- 1: FAR is not valid, and holds an **UNKNOWN** value.

This field is only valid if the IFSC code is 010000. It is RES0 for all other aborts.

**EA, bit [9]**

External abort type. This bit can provide an **IMPLEMENTATION DEFINED** classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

**Bit [8]**

Reserved, RES0.
S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

0  Fault not on a stage 2 translation for a stage 1 translation table walk.
1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a fault other than a stage 2 fault, this bit is RES0.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

000000  Address size fault, zeroth level of translation or translation table base register
000001  Address size fault, first level
000010  Address size fault, second level
000011  Address size fault, third level
000100  Translation fault, zeroth level
000101  Translation fault, first level
000110  Translation fault, second level
000111  Translation fault, third level
001001  Access flag fault, first level
001010  Access flag fault, second level
001011  Access flag fault, third level
001101  Permission fault, first level
001110  Permission fault, second level
001111  Permission fault, third level
010000  Synchronous external abort, not on translation table walk
010100  Synchronous parity or ECC error on memory access, not on translation table walk
010101  Synchronous external abort on translation table walk, zeroth level
010110  Synchronous external abort on translation table walk, first level
010111  Synchronous external abort on translation table walk, second level
011100  Synchronous external abort on translation table walk, third level
011101  Synchronous parity or ECC error on memory access on translation table walk, zeroth level
011110  Synchronous parity or ECC error on memory access on translation table walk, first level
011111  Synchronous parity or ECC error on memory access on translation table walk, second level
011111  Synchronous parity or ECC error on memory access on translation table walk, third level
100001  Alignment fault
110000  TLB conflict abort

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.

- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

**Note**

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at the zeroth level.

**ISS encoding for an exception from a Data abort**

This encoding is used by:

- Data Abort that caused entry from a lower Exception level, where that Exception level could be using AArch64 or using AArch32.
  
  Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

- Data Abort that caused entry from a current Exception level, where the current Exception level must be using AArch64.
  
  Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

The ISS encoding for these exceptions is:

```
  24 23 22 21 20 16 15 14 13 11 10  9  8  7  6  5  0
  +---------------+---------------+---------------+---------------+
  |   SAS         |   SRT         |   RES0        |   DFSC        |
  +---------------+---------------+---------------+---------------+
  | ISV | SSE | SF | AR | WnR | S1PTW | CM | EA | FnV|
```

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

0  No valid instruction syndrome. ISS[23:14] are RES0.
1  ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111), including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback.
- AArch32 instructions where the instruction:
  
  — Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STRT, STR, STRT, STR, STRT, STRH, STRBT, STRB, STLB, or STRBT instruction.
  
  — Is not performing register writeback.
Is not using R15 as a source or destination register.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

For ISS reporting, a stage 2 abort on a stage 1 translation table does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

The value of ISV on a synchronous external abort on a stage 2 translation table walk is IMPLEMENTATION DEFINED.

**SAS, bits [23:22]**
Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Byte</td>
</tr>
<tr>
<td>01</td>
<td>Halfword</td>
</tr>
<tr>
<td>10</td>
<td>Word</td>
</tr>
<tr>
<td>11</td>
<td>Doubleword</td>
</tr>
</tbody>
</table>

This field is RES0 when the value of ISV is 0.

**SSE, bit [21]**
Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sign-extension not required.</td>
</tr>
<tr>
<td>1</td>
<td>Data item must be sign-extended.</td>
</tr>
</tbody>
</table>

For all other operations this bit is 0.

This field is RES0 when the value of ISV is 0.

**SRT, bits [20:16]**
Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction, as viewed in AArch64 state.

This field is RES0 when the value of ISV is 0.

**SF, bit [15]**
Width of the register accessed by the instruction is Sixty-Four. When ISV is 1, the possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Instruction loads/stores a 32-bit wide register.</td>
</tr>
<tr>
<td>1</td>
<td>Instruction loads/stores a 64-bit wide register.</td>
</tr>
</tbody>
</table>

**Note**
This field specifies the register width identified by the instruction, not the Execution state.

This field is RES0 when the value of ISV is 0.

**AR, bit [14]**
Acquire/Release. When ISV is 1, the possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Instruction did not have acquire/release semantics.</td>
</tr>
<tr>
<td>1</td>
<td>Instruction did have acquire/release semantics.</td>
</tr>
</tbody>
</table>

This field is RES0 when the value of ISV is 0.

**Bits [13:11]**
Reserved, RES0.
FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0  FAR is valid.
1  FAR is not valid, and holds an UNKNOWN value.

This field is only valid if the DFSC code is 010000. It is RES0 for all other aborts.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Indicates the data fault came from a Cache Maintenance Instruction, other than DC ZVA instruction, or from a synchronous fault on an address translation instruction that translates a VA to a PA.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

0  Fault not on a stage 2 translation for a stage 1 translation table walk.
1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a fault other than a stage 2 fault, this bit is RES0.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction. The possible values of this bit are:

0  Abort caused by a read instruction.
1  Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For an asynchronous Data Abort exception this bit is UNKNOWN.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

000000  Address size fault, zeroth level of translation or translation table base register
000001  Address size fault, first level
000010  Address size fault, second level
000011  Address size fault, third level
000100  Translation fault, zeroth level
000101  Translation fault, first level
000110  Translation fault, second level
000111  Translation fault, third level
001001  Access flag fault, first level
001010  Access flag fault, second level
001011  Access flag fault, third level
001101  Permission fault, first level
001110  Permission fault, second level
001111  Permission fault, third level
010000  Synchronous external abort, not on translation table walk
Synchronous parity or ECC error on memory access, not on translation table walk 011000
Synchronous external abort on translation table walk, zeroth level 010100
Synchronous external abort on translation table walk, first level 010101
Synchronous external abort on translation table walk, second level 010110
Synchronous external abort on translation table walk, third level 010111
Synchronous parity or ECC error on memory access on translation table walk, zeroth level 011100
Synchronous parity or ECC error on memory access on translation table walk, first level 011101
Synchronous parity or ECC error on memory access on translation table walk, second level 011110
Synchronous parity or ECC error on memory access on translation table walk, third level 011111
Alignment fault 100001
TLB conflict abort 110000
IMPLEMENTATION DEFINED fault (Lockdown fault) 110100
IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault) 110101
Section Domain Fault, used only for faults reported in the PAR_EL1 111101
Page Domain Fault, used only for faults reported in the PAR_EL1 111110

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Note
Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at the zeroth level.

ISS encoding for an exception from a trapped Floating-point exception

This encoding is used by:

- Exceptions as a result of Floating-point exception from AArch32. Whether this Exception class is supported is IMPLEMENTATION DEFINED.
- Exceptions as a result of Floating-point exception from AArch64. Whether this Exception class is supported is IMPLEMENTATION DEFINED.

The ISS encoding for these exceptions is:
Bit [24]
- Reserved, RES0.

TFV, bit [23]
- Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about a trapped fault. The possible values of this bit are:
  - 0: The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about a trapped fault and are UNKNOWN.
  - 1: The IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about one or more trapped faults. All Floating-point exceptions indicated by these bits have occurred since the bits were last cleared to 0.

Bits [22:11]
- Reserved, RES0.

VECITR, bits [10:8]
- For a trapped Floating-point exception from an instruction executed in AArch32 state this field is RES0.
- For a trapped Floating-point exception from a scalar floating-point instruction executed in AArch64 state this field is RES0.
- For a trapped Floating-point exception from a vector floating-point instruction executed in AArch64 state this field holds the number of the element that is being reported in ESR_ELx. That is, it holds the number of the element that generated the reported Floating-point exception.
- For an instruction that combines two adjacent elements to creating a single element, VECITR reports the lower-numbered input element. This can occur with the pairwise instructions, for example the FADDP instruction.
- For an instruction that produces a single value from all the elements in the input vector, the only possible exceptions result from the input operands, and are an Invalid Operation exception on a Signaling NaN, or an Input Denormal exception. In these cases, VECITR reports the element number that is being reported in the ESR. This can occur with the across-lanes instructions, for example FMAXV.
- VECITR holds an element number as an unsigned binary number.

IDF, bit [7]
- Input Denormal Floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:
  - 0: Input denormal floating-point exception has not occurred.
  - 1: Input denormal floating-point exception has occurred since the bit was last set to 0.

Bits [6:5]
- Reserved, RES0.
IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is **UNKNOWN**. Otherwise, the possible values of this bit are:

0  Inexact floating-point exception has not occurred.
1  Inexact floating-point exception has occurred since the bit was last set to 0.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is **UNKNOWN**. Otherwise, the possible values of this bit are:

0  Underflow floating-point exception has not occurred.
1  Underflow floating-point exception has occurred since the bit was last set to 0.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is **UNKNOWN**. Otherwise, the possible values of this bit are:

0  Overflow floating-point exception has not occurred.
1  Overflow floating-point exception has occurred since the bit was last set to 0.

DZF, bit [1]

Divide-by-zero floating-point exception trapped bit. If the TFV field is 0, this bit is **UNKNOWN**. Otherwise, the possible values of this bit are:

0  Divide-by-zero floating-point exception has not occurred.
1  Divide-by-zero floating-point exception has occurred since the bit was last set to 0.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is **UNKNOWN**. Otherwise, the possible values of this bit are:

0  Invalid Operation floating-point exception has not occurred.
1  Invalid Operation floating-point exception has occurred since the bit was last set to 0.

In an implementation where the SIMD and floating-point implementation supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the `FPCR.{IDE, IXE, UFE, OFE, DZE, IOE}` bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the `FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE}` bits enable each of the floating-point exception traps.

**ISS encoding for an SError interrupt**

This encoding is used by SError Interrupt.

The ISS encoding for these exceptions is:
ISV, bit [24]

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

0  No valid instruction syndrome. ISS[23:0] are RES0.
1  ISS[23:0] hold a valid instruction syndrome.

IS, bits [23:0]

IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt. Only valid if bit[24] of this register is 1. If bit[24] is 0, this field is RES0.

**ISS encoding for an exception from a Breakpoint or Vector Catch debug event**

This encoding is used by:

- Breakpoint debug event that caused entry from a lower Exception level.
- Breakpoint debug event from the current Exception level.
- AArch32 state Vector catch debug event.

The only case where an exception from a Vector catch debug event is taken to an Exception level that is using AArch64 is when the Vector catch is routed to EL2 and EL2 is using AArch64.

The ISS encoding for these exceptions is:

```
   24 6 5 0
   RES0 IFSC
```

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug event.

For more information about generating these exceptions:

- For exceptions from AArch64, see [Breakpoint exceptions](#) on page D2-1638.
- For exceptions from AArch32, see [Breakpoint exceptions](#) on page G2-3970 and [Vector Catch exceptions](#) on page G2-4009.

**ISS encoding for an exception from a Software Step debug event**

This encoding is used by:

- Software step debug event that caused entry from a lower Exception level.
- Software step debug event from the current Exception level.

The ISS encoding for these exceptions is:
ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:
0   EX bit is RES0.
1   EX bit is valid.

See the EX bit description for more information.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.
0   An instruction other than a Load-Exclusive instruction was stepped.
1   A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

IFSC, bits [5:0]

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug event.

For more information about generating these exceptions, see Software Step exceptions on page D2-1671.

**ISS encoding for an exception from a Watchpoint debug event**

This encoding is used by:

- Watchpoint debug event that caused entry from a lower Exception level.
- Watchpoint debug event from the current Exception level.

The ISS encoding for these exceptions is:

```
<table>
<thead>
<tr>
<th>24</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [24:9]**

Reserved, RES0.

CM, bit [8]

Indicates the data fault came from a Cache Maintenance Instruction, other than DC ZVA instruction, or from a synchronous fault on an address translation instruction that translates a VA to a PA.
Bit [7]
Reserved, RES0.

WnR, bit [6]
Write not Read. Indicates whether the abort was caused by a write instruction or a read instruction.
The possible values of this bit are:
0 Abort caused by a read instruction.
1 Abort caused by a write instruction.
For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

DFSC, bits [5:0]
Data Fault Status Code. This field is set to 0b100010, to indicate a Debug event.
For more information about generating these exceptions, see Watchpoint exceptions on page D2-1656.

**ISS encoding for an exception from execution of a Software Breakpoint instruction**

This encoding is used by:
- BKPT instruction executed in AArch32 state.
- BRK instruction executed in AArch64 state.
  This is reported in ESR_EL3 only if a BRK instruction is executed at EL3.

The ISS encoding for these exceptions is:

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Comment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [24:16]
Reserved, RES0.

Comment, bits [15:0]
Set to the instruction comment field value, zero extended as necessary. For the AArch32 BKPT instructions, the comment field is described as the immediate field.

For more information about generating these exceptions, see Software Breakpoint Instruction exceptions on page D2-1636.
D7.2.28 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

**Purpose**

Holds the faulting Virtual Address for all synchronous instruction or data aborts, or exceptions from a misaligned PC or a Watchpoint debug event, taken to EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Execution at EL0 makes FAR_EL1 become UNKNOWN.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization](page D1-1546). Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register FAR_EL1[31:0] is architecturally mapped to AArch32 System register DFAR (NS).

AArch64 System register FAR_EL1[63:32] is architecturally mapped to AArch32 System register IFAR (NS).

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

FAR_EL1 is a 64-bit register.

**Field descriptions**

The FAR_EL1 bit assignments are:

Faulting Virtual Address for synchronous exceptions taken to EL1

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are instruction aborts (EC 0x20 or 0x21), data aborts (EC 0x24 or 0x25), a misaligned PC exception (EC 0x22), or a Watchpoint exception (EC 0x34 or 0x35). ESR_EL1.EC holds the EC value for the exception.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if ESR_EL1.FnV is 0, and the FAR_EL1 is UNKNOWN if ESR_EL1 is 1.

For all other exceptions taken to EL1, the FAR_EL1 is UNKNOWN.

If a memory fault that sets FAR_EL1 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.
If the exception that updates FAR_EL1 is taken from an Exception level that is using AArch32, the
top 32 bits are all zero, unless the faulting address is generated by a load or store instruction that
sequentially increments from address 0xFFFFFFFF. This is an UNPREDICTABLE condition, and in this
case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by
the data access that caused the exception, then this field includes the tag. For more information
about address tagging, see Address tagging in AArch64 state on page D4-1726.

--- Note ---

The address held in this field is an address accessed by the instruction fetch or data access that
causethedexceptionthatgaverisetothediructionordataabort.Itisthelowestaddress that gave
risetothefault.Wheredifferentfaultsfromdifferentaddressesarisefromthesameinstruction,such
as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the
architecture does not prioritize between those different faults.

FAR_EL1 is made UNKNOWN on an exception return from EL1.

Accessing the FAR_EL1:

To access the FAR_EL1:

MRS <Xt>, FAR_EL1 ; Read FAR_EL1 into Xt
MSR FAR_EL1, <Xt> ; Write Xt to FAR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0110</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.29 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

**Purpose**

Holds the faulting Virtual Address for all synchronous instruction or data aborts, or exceptions from a misaligned PC or a Watchpoint debug event, taken to EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Execution at EL1 or EL0 makes FAR_EL2 become UNKNOWN.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register FAR_EL2[31:0] is architecturally mapped to AArch32 System register HDFAR.
AArch64 System register FAR_EL2[63:32] is architecturally mapped to AArch32 System register HIFAR.
AArch64 System register FAR_EL2[31:0] is architecturally mapped to AArch32 System register DFAR (S) when EL2 is implemented.
AArch64 System register FAR_EL2[63:32] is architecturally mapped to AArch32 System register IFAR (S) when EL2 is implemented.
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

FAR_EL2 is a 64-bit register.

**Field descriptions**

The FAR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Faulting Virtual Address for synchronous exceptions taken to EL2</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:0]**

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are instruction aborts (EC 0x20 or 0x21), data aborts (EC 0x24 or 0x25), a misaligned PC exception (EC 0x22), or a Watchpoint exception (EC 0x34 or 0x35). ESR_EL2.EC holds the EC value for the exception.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if ESR_EL2.FnV is 0, and the FAR_EL2 is UNKNOWN if ESR_EL2 is 1.

For all other exceptions taken to EL2, the FAR_EL2 is UNKNOWN.

If a memory fault that sets FAR_EL2 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.
If the exception that updates FAR_EL2 is taken from an Exception level that is using AArch32, the top 32-bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address \texttt{0xFFFFFFFF}. This is an \textit{UNPREDICTABLE} condition, and in this case the upper 32-bits are set to \texttt{0x00000001}.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see \textit{Address tagging in AArch64 state} on page D4-1726.

\textbf{Note}

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL2 is made \textit{UNKNOWN} on an exception return from EL2.

\textbf{Accessing the FAR_EL2:}

To access the FAR_EL2:

\begin{verbatim}
MRS <Xt>, FAR_EL2 ; Read FAR_EL2 into Xt
MSR FAR_EL2, <Xt> ; Write Xt to FAR_EL2
\end{verbatim}

Register access is encoded as follows:

\begin{verbatim}
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0110</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
\end{verbatim}
D7.2.30 FAR_EL3, Fault Address Register (EL3)

The FAR_EL3 characteristics are:

**Purpose**

Holds the faulting Virtual Address for all synchronous instruction or data aborts, or exceptions from a misaligned PC, taken to EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Execution at EL2, EL1 or EL0 makes FAR_EL3 become UNKNOWN.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

FAR_EL3 is a 64-bit register.

**Field descriptions**

The FAR_EL3 bit assignments are:

```
63 0
```

Faulting Virtual Address for synchronous exceptions taken to EL3

**Bits [63:0]**

Faulting Virtual Address for synchronous exceptions taken to EL3. Exceptions that set the FAR_EL3 are instruction aborts (EC 0x20 or 0x21), data aborts (EC 0x24 or 0x25), a misaligned PC exception (EC 0x22). ESR_EL3.EC holds the EC value for the exception.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if ESR_EL3.FnV is 0, and the FAR_EL3 is UNKNOWN if ESR_EL3 is 1.

For all other exceptions taken to EL3, the FAR_EL3 is UNKNOWN.

If a memory fault that sets FAR_EL3 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL3 is taken from an EL using AArch32, the top 32-bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xffffffff. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see Address tagging in AArch64 state on page D4-1726.
Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL3 is made UNKNOWN on an exception return from EL3.

Accessing the FAR_EL3:

To access the FAR_EL3:

MRS <Xt>, FAR_EL3 ; Read FAR_EL3 into Xt
MSR FAR_EL3, <Xt> ; Write Xt to FAR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0110</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.31 FPEXC32_EL2, Floating-point Exception Control register

The FPEXC32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register FPEXC from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If CPTR_EL2.TFP==1, Non-secure EL2 accesses to this register are trapped to EL2.
- If CPTR_EL3.TFP==1, EL2 and EL3 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register FPEXC32_EL2 is architecturally mapped to AArch32 System register FPEXC.

If EL1 cannot use AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

FPEXC32_EL2 is a 32-bit register.

**Field descriptions**

The FPEXC32_EL2 bit assignments are:

```
  31 30 29 28 27 26 25 21 20 11 10  8  7  6  5  4  3  2  1  0
   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
   EX EN DEX FP2V TFV   VV RES0 IMPLEMENTATION DEFINED VECITR   IOF DZF OFF UFF IXF IMP DEF IDF
```

**EX, bit [31]**

Exception bit. A status bit that specifies how much information must be saved to record the state of the Advanced SIMD and VFP implementation:

- 0: The only significant state is the contents of the registers D0 - D31, FPSCR, and FPEXC. A context switch can be performed by saving and restoring the values of these registers.
There is additional state that must be handled by any context switch system. In ARMv8, this bit must be RES0.

**EN, bit [30]**

Enables PL2, PL1, and PL0 accesses to the SIMD and floating-point registers, except for the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

0  PL2, PL1, and PL0 accesses to the FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED.

1  PL2, PL1, and PL0 accesses are enabled.

If any of CPACR.{cp11, cp10}, FPEXC.EN, or for Advanced SIMD instructions, CPACR.ASEDIS, disable a floating-point or an Advanced SIMD instruction, the instruction is UNDEFINED.

This bit is made obsolete by the features in the CPACR when executing in AArch64.

When executing in EL0 using AArch32 with EL1 using AArch64, the behavior is as if the FPEXC.EN bit is set.

**DEX, bit [29]**

Defined synchronous instruction exception bit.

When a floating-point synchronous exception has occurred, if the exception was caused by an allocated floating-point instruction that is not implemented in hardware then it is IMPLEMENTATION DEFINED whether DEX is set to 0 or 1.

Otherwise, the meaning of this bit is:

0  A synchronous exception occurred when processing an unallocated floating-point or Advanced SIMD instruction.

1  A synchronous exception occurred on an allocated floating-point instruction that encountered an exceptional condition.

The exception-handling routine must clear DEX to 0.

In an implementation that does not require synchronous exception handling this bit is RES0.

**FP2V, bit [28]**

FPINST2 instruction valid bit. In ARMv8, this field is always RES0.

**VV, bit [27]**

VECITR valid bit. In ARMv8, this field is always RES0.

**TFV, bit [26]**

Trapped Fault Valid bit. Indicates whether FPEXC bits[7, 4:0] indicate trapped exceptions, or have an IMPLEMENTATION DEFINED meaning:

0  FPEXC bits[7, 4:0] have an IMPLEMENTATION DEFINED meaning

1  FPEXC bits[7, 4:0] indicate the presence of trapped exceptions that have occurred at the time of the exception. All trapped exceptions that occurred at the time of the exception have their bits set.

This bit has a fixed value and ignores writes.

**Bits [25:21]**

Reserved, RES0.

**IMPLEMENTATION DEFINED, bits [20:11]**

IMPLEMENTATION DEFINED.
VECITR, bits [10:8]

Vector iteration count. In ARMv8, this field is always RES1.

IDF, bit [7]

Input Denormal trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Input Denormal trapped exception bit, and indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0 Input denormal exception has not occurred.
1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.
In both cases this bit must be cleared to 0 by the exception-handling routine.

IMP DEF, bits [6:5]

IMPLEMENTATION DEFINED.

IXF, bit [4]

Inexact trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Inexact trapped exception bit, and indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

In this case, the meaning of this bit is:

0 Inexact exception has not occurred.
1 Inexact exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

UFF, bit [3]

Underflow trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Underflow trapped exception bit, and indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0 Underflow exception has not occurred.
1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.
In both cases this bit must be cleared to 0 by the exception-handling routine.

OFF, bit [2]

Overflow trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Overflow trapped exception bit, and indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0 Overflow exception has not occurred.
1 Overflow exception has occurred.
In both cases this bit must be cleared to 0 by the exception-handling routine.

**DZF, bit [1]**

Divide-by-zero trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Divide-by-zero trapped exception bit, and indicates whether a Divide-by-zero exception occurred while FPSCR.DZE was 1:

0  Divide-by-zero exception has not occurred.
1  Divide-by-zero exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

**IOF, bit [0]**

Invalid Operation trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Invalid Operation trapped exception bit, and indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

0  Invalid Operation exception has not occurred.
1  Invalid Operation exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

**Accessing the FPEXC32_EL2:**

To access the FPEXC32_EL2:

```
MRS <Xt>, FPEXC32_EL2 ; Read FPEXC32_EL2 into Xt
MSR FPEXC32_EL2, <Xt> ; Write Xt to FPEXC32_EL2
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0101</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.32   HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

**Purpose**

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register HACR_EL2 is architecturally mapped to AArch32 System register HACR.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

HACR_EL2 is a 32-bit register.

**Field descriptions**

The HACR_EL2 bit assignments are:

![Field descriptions diagram]

**Accessing the HACR_EL2:**

To access the HACR_EL2:

MRS <Xt>, HACR_EL2 ; Read HACR_EL2 into Xt
MSR HACR_EL2, <Xt> ; Write Xt to HACR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.2.33 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

**Purpose**

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register HCR_EL2[31:0] is architecturally mapped to AArch32 System register HCR.

AArch64 System register HCR_EL2[63:32] is architecturally mapped to AArch32 System register HCR2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

HCR_EL2 is a 64-bit register.

**Field descriptions**

The HCR_EL2 bit assignments are:
Bits [63:39]
Reserved, RES0.

MIOCNCE, bit [38]
Mismatched Inner/Outer Cacheable Non-Coherency Enable.

0  Does not permit that if the Inner Cacheable attribute does not match the Outer Cacheable attribute for a memory location, then there can be a loss of coherency for the Non-secure EL1 translation regime in the presence of mismatched memory attributes.

1  Permits that if the Inner Cacheable attribute does not match the Outer Cacheable attribute for a memory location, then there can be a loss of coherency for the Non-secure EL1 translation regime in the presence of mismatched memory attributes.

Implementations are permitted to make this bit RAZ/WI.

Bits [37:34]
Reserved, RES0.

ID, bit [33]
Stage 2 Instruction cache disable. When HCR_EL2.VM==1, this forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the Non-secure EL1&0 translation regime.

0  No effect on the stage 2 of the Non-secure EL1&0 translation regime for instruction accesses.

1  Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the Non-secure EL1&0 translation regime.

This bit has no effect on the EL2 or EL3 translation regimes.

CD, bit [32]
Stage 2 Data cache disable. When HCR_EL2.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the Non-secure EL1&0 translation regime.

0  No effect on the stage 2 of the Non-secure EL1&0 translation regime for data accesses and translation table walks.

1  Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the Non-secure EL1&0 translation regime.

This bit has no effect on the EL2 or EL3 translation regimes.

RW, bit [31]
Execution state control for lower Exception levels:

0  Lower levels are all AArch32.

1  EL1 is AArch64. EL0 is determined by the Execution state described in the current process state when executing at EL0.

If all lower Exception levels cannot use AArch32 then this bit is RAO/WI.

When SCR_EL3.NS==0, this bit behaves as if it has the same value as the SCR_EL3.RW bit except for the value read back.

The RW bit is permitted to be cached in a TLB.

TRVM, bit [30]
Trap Reads of Virtual Memory controls. When set to 1, traps Non-secure EL1 reads of the virtual memory control registers to EL2, from both Execution states. The registers for which read accesses are trapped are as follows:

Non-secure EL1 using AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.
Non-secure EL1 using AArch32: SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, AFIFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

0  Non-secure EL1 read accesses to Virtual Memory controls are not trapped to EL2.
1  Non-secure EL1 read accesses to Virtual Memory controls are trapped to EL2.

**HCD, bit [29]**

Hypervisor Call instruction disable. Disables Non-secure state execution of HVC instructions, from both Execution states.

0  HVC instruction execution is enabled at EL2 and Non-secure EL1.
1  HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

--- Note ---

HVC instructions are always UNDEFINED at EL0.

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

**TDZ, bit [28]**

Trap DC ZVA instructions. Traps Non-secure EL0 and EL1 execution of DC ZVA instructions to EL2, from AArch64 state only.

0  Non-secure EL0 and EL1 execution of DC ZVA instructions is not trapped to EL2.
1  Any attempt to execute a DC ZVA instruction at Non-secure EL0 using AArch64 or Non-secure EL1 using AArch64 is trapped to EL2. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not supported.

**TGE, bit [27]**

Trap General Exceptions. If this bit is set to 1, and SCR_EL3.NS is set to 1, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The SCTLR_EL1.M bit is treated as being 0 regardless of its actual state (for EL1 using AArch32 or AArch64) other than for the purpose of reading the bit.
- The HCR_EL2.FMO, IMO and AMO bits are treated as being 1 regardless of their actual state other than for the purpose of reading the bits.
- All virtual interrupts are disabled.
- Any implementation defined mechanisms for signalling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.

Additionally, if HCR_EL2.TGE == 1, the MDCR_EL2.TDRA,TDOSA,TDA] bits are ignored and the PE behaves as if they are set to 1, other than for the value read back from MDCR_EL2.

**TVM, bit [26]**

Trap Virtual Memory controls. When set to 1, traps Non-secure EL1 writes to the virtual memory control registers to EL2, from both Execution states. The registers for which write accesses are trapped are as follows:

Non-secure EL1 using AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.

Non-secure EL1 using AArch32: SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

0  Non-secure EL1 write accesses to EL1 virtual memory control registers are not trapped to EL2.
1  Non-secure EL1 write accesses to EL1 virtual memory control registers are trapped to EL2.
TTLB, bit [25]

Trap TLB maintenance instructions. When set to 1, any attempt at Non-secure EL1 using AArch64 or Non-secure EL1 using AArch32 to execute a TLBI instruction is trapped to EL2. This applies to the following instructions:

Non-secure EL1 using AArch64: TLBI VMALLE1IS, TLBI VAEE1IS, TLBI ASIDE1IS, TLBI VAEE1IS, TLBI VALE1IS, TLBI VAEE1IS, TLBI VMALLE1, TLBI VAEE1, TLBI ASIDE1, TLBI VAEE1, TLBI VALE1, TLBI VAEE1.
Non-secure EL1 using AArch32: TLBIALISS, TLBMVAINS, TLBISIDIS, TLBIMVAIS, TLBIMVALIS, TLBIMVALLIS, ITLBIALL, ITLBIMVA, ITLBIASID, DTBLIALL, DTBLMVA, DTLBIASID, TBLIALL, TLBMVA, TBLIASID, TLBMVAA, TLBIMVAL, TLBIMVAIL.

0  Non-secure EL1 accesses to TLB maintenance instructions are not trapped to EL2.
1  Non-secure EL1 accesses to TLB maintenance instructions are trapped to EL2.

TPU, bit [24]

Trap cache maintenance instructions to Point of Unification. When set to 1, Non-secure EL0 and EL1 execution of cache maintenance instructions to the point of unification are trapped to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64 and Non-secure EL1 using AArch64: IC IVAU, IC IALLU, IC IALLUIS, DC CVAU.
Non-secure EL1 using AArch32: ICIMV AU, ICIALLU, ICIALLUIS, DCCMV AU.

Note

IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.
ICIMV AU, ICIALLU, ICIALLUIS, and DCCMV AU are always UNDEFINED at EL0 using AArch32.

0  EL0 and EL1 using AArch64: Non-secure EL0 and EL1 accesses to the IC IVAU, IC IALLU, IC IALLUIS, and DC CVAU instructions are not trapped to EL2.
EL0 and EL1 using AArch32: Non-secure EL0 and EL1 accesses to the ICIMV AU, ICIALLU, ICIALLUIS, and DCCMV AU instructions are not trapped to EL2.
1  EL0 and EL1 using AArch64: Non-secure EL0 and EL1 accesses to the IC IVAU, IC IALLU, IC IALLUIS, and DC CVAU instructions are trapped to EL2.
EL0 and EL1 using AArch32: Non-secure EL0 and EL1 accesses to the ICIMV AU, ICIALLU, ICIALLUIS, and DCCMV AU instructions are trapped to EL2.

TPC, bit [23]

Trap data or unified cache maintenance operations to Point of Coherency. When set to 1, Non-secure EL0 and EL1 execution of data or unified cache maintenance instructions by address to the point of coherency are trapped to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64 and Non-secure EL1 using AArch64: DC IVAC, DC CIVAC, DC CVAC.
Non-secure EL1 using AArch32: DCIMV AC, DCCIMV AC, DCCMV AC.

Note

DC IVAC is always UNDEFINED at EL0 using AArch64.
DCIMV AC, DCCIMV AC, and DCCMV AC are always UNDEFINED at EL0 using AArch32.

0  EL0 using AArch64: Non-secure EL0 accesses to the DC IVAC, DC CIVAC, and DC CVAC instructions are not trapped to EL2.
EL1 using AArch32: Non-secure EL1 accesses to the DCIMV AC, DCCIMV AC, and DCCMV AC instructions are not trapped to EL2.
1. EL0 using AArch64: Non-secure EL0 accesses to the DC IVAC, DC CIVAC, and DC CVAC instructions are trapped to EL2.
   EL1 using AArch32: Non-secure EL1 accesses to the DCIMVAC, DCCIMVAC, and DCCCMVMAC instructions are trapped to EL2.

TSW, bit [22]

Trap data or unified cache maintenance operations by Set/Way. When set to 1, Non-secure EL1 execution of data or unified cache maintenance instructions by set/way are trapped to EL2. This applies to the following instructions:

Non-secure EL1 using AArch64: DC ISW, DC CSW, DC CISW.
Non-secure EL1 using AArch32: DCISW, DCCSW, DCCISW.

--- Note ---

These instructions are always UNDEFINED at EL0.

0. EL1 using AArch64: Non-secure EL1 accesses to the DC ISW, DC CSW, and DC CISW instructions are not trapped to EL2.
   EL1 using AArch32: Non-secure EL1 accesses to the DCISW, DCCSW, and DCCISW instructions are not trapped to EL2.

1. EL1 using AArch64: Non-secure EL1 accesses to the DC ISW, DC CSW, and DC CISW instructions are trapped to EL2.
   EL1 using AArch32: Non-secure EL1 accesses to the DCISW, DCCSW, and DCCISW instructions are trapped to EL2.

TACR, bit [21]

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2, from both Execution states.

0. Non-secure EL1 accesses to the Auxiliary Control Registers are not trapped to EL2.
1. Non-secure EL1 using AArch64: Accesses to the ACTLR_EL1 are trapped to EL2.
   Non-secure EL1 using AArch32: Accesses to the ACTLR and, if implemented, the ACTLR2, are trapped to EL2.

TIDCP, bit [20]

Trap Implementation Dependent functionality. When set to 1, causes accesses to the following instruction set space executed from Non-secure EL1 to be trapped to EL2.

AArch64: All encoding space reserved for IMPLEMENTATION DEFINED system operations (S1 <op1> <cn> <cm> <op2>) and System registers (S3 <op1> <Cn> <Cm> <op2>).

AArch32: MCR and MRC instructions as follows:
- All CP15, CRn==9, opc1 == {0-7}, CRm == {c0-c2, c5-c8}, opc2 == {0-7}.
- All CP15, CRn==10, opc1 == {0-7}, CRm == {c0, c1, c4, c8}, opc2 == {0-7}.
- All CP15, CRn==11, opc1 == {0-7}, CRm == {c0-c8, c15}, opc2 == {0-7}.

When HCR_EL2.TIDCP is set to 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to EL2. If it is not, it is UNDEFINED, and the PE takes an Undefined Instruction exception to EL1.

0. Non-secure EL1 accesses to Implementation Dependent functionality are not trapped to EL2.
1. Non-secure EL1 accesses to Implementation Dependent functionality are trapped to EL2.

TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to EL2, from both Execution states.

0. Non-secure EL1 execution of SMC instructions is not trapped to EL2.
Any attempt to execute an SMC instruction at Non-secure EL1 using AArch64 or Non-secure EL1 using AArch32 is trapped to EL2, regardless of the value of SCR_EL3.SMD.

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

If EL3 is not implemented, this bit is RES0.

### TID3, bit [18]

Trap ID group 3. When set to 1, Non-secure EL1 reads of the following registers are trapped to EL2:

**AArch64**: ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MFMR2_EL1, ID_MFMR3_EL1, ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, ID_MVFR0_EL1, ID_MVFR1_EL1, ID_MVFR2_EL1, ID_MVFR3_EL1, ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64DFR2_EL1, ID_AA64DFR3_EL1, ID_AA64DFR4_EL1, ID_AA64DFR5_EL1, and, if it contains a non-zero value, ID_MMFR4_EL1.

**AArch32**: ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, ID_MVFR0, ID_MVFR1, ID_MVFR2, and, if it contains a non-zero value, ID_MMFR4.

AArch64 and AArch32: It is IMPLEMENTATION DEFINED whether this bit traps MRS or MRC accesses to encodings in the following range that are not already mentioned in this field description:

- AArch64: Op0 == 3, op1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}.
- AArch32: CP15, op1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}.

0: Non-secure EL1 read accesses to ID Group 3 are not trapped to EL2.

- PL1 using AArch32: Non-secure PL1 read accesses to the ID_MMFR4 register are not trapped to EL2 using AArch64.
- EL1 using AArch64: Non-secure EL1 read accesses to the ID_MMFR4_EL1 register are not trapped to EL2.

1: Non-secure EL1 read accesses to ID Group 3 are trapped to EL2.

- PL1 using AArch32: Non-secure PL1 read accesses to the ID_MMFR4 register are trapped to EL2 using AArch64, if this register contains a non-zero value.
- EL1 using AArch64: Non-secure EL1 read accesses to the ID_MMFR4_EL1 register are trapped to EL2, if this register contains a non-zero value.

### TID2, bit [17]

Trap ID group 2. When set to 1, the following register accesses are trapped to EL2:

**AArch64**:

- Non-secure EL1 and EL0 reads of the CTR_EL0, CCSIDR_EL1, CLIDR_EL1, and CSSELR_EL1.
- Non-secure EL1 and EL0 writes to the CSSELR_EL1.

**AArch32**:

- Non-secure PL1 and PL0 reads of the CTR, CCSIDR, CLIDR, and CSSELR.
- Non-secure PL1 and PL0 writes to the CSSELR.

0: EL0 and EL1 using AArch64: Non-secure EL0 and EL1 accesses to the CSSELR_EL1 register are not trapped to EL2.
EL0 and EL1 using AArch64: Non-secure EL0 and EL1 read accesses to the CTR_EL0, CCSIDR_EL1, and CLIDR_EL1 registers are not trapped to EL2.
PL0 and PL1 using AArch32: Non-secure PL0 and PL1 accesses to the CSSELR register are not trapped to EL2.
PL0 and PL1 using AArch32: Non-secure PL0 and PL1 read accesses to the CTR, CCSIDR, and CLIDR registers are not trapped to EL2.

1
EL0 and EL1 using AArch64: Non-secure EL0 and EL1 accesses to the CSSELR_EL1 register are trapped to EL2.
EL0 and EL1 using AArch64: Non-secure EL0 and EL1 read accesses to the CTR_EL0, CCSIDR_EL1, and CLIDR_EL1 registers are trapped to EL2.
PL0 and PL1 using AArch32: Non-secure PL0 and PL1 accesses to the CSSELR register are trapped to EL2.
PL0 and PL1 using AArch32: Non-secure PL0 and PL1 read accesses to the CTR, CCSIDR, and CLIDR registers are trapped to EL2.

TID1, bit [16]
Trap ID group 1. When set to 1, Non-secure EL1 reads of the following registers are trapped to EL2:
AArch64: REVIDR_EL1, AIDR_EL1.
AArch32: TCMTR, TLBTR, REVIDR, AIDR.

0
EL1 using AArch64: Non-secure EL1 read accesses to the REVIDR_EL1 and AIDR_EL1 registers are not trapped to EL2.
EL1 using AArch32: Non-secure EL1 read accesses to the TCMTR, TLBTR, and REVIDR, AIDR registers are not trapped to EL2.

1
EL1 using AArch64: Non-secure EL1 read accesses to the REVIDR_EL1 and AIDR_EL1 registers are trapped to EL2.
EL1 using AArch32: Non-secure EL1 read accesses to the TCMTR, TLBTR, and REVIDR, AIDR registers are trapped to EL2.

TID0, bit [15]
Trap ID group 0. When set to 1, the following register accesses are trapped to EL2:
AArch64: None.
AArch32:
• Non-secure EL1 and EL0 reads of the JIDR.
• Non-secure EL1 reads of the FPSID.

Note
• The FPSID is not accessible at EL0 using AArch32.
• When the FPSID is accessible, a T32 or A32 VMSR FPSID, <Rt> instruction is permitted but is ignored. The execution of this instruction is not trapped by this trap.

0
EL0 and EL1 using AArch32: Non-secure EL0 and EL1 read accesses to the JIDR register are not trapped to EL2.
EL1 using AArch32: Non-secure EL1 read accesses to the FPSID register are not trapped to EL2.

1
EL0 and EL1 using AArch32: Non-secure EL0 and EL1 read accesses to the JIDR register are trapped to EL2.
EL1 using AArch32: Non-secure EL1 read accesses to the FPSID register are trapped to EL2.

TWE, bit [14]
Traps Non-secure EL0 and EL1 execution of WFE instructions to EL2, from both Execution states.
0
Non-secure EL0 or EL1 execution of WFE instructions is not trapped to EL2.
Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

**TWI, bit [13]**

Traps Non-secure EL0 and EL1 execution of WFI instructions to EL2, from both Execution states.

- **0** Non-secure EL0 or EL1 execution of WFI instructions is not trapped to EL2.
- **1** Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

**DC, bit [12]**

Default Cacheable. When this bit is set to 1, this causes:

- The SCTLR_EL1.M bit to behave as 0 when in the Non-secure state for all purposes other than reading the value of the bit.
- The HCR_EL2.VM bit to behave as 1 when in the Non-secure state for all purposes other than reading the value of the bit.
- The memory type produced by the first stage the EL1&0 translation regime is Normal Non-Shareable, Inner WriteBack Read-WriteAllocate, Outer WriteBack Read-WriteAllocate.

When this bit is 0 and the stage 1 MMU is disabled, the default memory attribute for Data accesses is Device-nGnRnE.

This bit is permitted to be cached in a TLB.

**BSU, bits [11:10]**

Barrier Shareability upgrade. The value in this field determines the minimum shareability domain that is applied to any barrier executed from Non-secure EL1 or EL0:

- **00** No effect
- **01** Inner Shareable
- **10** Outer Shareable
- **11** Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

**FB, bit [9]**

Force broadcast. When this bit is set to 1, this causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:
AArch32: BPIALL, TLBIALL, TLBIMVA, TLBISID, DTLBIALL, DTLBIMVA, DTLBISID, ITLBIALL, ITLBIMVA, ITLBISID, TLBIMVAA, ICIALLU, TLBIMVAL, TLBIMVAAL.
AArch64: TLB VMA LLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1, IC IALLU.

VSE, bit [8]
Virtual System Error/Asynchronous Abort.
0 Virtual System Error/Asynchronous Abort is not pending by this mechanism.
1 Virtual System Error/Asynchronous Abort is pending by this mechanism.

The virtual System Error/Asynchronous Abort is only enabled when the HCR_EL2.AMO bit is set.

VI, bit [7]
Virtual IRQ Interrupt.
0 Virtual IRQ is not pending by this mechanism.
1 Virtual IRQ is pending by this mechanism.

The virtual IRQ is only enabled when the HCR_EL2.IMO bit is set.

VF, bit [6]
Virtual FIQ Interrupt.
0 Virtual FIQ is not pending by this mechanism.
1 Virtual FIQ is pending by this mechanism.

The virtual FIQ is only enabled when the HCR_EL2.FMO bit is set.

AMO, bit [5]
Asynchronous External Abort and SError Interrupt routing.
0 When executing at Non-secure Exception levels below EL2, physical Asynchronous External Aborts and SError Interrupts are not taken to EL2.
When executing at EL2 using AArch64, physical Asynchronous External Aborts and SError Interrupts are not taken unless they are routed to EL3 by the SCR_EL3.EA bit.
Virtual Asynchronous External Aborts and SError Interrupts interrupts are disabled.
1 When executing at any Exception level in Non-secure state, physical Asynchronous External Aborts and SError Interrupts are taken to EL2 unless they are routed to EL3.
Virtual Asynchronous External Aborts and SError Interrupts are enabled in Non-secure state.

For more information, see Asynchronous exception routing on page D1-1553.

IMO, bit [4]
Physical IRQ Routing.
0 When executing at Non-secure Exception levels below EL2, physical IRQ interrupts are not taken to EL2.
When executing at EL2 using AArch64, physical IRQ interrupts are not taken unless they are routed to EL3 by the SCR_EL3.IRQ bit.
Virtual IRQ interrupts are disabled.
1 When executing at any Exception level in Non-secure state, physical IRQ interrupts are taken to EL2 unless they are routed to EL3.
Virtual IRQ interrupts are enabled in Non-secure state.

For more information, see Asynchronous exception routing on page D1-1553.

FMO, bit [3]
Physical FIQ Routing.
0 When executing at Non-secure Exception levels below EL2, physical FIQ interrupts are not taken to EL2.
When executing at EL2 using AArch64, physical FIQ interrupts are not taken unless they are routed to EL3 by the SCR_EL3.FIQ bit. Virtual FIQ interrupts are disabled.

1 When executing at any Exception level in Non-secure state, physical FIQ interrupts are taken to EL2 unless they are routed to EL3. Virtual FIQ interrupts are enabled in Non-secure state.

For more information, see *Asynchronous exception routing on page D1-1553.*

**PTW, bit [2]**

Protected Table Walk. In the Non-secure EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access can be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

- **0** The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
- **1** The memory access generates a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

**SWIO, bit [1]**

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to be treated as data cache clean and invalidate by set/way:

- **0** Has no effect on the operation of data cache invalidate by set/way instructions.
- **1** Data cache invalidate by set/way instructions operate as data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch32: DCISW is executed as DCCISW.
AArch64: DC ISW is executed as DC CISW.

This bit can be implemented as RES1.

**VM, bit [0]**

Virtualization MMU enable for Non-secure EL1&0 stage 2 address translation. Possible values of this bit are:

- **0** EL1&0 stage 2 address translation disabled.
- **1** EL1&0 stage 2 address translation enabled.

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 operate as data cache clean and invalidate instructions. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR_EL2.SWIO bit.

This bit is permitted to be cached in a TLB.

### Accessing the HCR_EL2:

To access the HCR_EL2:

- **MRS <Xt>, HCR_EL2**; Read HCR_EL2 into Xt
- **MSR HCR_EL2, <Xt>**; Write Xt to HCR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.34  HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose
Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

Traps and Enables
There are no traps or enables affecting this register.

Configurations
AArch64 System register HPFAR_EL2[31:0] is architecturally mapped to AArch32 System register HPFAR.
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes
HPFAR_EL2 is a 64-bit register.

Field descriptions
The HPFAR_EL2 bit assignments are:

![bit assignments diagram]

bits [63:40]:
Reserved, RES0.

FIPA[47:12], bits [39:4]:
Bits [47:12] of the faulting intermediate physical address. For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.
The HPFAR_EL2 is written for:
\[\text{Translation or Access faults in the second stage of translation.}\]
\[\text{An abort in the second stage of translation performed during the translation table walk of a first stage translation, caused by a Translation fault, an Access flag fault, or a Permission fault.}\]
\[\text{A stage 2 Address size fault.}\]
--- Note ---

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

For all other exceptions taken to EL2, this register is UNKNOWN.

**Bits [3:0]**

Reserved, RES0.

**Accessing the HPFAR_EL2:**

To access the HPFAR_EL2:

MRS <Xt>, HPFAR_EL2 ; Read HPFAR_EL2 into Xt
MSR HPFAR_EL2, <Xt> ; Write Xt to HPFAR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0110</td>
<td>0000</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.2.35  HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower in AArch32, to the CP15 primary coprocessor registers, \{c0-c3,c5-c13,c15\} using MCR, MRC, MCRR, and MRRC instructions.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register HSTR_EL2 is architecturally mapped to AArch32 System register HSTR. If EL2 is not implemented, this register is RES0 from EL3. If no Exception level can use AArch32, then this register is RES0 RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

HSTR_EL2 is a 32-bit register.

**Field descriptions**

The HSTR_EL2 bit assignments are:

```
 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
RES0 T10 T09 T08 T07 T06 T05 T04 T03 T02 T01 T00
```

**Bits [31:16]**

Reserved, RES0.

**T<n>, bit [n], for n = 0 to 15**

HSTR_EL2,\{T0-T3, T5-T13, T15\} trap Non-secure EL1 or EL0 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the CP15 System registers, by the accessed primary CP15 register number, \{c0-c3, c5-c13, c15\}, when EL1 or EL0 is using AArch32.

0  Non-secure EL0 or EL1 accesses, from AArch32, to the corresponding CP15 System registers are not trapped to EL2.
Any Non-secure EL1 MCR, MRC, MCRR, or MRRC access, from AArch32, to a corresponding register is trapped to EL2.

A Non-secure EL0 MCR, MRC, MCRR, or MRRC access, from AArch32, to the corresponding CP15 System register is trapped to EL2 only if it is not undefined when this bit is zero.

The primary CP15 register number is the value of \(<CRn>\) for an MCR or MRC instruction, or the value of \(<CRm>\) for an MCRR or MRRC instruction.

For example, when HSTR_EL2.T7 is 1:

- Any 32-bit CP15 access from a Non-secure EL1 mode using AArch32, using an MCR or MRC instruction with \(<CRn>\) set to c7, is trapped to EL2.
- Any 64-bit CP15 access from a Non-secure EL1 mode using AArch32, using an MCRR or MRRC instruction with \(<CRm>\) set to c7, is trapped to EL2.

Fields T4 and T14 are RES0.

**Accessing the HSTR_EL2:**

To access the HSTR_EL2:

MRS <Xt>, HSTR_EL2 ; Read HSTR_EL2 into Xt
MSR HSTR_EL2, <Xt> ; Write Xt to HSTR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.2.36 ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0

The ID_AA64AFR0_EL1 characteristics are:

**Purpose**

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch64.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

- If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

ID_AA64AFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64AFR0_EL1 bit assignments are:

Reserved, RES0.

**Accessing the ID_AA64AFR1_EL1:**

To access the ID_AA64AFR1_EL1:

MRS <Xt>, ID_AA64AFR1_EL1 ; Read ID_AA64AFR1_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0101</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.2.38  ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch64.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_AA64DFR0_EL1 is architecturally mapped to External register EDDFR.

**Attributes**

ID_AA64DFR0_EL1 is a 64-bit register.

**Field descriptions**

The ID_AA64DFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>28</th>
<th>24</th>
<th>20</th>
<th>16</th>
<th>12</th>
<th>8</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CTX_CMPs</td>
<td>RES0</td>
<td>WRP</td>
<td>RES0</td>
<td>BRP</td>
<td>PMU Ver</td>
<td>Trace Ver</td>
<td>Debug Ver</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**CTX_CMPs, bits [31:28]**

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

**Bits [27:24]**

Reserved, RES0.

**WRPs, bits [23:20]**

Number of watchpoints, minus 1. The value of 0b0000 is reserved.

**Bits [19:16]**

Reserved, RES0.

**BRPs, bits [15:12]**

Number of breakpoints, minus 1. The value of 0b0000 is reserved.
### PMUVer, bits [11:8]

Performance Monitors extension version. Indicates whether system register interface to Performance Monitors extension is implemented. Defined values are:

- **0000**: Performance Monitors extension system registers not implemented.
- **0001**: Performance Monitors extension system registers implemented, PMUv3.
- **1111**: IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

### TraceVer, bits [7:4]

Trace support. Indicates whether system register interface to a trace macrocell is implemented. Defined values are:

- **0000**: Trace macrocell system registers not implemented.
- **0001**: Trace macrocell system registers implemented.

All other values are reserved.

A value of 0000 only indicates that no system register interface to a trace macrocell is implemented. A trace macrocell might nevertheless be implemented without a system register interface.

### DebugVer, bits [3:0]

Debug architecture version. Indicates presence of ARMv8 debug architecture.

- **0110**: ARMv8 debug architecture.

All other values are reserved.

### Accessing the ID_AA64DFR0_EL1:

To access the ID_AA64DFR0_EL1:

```
MRS <Xt>, ID_AA64DFR0_EL1 ; Read ID_AA64DFR0_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0101</td>
<td>00</td>
</tr>
</tbody>
</table>
D7.2.39 ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of top level information about the debug system in AArch64.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0 EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>

</tr>
</tbody>
</table>

Bits [63:20]

Reserved, RES0.

CRC32, bits [19:16]

CRC32 instructions in AArch64. Defined values are:

- 0000  No CRC32 instructions implemented.

All other values are reserved.

SHA2, bits [15:12]

SHA2 instructions in AArch64. Defined values are:

- 0000  No SHA2 instructions implemented.
- 0001  SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.

All other values are reserved.

SHA1, bits [11:8]

SHA1 instructions in AArch64. Defined values are:

- 0000  No SHA1 instructions implemented.
0001  SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.

All other values are reserved.

AES, bits [7:4]

AES instructions in AArch64. Defined values are:

0000  No AES instructions implemented.
0001  AESE, AESD, AESMC, and AESIMC instructions implemented.
0010  As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

Bits [3:0]

Reserved, RES0.

**Accessing the ID_AA64ISAR0_EL1:**

To access the ID_AA64ISAR0_EL1:

MRS <Xt>, ID_AA64ISAR0_EL1 ; Read ID_AA64ISAR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0110</td>
<td>000</td>
</tr>
</tbody>
</table>
### D7.2.41 ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

**Purpose**

Reserved for future expansion of the information about the instructions implemented in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>

D7.2.42 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>

<td>BigEnd</td>
<td>ASIDBits</td>
<td>PARange</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:32]

Reserved, RES0.

TGran4, bits [31:28]

Support for 4KB memory translation granule size. Defined values are:

0000  4KB granule supported.
1111  4KB granule not supported.

All other values are reserved.

TGran64, bits [27:24]

Support for 64KB memory translation granule size. Defined values are:

0000  64KB granule supported.
1111  64KB granule not supported.

All other values are reserved.

TGran16, bits [23:20]

Support for 16KB memory translation granule size. Defined values are:

0000  16KB granule not supported.
0001 16KB granule supported.
All other values are reserved.

**BigEndEL0, bits [19:16]**
Mixed-endian support at EL0 only. Defined values are:
- 0000 No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.
- 0001 Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.
All other values are reserved.
This field is invalid and is RES0 if the BigEnd field, bits [11:8], is not 0000.

**SNSMem, bits [15:12]**
Secure versus Non-secure Memory distinction. Defined values are:
- 0000 Does not support a distinction between Secure and Non-secure Memory.
- 0001 Does support a distinction between Secure and Non-secure Memory.
All other values are reserved.

**BigEnd, bits [11:8]**
Mixed-endian configuration support. Defined values are:
- 0000 No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.
- 0001 Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.
All other values are reserved.

**ASIDBits, bits [7:4]**
Number of ASID bits. Defined values are:
- 0000 8 bits.
- 0010 16 bits.
All other values are reserved.

**PARange, bits [3:0]**
Physical Address range supported. Defined values are:
- 0000 32 bits, 4GB.
- 0001 36 bits, 64GB.
- 0010 40 bits, 1TB.
- 0011 42 bits, 4TB.
- 0100 44 bits, 16TB.
- 0101 48 bits, 256TB.
All other values are reserved.

**Accessing the ID_AA64MMFR0_EL1:**
To access the ID_AA64MMFR0_EL1:

MRS <Xt>, ID_AA64MMFR0_EL1 ; Read ID_AA64MMFR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>

</tr>
</tbody>
</table>

Bits [63:28]

Reserved, RES0.

GIC, bits [27:24]

System register GIC interface. Defined values are:

- 0000  No System register interface to the GIC is supported.
- 0001  System register interface to the GIC CPU interface is supported.

All other values are reserved.

AdvSIMD, bits [23:20]

Advanced SIMD. Defined values are:

- 0000  Advanced SIMD is implemented.
- 1111  Advanced SIMD is not implemented.

All other values are reserved.

FP, bits [19:16]

Floating-point. Defined values are:

- 0000  Floating-point is implemented.
1111 Floating-point is not implemented.
All other values are reserved.

**EL3, bits [15:12]**
EL3 Exception level handling. Defined values are:
0000 EL3 is not implemented.
0001 EL3 can be executed in AArch64 state only.
0010 EL3 can be executed in either AArch64 or AArch32 state.
All other values are reserved.

**EL2, bits [11:8]**
EL2 Exception level handling. Defined values are:
0000 EL2 is not implemented.
0001 EL2 can be executed in AArch64 state only.
0010 EL2 can be executed in either AArch64 or AArch32 state.
All other values are reserved.

**EL1, bits [7:4]**
EL1 Exception level handling. Defined values are:
0001 EL1 can be executed in AArch64 state only.
0010 EL1 can be executed in either AArch64 or AArch32 state.
All other values are reserved.

**EL0, bits [3:0]**
EL0 Exception level handling. Defined values are:
0001 EL0 can be executed in AArch64 state only.
0010 EL0 can be executed in either AArch64 or AArch32 state.
All other values are reserved.

**Accessing the ID_AA64PFR0_EL1:**
To access the ID_AA64PFR0_EL1:

MRS <Xt>, ID_AA64PFR0_EL1 ; Read ID_AA64PFR0_EL1 into Xt

Register access is encoded as follows:

**Accessing the ID_AFR0_EL1:**

To access the ID_AFR0_EL1:

MRS <Xt>, ID_AFR0_EL1 ; Read ID_AFR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.2.47  ID_DFR0_EL1, AArch32 Debug Feature Register 0

The ID_DFR0_EL1 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with the Main ID Register, MIDR_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_DFR0_EL1 is architecturally mapped to AArch32 System register ID_DFR0.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_DFR0_EL1 is a 32-bit register.

**Field descriptions**

The ID_DFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:28]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Reserved, res0.</td>
</tr>
<tr>
<td>PerfMon</td>
<td>Performance Monitors. Support for coprocessor-based ARM Performance Monitors Extension, for A and R profile processors. Defined values are:</td>
</tr>
<tr>
<td></td>
<td>0000 - Performance Monitors Extension system registers not implemented.</td>
</tr>
<tr>
<td></td>
<td>0001 - Support for Performance Monitors Extension version 1 (PMUv1) system registers.</td>
</tr>
<tr>
<td></td>
<td>0010 - Support for Performance Monitors Extension version 2 (PMUv2) system registers.</td>
</tr>
<tr>
<td></td>
<td>0011 - Support for Performance Monitors Extension version 3 (PMUv3) system registers.</td>
</tr>
<tr>
<td></td>
<td>1111 - IMPLEMENTATION DEFINED form of Performance Monitors system registers supported. PMUv3 not supported.</td>
</tr>
<tr>
<td></td>
<td>All other values are reserved.</td>
</tr>
<tr>
<td></td>
<td>In ARMv8-A the permitted values are 0000, 0011, and 1111.</td>
</tr>
</tbody>
</table>
In ARMv7, the value 0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an ARMv8 implementation.

MProfDbg, bits [23:20]
M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:
- 0000  Not supported.
- 0001  Support for M profile Debug architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

MMapTrc, bits [19:16]
Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:
- 0000  Not supported.
- 0001  Support for ARM trace architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A the permitted values are 0000, and 0001.
In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]
Coprocessor Trace. Support for coprocessor-based trace model. Defined values are:
- 0000  Not supported.
- 0001  Support for ARM trace architecture, with CP14 access.
All other values are reserved.
In ARMv8-A the permitted values are 0000, and 0001.
In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]
Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.
In ARMv8-A this field is RES0.
The optional memory map defined by ARMv8 is not compatible with ARMv7.

CopSDbg, bits [7:4]
Coprocessor Secure Debug. Support for a Secure debug model accessed through a conceptual coprocessor, for an A profile processor that includes EL3.
If EL3 is not implemented and the implemented Security state is Non-Secure state, this field is RES0.
Otherwise, this field reads the same as bits [3:0].

CopDbg, bits [3:0]
Coprocessor Debug. Support for coprocessor based debug model, for A and R profile processors. Defined values are:
- 0000  Not supported.
- 0010  Support for ARMv6, v6 Debug architecture, with CP14 access.
- 0011  Support for ARMv6, v6.1 Debug architecture, with CP14 access.
- 0100  Support for ARMv7, v7 Debug architecture, with CP14 access.
- 0101  Support for ARMv7, v7.1 Debug architecture, with CP14 access.
- 0110  Support for ARMv8 debug architecture, with CP14 access.
All other values are reserved.
In ARMv8-A the permitted values are 0000, and 0110.
Accessing the ID_DFR0_EL1:

To access the ID_DFR0_EL1:

MRS <Xt>, ID_DFR0_EL1; Read ID_DFR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>

</tbody>
</table>
ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0

The ID_ISAR0_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

AArch64 System register ID_ISAR0_EL1 is architecturally mapped to AArch32 System register ID_ISAR0.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR0_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Divide</td>
<td>Debug</td>

<td>CmpBranch</td>
<td>BitField</td>
<td>BitCount</td>
<td>Swap</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:28]

Reserved, RES0.

Divide, bits [27:24]

Indicates the implemented Divide instructions. Defined values are:

0000 None implemented.

0001 Adds SDIV and UDIV in the T32 instruction set.

0010 As for 0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Debug, bits [23:20]

Indicates the implemented Debug instructions. Defined values are:

0000 None implemented.
0001  Adds BKPT.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

Coproc, bits [19:16]
Indicates the implemented Coprocessor instructions. Defined values are:
0000  None implemented, except for instructions separately attributed by the architecture, including CP15, CP14, and Advanced SIMD and VFP.
0001  Adds generic CDP, LDC, MCR, MRC, and STC.
0010  As for 0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.
0011  As for 0010, and adds generic MCRR and MRRC.
0100  As for 0011, and adds generic MCRR2 and MRRC2.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

CmpBranch, bits [15:12]
Indicates the implemented combined Compare and Branch instructions in the T32 instruction set. Defined values are:
0000  None implemented.
0001  Adds CBNZ and CBZ.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

BitField, bits [11:8]
Indicates the implemented BitField instructions. Defined values are:
0000  None implemented.
0001  Adds BFC, BFI, SBFX, and UBFX.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

BitCount, bits [7:4]
Indicates the implemented Bit Counting instructions. Defined values are:
0000  None implemented.
0001  Adds CLZ.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

Swap, bits [3:0]
Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:
0000  None implemented.
0001  Adds SWP and SWPB.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

Accessing the ID_ISAR0_EL1:
To access the ID_ISAR0_EL1:
MRS <Xt>, ID_ISAR0_EL1 ; Read ID_ISAR0_EL1 into Xt
Register access is encoded as follows:

</table>
D7.2.49 ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1

The ID_ISAR1_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_ISAR1_EL1 is architecturally mapped to AArch32 System register ID_ISAR1.

In an AArch64-only implementation, this register is **UNKNOWN**.

**Attributes**

ID_ISAR1_EL1 is a 32-bit register.

**Field descriptions**

The ID_ISAR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jazelle</td>
<td>Interwork</td>
<td>Immediate</td>
<td>IfThen</td>
<td>Extend</td>
<td>Except_AR</td>
<td>Except</td>
<td>Endian</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Jazelle, bits [31:28]**

Indicates the implemented Jazelle extension instructions. Defined values are:

- 0000  No support for Jazelle.
- 0001  Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**Interwork, bits [27:24]**

Indicates the implemented Interworking instructions. Defined values are:

- 0000  None implemented.
- 0001  Adds the BX instruction, and the T bit in the PSR.
- 0010  As for 0001, and adds the BLX instruction. PC loads have BX-like behavior.
As for 0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

Immediate, bits [23:20]

Indicates the implemented data-processing instructions with long immediates. Defined values are:

0000  None implemented.
0001  Adds:
     • The MOVT instruction.
     • The MOV instruction encodings with zero-extended 16-bit immediates.
     • The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

IfThen, bits [19:16]

Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:

0000  None implemented.
0001  Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Extend, bits [15:12]

Indicates the implemented Extend instructions. Defined values are:

0000  No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
0001  Adds the SXTB, SXTH, UXTB, and UXTH instructions.
0010  As for 0001, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Except_AR, bits [11:8]

Indicates the implemented A and R profile exception-handling instructions. Defined values are:

0000  None implemented.
0001  Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Except, bits [7:4]

Indicates the implemented exception-handling instructions in the ARM instruction set. Defined values are:

0000  Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
0001  Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Endian, bits [3:0]**

Indicates the implemented Endian instructions. Defined values are:

- 0000: None implemented.
- 0001: Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

**Accessing the ID_ISAR1_EL1:**

To access the ID_ISAR1_EL1:

```
MRS <Xt>, ID_ISAR1_EL1 ; Read ID_ISAR1_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.50  ID_ISAR2_EL1, AArch32 Instruction Set Attribute Register 2

The ID_ISAR2_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

AArch64 System register ID_ISAR2_EL1 is architecturally mapped to AArch32 System register ID_ISAR2.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR2_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reversal</td>
<td>PSR_AR</td>
<td>MultU</td>
<td>MultS</td>
<td>Mult</td>
<td>MemHint</td>
<td>LoadStore</td>
<td>MultiAccessInt</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Reversal, bits [31:28]

Indicates the implemented Reversal instructions. Defined values are:

- 0000  None implemented.
- 0001  Adds the REV, REV16, and REVSH instructions.
- 0010  As for 0001, and adds the RBIT instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

PSR_AR, bits [27:24]

Indicates the implemented A and R profile instructions to manipulate the PSR. Defined values are:

- 0000  None implemented.
0001 Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

The exception return forms of the data-processing instructions are:
- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

**MultU, bits [23:20]**

Indicates the implemented advanced unsigned Multiply instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the UMULL and UMLAL instructions.
- 0010 As for 0001, and adds the UMAAL instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

**MultS, bits [19:16]**

Indicates the implemented advanced signed Multiply instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the SMULL and SMLAL instructions.
- 0010 As for 0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.
- 0011 As for 0010, and adds the SMLAD, SMLADX, SMLADL, SMLADLT, SMLSD, SMLSDX, SMLSLD, SMLSLDX, SMMLA, SMMLAR, SMMLS, SMMLSR, SMMLUL, SMMLUR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

**Mult, bits [15:12]**

Indicates the implemented additional Multiply instructions. Defined values are:

- 0000 No additional instructions implemented. This means only MUL is implemented.
- 0001 Adds the MLA instruction.
- 0010 As for 0001, and adds the MLS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

**MultiAccessInt, bits [11:8]**

Indicates the support for interruptible multi-access instructions. Defined values are:

- 0000 No support. This means the LDM and STM instructions are not interruptible.
- 0001 LDM and STM instructions are restartable.
- 0010 LDM and STM instructions are continuable.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.
MemHint, bits [7:4]
Indicates the implemented Memory Hint instructions. Defined values are:

- 0000: None implemented.
- 0001: Adds the PLD instruction.
- 0010: Adds the PLD instruction. (0001 and 0010 have identical effects.)
- 0011: As for 0001 (or 0010), and adds the PLI instruction.
- 0100: As for 0011, and adds the PLD instruction.

All other values are reserved.
In ARMv8-A the only permitted value is 0100.

LoadStore, bits [3:0]
Indicates the implemented additional load/store instructions. Defined values are:

- 0000: No additional load/store instructions implemented.
- 0001: Adds the LDRD and STRD instructions.
- 0010: As for 0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR2_EL1:
To access the ID_ISAR2_EL1:

MRS <Xt>, ID_ISAR2_EL1 ; Read ID_ISAR2_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.51  ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3

The ID_ISAR3_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

AArch64 System register ID_ISAR3_EL1 is architecturally mapped to AArch32 System register ID_ISAR3.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR3_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR3_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>T32EE</td>
<td>TrueNOP</td>
<td>T32Copy</td>
<td>TabBranch</td>
<td>SynchPrim</td>
<td>SVC</td>
<td>SIMD</td>
<td>Saturate</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

T32EE, bits [31:28]

Indicates the implemented T32EE instructions. Defined values are:

0000  None implemented.
0001  Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

TrueNOP, bits [27:24]

Indicates the implemented True NOP instructions. Defined values are:

0000  None implemented. This means there are no NOP instructions that do not have any register dependencies.
0001  Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**T32Copy, bits [23:20]**

Indicates the support for T32 non-flag-setting MOV instructions. Defined values are:

- **0000**: Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.
- **0001**: Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**TabBranch, bits [19:16]**

Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:

- **0000**: None implemented.
- **0001**: Adds the TBB and TBH instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**SynchPrin, bits [15:12]**

Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:

- **0000**: If SynchPrim_frac == 0000, no Synchronization Primitives implemented.
- **0001**: If SynchPrim_frac == 0000, adds the LDREX and STREX instructions.
  - If SynchPrim_frac == 0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.
- **0010**: If SynchPrim_frac == 0000, as for [0001, 0011] and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A the only permitted value is 0010.

**SVC, bits [11:8]**

Indicates the implemented SVC instructions. Defined values are:

- **0000**: Not implemented.
- **0001**: Adds the SVC instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**SIMD, bits [7:4]**

Indicates the implemented SIMD instructions. Defined values are:

- **0000**: None implemented.
- **0001**: Adds the SSAT and USAT instructions, and the Q bit in the PSRs.
- **0011**: As for 0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSA16, SSUB16, SSUB8, SSAX, SX16, SX2, SX216, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UX16, UX16, and UX16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.
In ARMv8-A the only permitted value is 0011.
The SIMD field relates only to implemented instructions that perform SIMD operations on the
general-purpose registers. In an implementation that supports floating-point and Advanced SIMD
instructions, MVFR0, MVFR1, and MVFR2 give information about the implemented Advanced
SIMD instructions.

**Saturate, bits [3:0]**
Indicates the implemented Saturate instructions. Defined values are:
- 0000 None implemented. This means no non-Advanced SIMD saturate instructions are
  implemented.
- 0001 Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.
  All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Accessing the ID_ISAR3_EL1:**
To access the ID_ISAR3_EL1:

```assembly
MRS <Xt>, ID_ISAR3_EL1 ; Read ID_ISAR3_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.2.52 ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4

The ID_ISAR4_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR5_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_ISAR4_EL1 is architecturally mapped to AArch32 System register ID_ISAR4.

In an AArch64-only implementation, this register is **UNKNOWN**.

**Attributes**

ID_ISAR4_EL1 is a 32-bit register.

**Field descriptions**

The ID_ISAR4_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SWP_frac</td>
<td>PSR_M</td>
<td>Barrier</td>
<td>SMC</td>
<td>Writeback</td>
<td>WithShifts</td>
<td>Unpriv</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SWP_frac, bits [31:28]**

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:

- **0000**: SWP or SWPB instructions not implemented.
- **0001**: SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the ID_ISAR0.Swap_instrs field is **0000**. In ARMv8-A the only permitted value is **0000**.

**PSR_M, bits [27:24]**

Indicates the implemented M profile instructions to modify the PSRs. Defined values are:

- **0000**: None implemented.
0001  Adds the M profile forms of the CPS, MRS, and MSR instructions.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

**SynchPrim_frac, bits [23:20]**

Used in conjunction with `ID_ISAR3.SynchPrim` to indicate the implemented Synchronization Primitive instructions. Possible values are:

- **0000**  If `SynchPrim` == 0000, no Synchronization Primitives implemented. If `SynchPrim` == 0001, adds the LDREX and STREX instructions. If `SynchPrim` == 0010, also adds the CLREX, LDREXB, LDREXH, STREX, STREXB, STREXH, LDREXD, and STREXD instructions.
- **0011**  If `SynchPrim` == 0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, STREXH instructions.

All other combinations of `SynchPrim` and `SynchPrim_frac` are reserved.
In ARMv8-A the only permitted value is 0000.

**Barrier, bits [19:16]**

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:

- **0000**  None implemented. Barrier operations are provided only as CP15 operations.
- **0001**  Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**SMC, bits [15:12]**

Indicates the implemented SMC instructions. Defined values are:

- **0000**  None implemented.
- **0001**  Adds the SMC instruction.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Writeback, bits [11:8]**

Indicates the support for Writeback addressing modes. Defined values are:

- **0000**  Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
- **0001**  Adds support for all of the writeback addressing modes.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**WithShifts, bits [7:4]**

Indicates the support for instructions with shifts. Defined values are:

- **0000**  Nonzero shifts supported only in MOV and shift instructions.
- **0001**  Adds support for shifts of loads and stores over the range LSL 0-3.
- **0011**  As for 0001, and adds support for other constant shift options, both on load/store and other instructions.
- **0100**  As for 0011, and adds support for register-controlled shift options.

All other values are reserved.
In ARMv8-A the only permitted value is 0100.
Unpriv, bits [3:0]

Indicates the implemented unprivileged instructions. Defined values are:

- **0000** None implemented. No T variant instructions are implemented.
- **0001** Adds the LDRBT, LDRT, STRBT, and STRT instructions.
- **0010** As for 0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR4_EL1:

To access the ID_ISAR4_EL1:

```asm
MRS <Xt>, ID_ISAR4_EL1 ; Read ID_ISAR4_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.2.53 ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5

The ID_ISAR5_EL1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR4_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_ISAR5_EL1 is architecturally mapped to AArch32 System register ID_ISAR5.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_ISAR5_EL1 is a 32-bit register.

**Field descriptions**

The ID_ISAR5_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CRC32</td>
<td>SHA2</td>
<td>SHA1</td>
<td>AES</td>
<td>SEVL</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:20]**

Reserved, RES0.

**CRC32, bits [19:16]**

Indicates whether CRC32 instructions are implemented in AArch32.

- 0000: No CRC32 instructions implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

**SHA2, bits [15:12]**

Indicates whether SHA2 instructions are implemented in AArch32.

- 0000: No SHA2 instructions implemented.
- 0001: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

**SHA1, bits [11:8]**

Indicates whether SHA1 instructions are implemented in AArch32.

- 0000: No SHA1 instructions implemented.
- 0001: SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

**AES, bits [7:4]**

Indicates whether AES instructions are implemented in AArch32.

- 0000: No AES instructions implemented.
- 0001: AESE, AESD, AESMC, and AESIMC implemented.
- 0010: As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

**SEVL, bits [3:0]**

Indicates whether the SEVL instruction is implemented in AArch32.

- 0000: SEVL is implemented as a NOP.
- 0001: SEVL is implemented as Send Event Local.

In ARMv8-A the only permitted value is 0001.

**Accessing the ID_ISAR5_EL1:**

To access the ID_ISAR5_EL1:

```assembly
MRS <Xt>, ID_ISAR5_EL1 ; Read ID_ISAR5_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.2.54 ID_MMFR0_EL1, AArch32 Memory Model Feature Register 0

The ID_MMFR0_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR1_EL1, ID_MMFR2_EL1, and ID_MMFR3_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_MMFR0_EL1 is architecturally mapped to AArch32 System register ID_MMFR0.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_MMFR0_EL1 is a 32-bit register.

**Field descriptions**

The ID_MMFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>InnerShr</th>
<th>FCSE</th>
<th>AuxReg</th>
<th>TCM</th>
<th>ShareLvl</th>
<th>OuterShr</th>
<th>PMSA</th>
<th>VMSA</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 28 27</td>
<td>24 23</td>
<td>20 19</td>
<td>16 15</td>
<td>12 11</td>
<td>8 7</td>
<td>4 3</td>
<td>0</td>
</tr>
</tbody>
</table>

**InnerShr, bits [31:28]**

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

- 0000  Implemented as Non-cacheable.
- 0001  Implemented with hardware coherency support.
- 1111  Shareability ignored.

All other values are reserved.

In ARMv8-A the permitted values are 0000, 0001, and 1111.

This field is valid only if the implementation distinguishes between Inner Shareable and Outer Shareable, by implementing two levels of shareability, as indicated by the value of the Shareability levels field, bits[15:12].

When the Shareability level field is zero, this field is UNK.
FCSE, bits [27:24]
Indicates whether the implementation includes the FCSE. Defined values are:
0000  Not supported.
0001  Support for FCSE.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

AuxReg, bits [23:20]
Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:
0000  None supported.
0001  Support for Auxiliary Control Register only.
0010  Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.
All other values are reserved.
In ARMv8-A the only permitted value is 0010.

Note
Accesses to unimplemented Auxiliary registers are UNDEFINED.

TCM, bits [19:16]
Indicates support for TCMs and associated DMAs. Defined values are:
0000  Not supported.
0001  Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.
0010  Support for TCM only, ARMv6 implementation.
0011  Support for TCM and DMA, ARMv6 implementation.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

ShareLvl, bits [15:12]
Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:
0000  One level of shareability implemented.
0001  Two levels of shareability implemented.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

OuterShr, bits [11:8]
Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:
0000  Implemented as Non-cacheable.
0001  Implemented with hardware coherency support.
1111  Shareability ignored.
All other values are reserved.
In ARMv8-A the permitted values are 0000, 0001, and 1111.

PMSA, bits [7:4]
Indicates support for a PMSA. Defined values are:
0000  Not supported.
0001  Support for IMPLEMENTATION DEFINED PMSA.
D7 AArch64 System Register Descriptions

D7.2 General system control registers

0010 Support for PMSAv6, with a Cache Type Register implemented.
0011 Support for PMSAv7, with support for memory subsections. ARMv7-R profile.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

VMSA, bits [3:0]

Indicates support for a VMSA. Defined values are:
0000 Not supported.
0001 Support for IMPLEMENTATION DEFINED VMSA.
0010 Support for VMSAv6, with Cache and TLB Type Registers implemented.
0011 Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.
0100 As for 0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.
0101 As for 0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.

In ARMv8-A the only permitted value is 0101.

Accessing the ID_MMFR0_EL1:

To access the ID_MMFR0_EL1:

MRS <Xt>, ID_MMFR0_EL1 ; Read ID_MMFR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.2.55 ID_MMFR1_EL1, AArch32 Memory Model Feature Register 1

The ID_MMFR1_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

**BPred, bits [31:28]**

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

0000 No branch predictor, or no MMU present. Implies a fixed MPU configuration.

0001 Branch predictor requires flushing on:
  - Enabling or disabling the MMU.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Any change to the TTBR0, TTBR1, or TTBCR registers.
  - Changes of FCSE ProcessID or ContextID.

0010 Branch predictor requires flushing on:
  - Enabling or disabling the MMU.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
• Any change to the TTBR0, TTBR1, or TTBCR registers without a corresponding change to the FCSE ProcessID or ContextID.

0011 Branch predictor requires flushing only on writing new data to instruction locations.
0100 For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

In ARMv8-A the only permitted value is 0100.

The branch predictor is described in some documentation as the Branch Target Buffer.

L1TstCln, bits [27:24]
Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

0000 None supported.
0001 Supported Level 1 data cache test and clean operations are:
  • Test and clean data cache.
0010 As for 0001, and adds:
  • Test, clean, and invalidate data cache.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1Uni, bits [23:20]
Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations, for a unified cache implementation. Defined values are:

0000 None supported.
0001 Supported entire Level 1 cache operations are:
  • Invalidate cache, including branch predictor if appropriate.
  • Invalidate branch predictor, if appropriate.
0010 As for 0001, and adds:
  • Clean cache, using a recursive model that uses the cache dirty status bit.
  • Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1Hvd, bits [19:16]
Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations, for a Harvard cache implementation. Defined values are:

0000 None supported.
0001 Supported entire Level 1 cache operations are:
  • Invalidate instruction cache, including branch predictor if appropriate.
  • Invalidate branch predictor, if appropriate.
0010 As for 0001, and adds:
  • Invalidate data cache.
  • Invalidate data cache and instruction cache, including branch predictor if appropriate.
0011 As for 0010, and adds:
  • Clean data cache, using a recursive model that uses the cache dirty status bit.
  • Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1UnlSW, bits [15:12]
Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

0000  None supported.
0001  Supported Level 1 unified cache line maintenance operations by set/way are:
       •  Clean cache line by set/way.
0010  As for 0001, and adds:
       •  Clean and invalidate cache line by set/way.
0011  As for 0010, and adds:
       •  Invalidate cache line by set/way.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1HvdSW, bits [11:8]
Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Defined values are:

0000  None supported.
0001  Supported Level 1 Harvard cache line maintenance operations by set/way are:
       •  Clean data cache line by set/way.
       •  Clean and invalidate data cache line by set/way.
0010  As for 0001, and adds:
       •  Invalidate data cache line by set/way.
0011  As for 0010, and adds:
       •  Invalidate instruction cache line by set/way.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1UnlVA, bits [7:4]
Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Defined values are:

0000  None supported.
0001  Supported Level 1 unified cache line maintenance operations by VA are:
       •  Clean cache line by VA.
       •  Invalidate cache line by VA.
       •  Clean and invalidate cache line by VA.
0010  As for 0001, and adds:
       •  Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1HvdVA, bits [3:0]
Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Defined values are:

0000  None supported.
0001 Supported Level 1 Harvard cache line maintenance operations by VA are:
- Clean data cache line by VA.
- Invalidate data cache line by VA.
- Clean and invalidate data cache line by VA.
- Clean instruction cache line by VA.

0010 As for 0001, and adds:
- Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

**Accessing the ID_MMFR1_EL1:**

To access the ID_MMFR1_EL1:

MRS <Xt>, ID_MMFR1_EL1 ; Read ID_MMFR1_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.2.56  ID_MMFR2_EL1, AArch32 Memory Model Feature Register 2

The ID_MMFR2_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR0_EL1, ID_MMFR1_EL1, and ID_MMFR3_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3=1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_MMFR2_EL1 is architecturally mapped to AArch32 System register ID_MMFR2.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_MMFR2_EL1 is a 32-bit register.

**Field descriptions**

The ID_MMFR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>HWAccFlg</td>
<td>WFIStall</td>
<td>MemBarr</td>
<td>UniTLB</td>
<td>HvdTLB</td>
<td>L1HvdRng</td>
<td>L1HvdBG</td>
<td>L1HvdFG</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**HWAccFlg, bits [31:28]**

Hardware Access Flag. In earlier versions of the ARM Architecture, this field indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Defined values are:

- **0000**: Not supported.
- **0001**: Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

In ARMv8-A the only permitted value is **0000**.

**WFIStall, bits [27:24]**

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:

- **0000**: Not supported.
- **0001**: Support for WFI stalling.

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

MemBarr, bits [23:20]

Memory Barrier. Indicates the supported CP15 memory barrier operations:

0000 None supported.
0001 Supported CP15 Memory barrier operations are:
  • Data Synchronization Barrier (DSB), which in previous versions of the ARM architecture was named Data Write Barrier (DWB).
0010 As for 0001, and adds:
  • Instruction Synchronization Barrier (ISB), which in previous versions of the ARM architecture was called Prefetch Flush.
  • Data Memory Barrier (DMB).

All other values are reserved.
In ARMv8-A the only permitted value is 0010.
ARM deprecates the use of these operations. ID_ISAR4.Barrier_intrs indicates the level of support for the preferred barrier instructions.

UniTLB, bits [19:16]

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:

0000 Not supported.
0001 Supported unified TLB maintenance operations are:
  • Invalidate all entries in the TLB.
  • Invalidate TLB entry by VA.
0010 As for 0001, and adds:
  • Invalidate TLB entries by ASID match.
0011 As for 0010, and adds:
  • Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.
0100 As for 0011, and adds:
  • Invalidate Hyp mode unified TLB entry by VA.
  • Invalidate entire Non-secure PL1&0 unified TLB.
  • Invalidate entire Hyp mode unified TLB.
0101 As for 0100, and adds the following operations: TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, TLBIMVALH.
0110 As for 0101, and adds the following operations: TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, TLBIIPAS2L.

All other values are reserved.
In ARMv8-A the only permitted value is 0110.

HvdTLB, bits [15:12]

If the Unified TLB field (UniTLB, bits [19:16]) is not 0000, then the meaning of this field is IMPLEMENTATION DEFINED. ARM deprecates the use of this field by software.

L1HvdRng, bits [11:8]

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:

0000 Not supported.
0001 Supported Level 1 Harvard cache maintenance range operations are:
- Invalidate data cache range by VA.
- Invalidate instruction cache range by VA.
- Clean data cache range by VA.
- Clean and invalidate data cache range by VA.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

L1HvdBG, bits [7:4]
Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:
- 0000 Not supported.
- 0001 Supported Level 1 Harvard cache background fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1HvdFG, bits [3:0]
Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:
- 0000 Not supported.
- 0001 Supported Level 1 Harvard cache foreground fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

Accessing the ID_MMFR2_EL1:
To access the ID_MMFR2_EL1:

MRS <Xt>, ID_MMFR2_EL1 ; Read ID_MMFR2_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.2.57  ID_MMFR3_EL1, AArch32 Memory Model Feature Register 3

The ID_MMFR3_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR0_EL1, ID_MMFR1_EL1, and ID_MMFR2_EL1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

AArch64 System register ID_MMFR3_EL1 is architecturally mapped to AArch32 System register ID_MMFR3.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_MMFR3_EL1 is a 32-bit register.

Field descriptions

The ID_MMFR3_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supersec</td>
<td>CMemSz</td>
<td>CohWalk</td>
<td>RES0</td>
<td>MaintBcst</td>
<td>BPMaint</td>
<td>CMaintSW</td>
<td>CMaintVA</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Supersec, bits [31:28]

Supersections. On a VMSA implementation, indicates whether Supersections are supported. Defined values are:

0000  Supersections supported.

1111  Supersections not supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 1111.

CMemSz, bits [27:24]

Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are:

0000  4GB, corresponding to a 32-bit physical address range.

0001  64GB, corresponding to a 36-bit physical address range.

0010  1TB or more, corresponding to a 40-bit or larger physical address range.
All other values are reserved.
In ARMv8-A the permitted values are 0000, 0001 and 0010.

**CohWalk, bits [23:20]**
Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Defined values are:
- **0000**: Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks.
- **0001**: Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Bits [19:16]**
Reserved, RES0.

**MaintBest, bits [15:12]**
Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:
- **0000**: Cache, TLB, and branch predictor operations only affect local structures.
- **0001**: Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- **0010**: Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.

**BPMaint, bits [11:8]**
Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:
- **0000**: None supported.
- **0001**: Supported branch predictor maintenance operations are:
  - Invalidate all branch predictors.
- **0010**: As for 0001, and adds:
  - Invalidate branch predictors by VA.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.

**CMaintSW, bits [7:4]**
Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:
- **0000**: None supported.
- **0001**: Supported hierarchical cache maintenance operations by set/way are:
  - Invalidate data cache by set/way.
  - Clean data cache by set/way.
  - Clean and invalidate data cache by set/way.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.
In a unified cache implementation, the data cache operations apply to the unified caches.
CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

0000  None supported.
0001  Supported hierarchical cache maintenance operations by VA are:
  •  Invalidate data cache by VA.
  •  Clean data cache by VA.
  •  Clean and invalidate data cache by VA.
  •  Invalidate instruction cache by VA.
  •  Invalidate all instruction cache entries.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

In a unified cache implementation, the data cache operations apply to the unified caches, and the instruction cache operations are not implemented.

**Accessing the ID_MMFR3_EL1:**

To access the ID_MMFR3_EL1:

MRS <Xt>, ID_MMFR3_EL1 ; Read ID_MMFR3_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.2.58   ID_MMFR4_EL1, AArch32 Memory Model Feature Register 4

The ID_MMFR4_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_MMFR4_EL1 is architecturally mapped to AArch32 System register ID_MMFR4.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_MMFR4_EL1 is a 32-bit register.

**Field descriptions**

The ID_MMFR4_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/WI</td>
<td>RAZ/WI</td>
<td>RAZ/WI</td>
<td>RAZ/WI</td>
<td>RAZ/WI</td>
<td>RAZ/WI</td>
<td>AC2</td>
<td>RAZ/WI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**AC2, bits [7:4]**

Indicates the extension of the ACTLR and HACTLR registers using ACTLR2 and HACTLR2.

0000  ACTLR2 and HACTLR2 are not supported.

0001  ACTLR2 and HACTLR2 are implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

**Accessing the ID_MMFR4_EL1:**

To access the ID_MMFR4_EL1:

MRS <Xt>, ID_MMFR4_EL1 ; Read ID_MMFR4_EL1 into Xt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>110</td>
</tr>
</tbody>
</table>
**D7.2.59 ID_PFR0_EL1, AArch32 Processor Feature Register 0**

The ID_PFR0_EL1 characteristics are:

**Purpose**

Gives top-level information about the instruction sets supported by the PE in AArch32.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_PFR1_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_PFR0_EL1 is architecturally mapped to AArch32 System register ID_PFR0.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_PFR0_EL1 is a 32-bit register.

**Field descriptions**

The ID_PFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>State3</td>
<td>State2</td>
<td>State1</td>
<td>State0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**State3, bits [15:12]**

T32EE instruction set support. Defined values are:

0000 Not implemented.

0001 T32EE instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

**State2, bits [11:8]**

Jazelle extension support. Defined values are:

0000 Not implemented.

0001 Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.

0010 Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

**State1, bits [7:4]**

T32 instruction set support. Defined values are:
- 0000 T32 instruction set not implemented.
- 0001 T32 encodings before the introduction of Thumb-2 technology implemented:
  - All instructions are 16-bit.
  - A BL or BLX is a pair of 16-bit instructions.
  - 32-bit instructions other than BL and BLX cannot be encoded.
- 0011 T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0011.

**State0, bits [3:0]**

A32 instruction set support. Defined values are:
- 0000 A32 instruction set not implemented.
- 0001 A32 instruction set implemented.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Accessing the ID_PFR0_EL1:**

To access the ID_PFR0_EL1:

MRS <Xt>, ID_PFR0_EL1 ; Read ID_PFR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
ID_PFR1_EL1, AArch32 Processor Feature Register 1

The ID_PFR1_EL1 characteristics are:

**Purpose**

Gives information about the AArch32 programmers' model.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_PFR0_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3=1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register ID_PFR1_EL1 is architecturally mapped to AArch32 System register ID_PFR1.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

ID_PFR1_EL1 is a 32-bit register.

**Field descriptions**

The ID_PFR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28 27</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15</th>
<th>12 11</th>
<th>8 7</th>
<th>4 3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>GIC</td>
<td>Virt_frac</td>
<td>Sec_frac</td>
<td>GenTimer</td>
<td>MProgMod</td>
<td>Security</td>
<td>ProgMod</td>
<td>Virtualization</td>
<td></td>
</tr>
</tbody>
</table>

**GIC, bits [31:28]**

System register GIC CPU interface. Defined values are:

- **0000** No System register interface to the GIC CPU interface is supported.
- **0001** System register interface to the GIC CPU interface is supported.

All other values are reserved.

**Virt_frac, bits [27:24]**

Virtualization fractional field. When the Virtualization field is 0000, determines the support for features from the ARMv7 Virtualization Extensions. Defined values are:

- **0000** No features from the ARMv7 Virtualization Extensions are implemented.
- **0001** The following features of the ARMv7 Virtualization Extensions are implemented:
  - The SCR.SIF bit, if EL3 is implemented.
• The modifications to the SCR.AW and SCR.FW bits described in the Virtualization Extensions, if EL3 is implemented.
• The MSR (Banked register) and MRS (Banked register) instructions.
• The ERET instruction.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

--- Note ---
The ID_ISAR registers do not identify whether the instructions added by the Virtualization Extensions are implemented.

Sec_frac, bits [23:20]
Security fractional field. When the Security field is 0000, determines the support for features from the ARMv7 Security Extensions. Defined values are:

0000 No features from the ARMv7 Security Extensions are implemented.
0001 The following features from the ARMv7 Security Extensions are implemented:
  • The VBAR register.
  • The TTBCR.PD0 and TTBCR.PD1 bits.
0010 As for 0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.
In ARMv8-A the permitted values are 0001 and 0010.

GenTimer, bits [19:16]
Generic Timer support. Defined values are:

0000 Not implemented.
0001 Generic Timer implemented.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

Virtualization, bits [15:12]
Virtualization support. Defined values are:

0000 EL2, Hyp mode, and the HVC instruction not implemented.
0001 EL2, Hyp mode, the HVC instruction, and all the features described by Virt_frac == 0001 implemented.

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

--- Note ---
The ID ISARs do not identify whether the HVC instruction is implemented.

MProgMod, bits [11:8]
M profile programmers' model support. Defined values are:

0000 Not supported.
0010 Support for two-stack programmers' model.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.
Security, bits [7:4]

Security support. Defined values are:

0000  EL3, Monitor mode, and the SMC instruction not implemented.
0001  EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac == 0001 implemented.
0010  As for 0001, and adds the ability to set the NSACR.RFR bit. Not permitted in ARMv8 as the NSACR.RFR bit is RES0.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:

0000  Not supported.
0001  Supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_PFR1_EL1:

To access the ID_PFR1_EL1:

MRS <Xt>, ID_PFR1_EL1 ; Read ID_PFR1_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>001</td>

</tbody>
</table>
D7.2.61 IFSR32_EL2, Instruction Fault Status Register (EL2)

The IFSR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 IFSR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register IFSR32_EL2 is architecturally mapped to AArch32 System register IFSR.

If EL1 is AArch64 only, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

IFSR32_EL2 is a 32-bit register.

Field descriptions

The IFSR32_EL2 bit assignments are:

When TTBCR.EAE==0:

```
<table>
<thead>
<tr>
<th>31</th>
<th>17</th>
<th>16</th>
<th>15</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

FnV

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 IFAR is valid.

1 IFAR is not valid, and holds an UNKNOWN value.
This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

**Bits [15:13]**

Reserved, RES0.

**ExT, bit [12]**

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

**Bit [11]**

Reserved, RES0.

**FS[4], bit [10]**

See FS[3:0], bits [3:0] for description of the FS field.

**LPAE, bit [9]**

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bits [8:4]**

Reserved, RES0.

**FS[3:0], bits [3:0]**

Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:

<table>

010110  Synchronous external abort on translation table walk, second level
010111  Synchronous external abort on translation table walk, third level
011000  Synchronous parity or ECC error on memory access
011101  Synchronous parity or ECC error on memory access on translation table walk, first level
011110  Synchronous parity or ECC error on memory access on translation table walk, second level
011111  Synchronous parity or ECC error on memory access on translation table walk, third level
100001  Alignment fault
100010  Debug event
110000  TLB conflict abort

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

**Accessing the IFSR32_EL2:**

To access the IFSR32_EL2:

MRS <Xt>, IFSR32_EL2 ; Read IFSR32_EL2 into Xt
MSR IFSR32_EL2, <Xt> ; Write Xt to IFSR32_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>10c</td>
<td>0101</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.62 ISR_EL1, Interrupt Status Register

The ISR_EL1 characteristics are:

**Purpose**

Shows whether an IRQ, FIQ, or SError interrupt is pending. When accessed from EL3, EL2 or Secure EL1, the indicated interrupt is the physical interrupt. When accessed from Non-secure EL1, if the interrupt is virtualized, the indicated interrupt is virtual, otherwise it is physical.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register ISR_EL1 is architecturally mapped to AArch32 System register ISR.

**Attributes**

ISR_EL1 is a 32-bit register.

**Field descriptions**

The ISR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>A</td>
<td>I</td>
<td>F</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:9]**

Reserved, RES0.

**A, bit [8]**

SError pending bit:

0  No pending SError.
1  An SError interrupt is pending.

**I, bit [7]**

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0  No pending IRQ.
1  An IRQ interrupt is pending.

**F, bit [6]**

FIQ pending bit. Indicates whether an FIQ interrupt is pending:

0  No pending FIQ.
1  An FIQ interrupt is pending.

**Bits [5:0]**

Reserved, RES0.
Accessing the ISR_EL1:

To access the ISR_EL1:

MRS <Xt>, ISR_EL1 ; Read ISR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.63 **MAIR_EL1, Memory Attribute Indirection Register (EL1)**

The MAIR_EL1 characteristics are:

**Purpose**

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

MAIR_EL1 is permitted to be cached in a TLB.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register PRRR when TTBCR.EAE==0.

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register MAIR0 when TTBCR.EAE==1.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register NMRR when TTBCR.EAE==0.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register MAIR1 when TTBCR.EAE==1.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

MAIR_EL1 is a 64-bit register.

**Field descriptions**

The MAIR_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>48</th>
<th>47</th>
<th>40</th>
<th>39</th>
<th>32</th>
<th>31</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>

</tbody>
</table>

**Accessing the MAIR_EL3:**

To access the MAIR_EL3:

MRS <Xt>, MAIR_EL3 ; Read MAIR_EL3 into Xt
MSR MAIR_EL3, <Xt> ; Write Xt to MAIR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1010</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.66 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

**Purpose**
Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**
There are no traps or enables affecting this register.

**Configurations**
AArch64 System register MIDR_EL1 is architecturally mapped to AArch32 System register MIDR.
AArch64 System register MIDR_EL1 is architecturally mapped to External register MIDR_EL1.

**Attributes**
MIDR_EL1 is a 32-bit register.

**Field descriptions**
The MIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15</th>
<th>4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Implementer</td>
<td>Variant</td>
<td>PartNum</td>
<td>Revision</td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**
The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>

<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
</tbody>
</table>
D7 AArch64 System Register Descriptions
D7.2 General system control registers

Variant, bits [23:20]
A IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]
The permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>ARMv4</td>
</tr>
<tr>
<td>0010</td>
<td>ARMv4T</td>
</tr>
<tr>
<td>0011</td>
<td>ARMv5 (obsolete)</td>
</tr>
<tr>
<td>0100</td>
<td>ARMv5T</td>
</tr>
<tr>
<td>0101</td>
<td>ARMv5TE</td>
</tr>
<tr>
<td>0110</td>
<td>ARMv5TEJ</td>
</tr>
<tr>
<td>0111</td>
<td>ARMv6</td>
</tr>
</tbody>
</table>
| 1111  | Architectural features are individually identified in the ID_* registers, see Identification registers, functional group on page G4-4232. All other values are reserved.

PartNum, bits [15:4]
A IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]
A IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1:
To access the MIDR_EL1:

MRS <Xt>, MIDR_EL1 ; Read MIDR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.67  MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR_EL1 characteristics are:

**Purpose**

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register MPIDR_EL1 is architecturally mapped to AArch32 System register MPIDR.

The assigned value of the MPIDR.\{Aff2, Aff1, Aff0\} or MPIDR_EL1.\{Aff3, Aff2, Aff1, Aff0\} set of fields of each PE must be unique within the system as a whole.

In a uniprocessor system ARM recommends that each Aff<\text{<n>}> field of this register returns a value of 0.

**Attributes**

MPIDR_EL1 is a 64-bit register.

**Field descriptions**

The MPIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, \text{RES0}.</td>
</tr>
<tr>
<td>40</td>
<td>Reserved, \text{RES0}.</td>
</tr>
<tr>
<td>39</td>
<td>Aff3, \text{bits [39:32]}</td>
</tr>
<tr>
<td>32</td>
<td>Affinity level 3. Highest level affinity field.</td>
</tr>
<tr>
<td>31</td>
<td>Reserved, \text{RES1}.</td>
</tr>
<tr>
<td>30</td>
<td>U, \text{bit [30]}</td>
</tr>
<tr>
<td>29</td>
<td>Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:</td>
</tr>
<tr>
<td>25</td>
<td>0 Processor is part of a multiprocessor system.</td>
</tr>
<tr>
<td>24</td>
<td>1 Processor is part of a uniprocessor system.</td>
</tr>
<tr>
<td>15</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>
Bits [29:25]  
Reserved, RES0.

MT, bit [24]  
Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. The possible values of this bit are:
0  Performance of PEs at the lowest affinity level is largely independent.
1  Performance of PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]  
Affinity level 2. Second highest level affinity field.

Aff1, bits [15:8]  
Affinity level 1. Third highest level affinity field.

Aff0, bits [7:0]  
Affinity level 0. Lowest level affinity field.

Accessing the MPIDR_EL1:
To access the MPIDR_EL1:

MRS <Xt>, MPIDR_EL1 ; Read MPIDR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.2.68  MVFR0_EL1, AArch32 Media and VFP Feature Register 0

The MVFR0_EL1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register MVFR0_EL1 is architecturally mapped to AArch32 System register MVFR0.

In an AArch64-only implementation, this register is UNKNOWN.

**Attributes**

MVFR0_EL1 is a 32-bit register.

**Field descriptions**

The MVFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPRound</td>
<td>FPShVec</td>
<td>FPSqrt</td>
<td>FPDive</td>
<td>FPTrap</td>
<td>FPDP</td>
<td>FPSP</td>
<td>SIMDReg</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**FPRound, bits [31:28]**

Floating-Point Rounding modes. Indicates the rounding modes supported by the VFP floating-point hardware. Defined values are:

0000    Only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting.

0001    All rounding modes supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**FPShVec, bits [27:24]**

Short Vectors. Indicates the hardware support for ARMv6 VFP short vectors. Defined values are:

0000    Short vectors not supported.

0001    Short vector operation supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.
FPSqrt, bits [23:20]
Square Root. Indicates the hardware support for the ARMv6 VFP square root operations. Defined values are:

- 0000  Not supported in hardware.
- 0001  Supported.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.
The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPDivide, bits [19:16]
Indicates the hardware support for VFP divide operations. Defined values are:

- 0000  Not supported in hardware.
- 0001  Supported.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.
The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPTrap, bits [15:12]
Floating Point Exception Trapping. Indicates whether the VFP hardware implementation supports exception trapping. Defined values are:

- 0000  Not supported.
- 0001  Supported by the hardware. When exception trapping is supported, support code is needed to handle the trapped exceptions.

All other values are reserved.
A value of 0001 does not indicate that trapped exception handling is available. Because trapped exception handling requires support code, only the support code can provide this information.

FPDP, bits [11:8]
Double Precision. Indicates the hardware support for VFP double-precision operations. Defined values are:

- 0000  Not supported in hardware.
- 0001  Supported, VFPv2.
- 0010  Supported, VFPv3, VFPv4, or ARMv8. VFPv3 and ARMv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.
A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F64 is only available if the Square root field is 0001.
- VDIV.F64 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.
FPSP, bits [7:4]

Single Precision. Indicates the hardware support for VFP single-precision operations. Defined values are:

- \(0000\) Not supported in hardware.
- \(0001\) Supported, VFPv2.
- \(0010\) Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

In ARMv8-A the only permitted value is \(0010\).

A value of \(0b0001\) or \(0b0010\) indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- \(\text{VSQRT.F32}\) is only available if the Square root field is \(0001\).
- \(\text{VDIV.F32}\) is only available if the Divide field is \(0001\).
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates support for the Advanced SIMD register bank. Defined values are:

- \(0000\) Not supported.
- \(0001\) Supported, 16 x 64-bit registers.
- \(0010\) Supported, 32 x 64-bit registers.

All other values are reserved.

In ARMv8-A the permitted values are \(0000\) and \(0010\).

If this field is nonzero:

- All VFP LDC, STC, MCR, and MRC instructions are supported.
- If the MCRR and MRRC instructions are supported then the corresponding VFP instructions are supported.

Accessing the MVFR0_EL1:

To access the MVFR0_EL1:

MRS <Xt>, MVFR0_EL1 ; Read MVFR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.69 MVFR1_EL1, AArch32 Media and VFP Feature Register 1

The MVFR1_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

AArch64 System register MVFR1_EL1 is architecturally mapped to AArch32 System register MVFR1.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

MVFR1_EL1 is a 32-bit register.

Field descriptions

The MVFR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31 28 27</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15</th>
<th>12 11</th>
<th>8 7</th>
<th>4 3</th>

<tbody>
<tr>
<td></td>
<td>FPHP</td>
<td>SIMDHP</td>
<td>SIMDSP</td>
<td>SIMDInt</td>
<td>SIMDLS</td>
<td>FPDNaN</td>
<td>FPfZ</td>
</tr>
</tbody>
</table>

SIMDFMAC

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the floating-point and Advanced SIMD implementation includes the fused multiply accumulate instructions. Defined values are:

0000 Not implemented.

0001 Implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

The floating-point and Advanced SIMD implementations must provide the same level of support for these instructions.

FPHP, bits [27:24]

Floating Point Half Precision. Indicates whether the floating-point implementation provides half-precision floating-point conversion instructions. Defined values are:

0000 Not implemented.
0001  Instructions to convert between half-precision and single-precision implemented.
0010  As for 00001, and also instructions to convert between half-precision and
double-precision implemented.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.

**SIMDHP, bits [23:20]**
Advanced SIMD Half Precision. Indicates whether the floating-point and Advanced SIMD
implementation provides half-precision floating-point conversion instructions. Defined values are:
0000  Not implemented.
0001  Implemented. This value is permitted only if the SIMDSP field is 0001.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**SIMDSP, bits [19:16]**
Advanced SIMD Single Precision. Indicates whether the floating-point and Advanced SIMD
implementation provides single-precision floating-point instructions. Defined values are:
0000  Not implemented.
0001  Implemented. This value is permitted only if the SIMDInt field is 0001.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**SIMDInt, bits [15:12]**
Advanced SIMD Integer. Indicates whether the floating-point and Advanced SIMD implementation
provides integer instructions. Defined values are:
0000  Not implemented.
0001  Implemented.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**SIMDLS, bits [11:8]**
Advanced SIMD Load/Store. Indicates whether the floating-point and Advanced SIMD implementation
provides load/store instructions. Defined values are:
0000  Not implemented.
0001  Implemented.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**FPDNaN, bits [7:4]**
Default NaN mode. Indicates whether the VFP hardware implementation supports only the Default
NaN mode. Defined values are:
0000  Hardware supports only the Default NaN mode.
0001  Hardware supports propagation of NaN values.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**FPFtZ, bits [3:0]**
Flush to Zero mode. Indicates whether the VFP hardware implementation supports only the
Flush-to-Zero mode of operation. Defined values are:
0000  Hardware supports only the Flush-to-Zero mode of operation.
0001 Hardware supports full denormalized number arithmetic.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Accessing the MVFR1_EL1:**

To access the MVFR1_EL1:

MRS <Xt>, MVFR1_EL1 ; Read MVFR1_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>

D7.2.70 MVFR2_EL1, AArch32 Media and VFP Feature Register 2

The MVFR2_EL1 characteristics are:

Purpose
Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID3==1, Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations
AArch64 System register MVFR2_EL1 is architecturally mapped to AArch32 System register MVFR2.
In an AArch64-only implementation, this register is UNKNOWN.

Attributes
MVFR2_EL1 is a 32-bit register.

Field descriptions
The MVFR2_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>FPMisc</td>
<td>SIMDMisc</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]
Reserved, RES0.

FPMisc, bits [7:4]
Indicates support for miscellaneous VFP features.

- 0000: No support for miscellaneous features.
- 0001: Support for Floating-point selection.
- 0010: As 0001, and Floating-point Conversion to Integer with Directed Rounding modes.
- 0011: As 0010, and Floating-point Round to Integral Floating-point.
- 0100: As 0011, and Floating-point MaxNum and MinNum.
All other values are reserved.
In ARMv8-A the only permitted value is 0100.

SIMDMisc, bits [3:0]
Indicates support for miscellaneous Advanced SIMD features.

- 0000: No support for miscellaneous features.
0001  Floating-point Conversion to Integer with Directed Rounding modes.
0010  As 0001, and Floating-point Round to Integral Floating-point.
0011  As 0010, and Floating-point MaxNum and MinNum.
      All other values are reserved.
      In ARMv8-A the only permitted value is 0011.

**Accessing the MVFR2_EL1:**

To access the MVFR2_EL1:

```assembly
MRS <Xt>, MVFR2_EL1 ; Read MVFR2_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0011</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.71 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

**Purpose**

Returns the output address from any address translation operation.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

On a successful conversion, the PAR_EL1 can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- The ATTR and SH fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors.
- See the NS bit description for constraints on the value it returns.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register PAR_EL1 is architecturally mapped to AArch32 System register PAR. RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PAR_EL1 is a 64-bit register.

**Field descriptions**

The PAR_EL1 bit assignments are:

**For all register layouts:**

**F**, bit [0]

When updating the PAR with the result of a translation operation, this bit indicates whether the conversion completed successfully.

- 0 The address translation operation completed successfully.
- 1 The address translation operation aborted.

Hardware does not interpret this bit in any way, and therefore software can set this bit to 0 or 1 without affecting operation.

**When PAR_EL1.F==0:**

```
63 56 55 48 47 12 11 10 9 8 7 6 1 0
   |   |   |   |   | NS | SH | RES0 | F
   ATTR | RES0 | PA |     |     |     |     |
```

IMP DEF
RES1
ATTR, bits [63:56]
Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR_EL1, MAIR_EL2, and MAIR_EL3.
See the Usage constraints for more information about the value returned.

Bits [55:48]
Reserved, RES0.

PA, bits [47:12]
Output address. The output address corresponding to the supplied virtual address. This field returns address bits[47:12].

Bit [11]
Reserved, RES1.

IMP DEF, bit [10]
IMPLEMENTATION DEFINED.

NS, bit [9]
Non-secure. The NS attribute for a translation table entry from a Secure translation regime.
For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.
For a result from a Non-secure translation regime, this bit is UNKNOWN.

SH, bits [8:7]
Shareability attribute, for the returned output address. Permitted values are:
00 Non-shareable.
10 Outer Shareable.
11 Inner Shareable.
The value 01 is reserved.

Note
This field returns the value 10 for:
• Any type of Device memory.
• Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

Bits [6:1]
Reserved, RES0.

F, bit [0]
When updating the PAR with the result of a translation operation, this bit indicates whether the conversion completed successfully.
0 The address translation operation completed successfully.
Hardware does not interpret this bit in any way, and therefore software can set this bit to 0 or 1 without affecting operation.
When PAR_EL1.F==1:

|   63 | 12 11 10 9 8 7 6 1 0   |
|      | RES0 S FST F PTW RES0 RES1 |

Bits [63:12]
- Reserved, RES0.

Bit [11]
- Reserved, RES1.

Bit [10]
- Reserved, RES0.

S, bit [9]
- Indicates the translation stage at which the translation aborted:
  0 Translation aborted because of a fault in the stage 1 translation.
  1 Translation aborted because of a fault in the stage 2 translation.

PTW, bit [8]
- If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

Bit [7]
- Reserved, RES0.

FST, bits [6:1]
- Fault status code, as shown in the Data Abort ESR encoding.

F, bit [0]
- When updating the PAR with the result of a translation operation, this bit indicates whether the conversion completed successfully:
  1 The address translation operation aborted.
- Hardware does not interpret this bit in any way, and therefore software can set this bit to 0 or 1 without affecting operation.

Accessing the PAR_EL1:

To access the PAR_EL1:

MRS <Xt>, PAR_EL1 ; Read PAR_EL1 into Xt
MSR PAR_EL1, <Xt> ; Write Xt to PAR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0111</td>
<td>0100</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.72 REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

**Purpose**

Provides implementation-specific minor revision information.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TID1==1, Non-secure EL1 read accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register REVIDR_EL1 is architecturally mapped to AArch32 System register `REVIDR`.

If REVIDR_EL1 has the same value as MIDR_EL1, then its contents have no significance.

**Attributes**

REVIDR_EL1 is a 32-bit register.

**Field descriptions**

The REVIDR_EL1 bit assignments are:

```
31 0
```

IMPLEMENTATION DEFINED

**Accessing the REVIDR_EL1:**

To access the REVIDR_EL1:

\[
\text{MRS } \langle Xt \rangle, \text{ REVIDR_EL1} ; \text{ Read REVIDR_EL1 into } X_t
\]

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.2.73  RMR_EL1, Reset Management Register (if EL2 and EL3 not implemented)

The RMR_EL1 characteristics are:

**Purpose**

If EL1 is the highest implemented Exception level:

- A write to the register can request a Warm reset.
- If EL1 can use AArch32 and AArch64, specifies the Execution state that the PE boots into on a Warm reset.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register RMR_EL1 is architecturally mapped to AArch32 System register RMR (at EL1).

Only implemented if EL1 is the highest implemented Exception level. In this case:

- If EL1 can use AArch32 and AArch64 then this register must be implemented.
- If EL1 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

RMR_EL1 is a 32-bit register.

**Field descriptions**

The RMR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RR</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AA64</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

Setting this bit to 1 requests a Warm reset.

This field resets to 0. This reset value applies on Warm and Cold resets.
AA64, bit [0]

When EL1 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

0  AArch32.
1  AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL1 cannot use AArch32 this bit is RAO/WI.

This field resets to 1. This reset value applies on Cold reset.

Accessing the RMR_EL1:

To access the RMR_EL1:

MRS <Xt>, RMR_EL1 ; Read RMR_EL1 into Xt
MSR RMR_EL1, <Xt> ; Write Xt to RMR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.74 RMR_EL2, Reset Management Register (if EL3 not implemented)

The RMR_EL2 characteristics are:

**Purpose**

If EL2 is the highest implemented Exception level:
- A write to the register can request a Warm reset.
- If EL2 can use AArch32 and AArch64, specifies the Execution state that the PE boots into on a Warm reset.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
<th>EL2 (NS)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register RMR_EL2 is architecturally mapped to AArch32 System register HRMR. Only implemented if EL2 is the highest implemented Exception level. In this case:
- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

RMR_EL2 is a 32-bit register.

**Field descriptions**

The RMR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RR</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

Setting this bit to 1 requests a Warm reset.

This field resets to 0. This reset value applies on Warm and Cold resets.
AA64, bit [0]

When EL2 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

0  AArch32.
1  AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch32 this bit is RAO/WI.

This field resets to 1. This reset value applies on Cold reset.

Accessing the RMR_EL2:

To access the RMR_EL2:

MRS <Xt>, RMR_EL2 ; Read RMR_EL2 into Xt
MSR RMR_EL2, <Xt> ; Write Xt to RMR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
### RMR_EL3, Reset Management Register (if EL3 implemented)

The RMR_EL3 characteristics are:

#### Purpose

If EL1 is the highest implemented Exception level:

- A write to the register can request a Warm reset.
- If EL2 can use AArch32 and AArch64, specifies the Execution state that the PE boots into on a Warm reset.

#### Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

#### Traps and Enables

There are no traps or enables affecting this register.

#### Configurations

AArch64 System register RMR_EL3 is architecturally mapped to AArch32 System register RMR (at EL3).

When EL3 is implemented:

- If EL3 can use AArch32 and AArch64 then this register must be implemented.
- If EL3 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

#### Attributes

RMR_EL3 is a 32-bit register.

#### Field descriptions

The RMR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

RES0

<table>
<thead>
<tr>
<th>RR</th>
</tr>
</thead>
</table>

AA64

#### Bits [31:2]

Reserved, RES0.

#### RR, bit [1]

Setting this bit to 1 requests a Warm reset.

This field resets to 0. This reset value applies on Warm and Cold resets.
AA64, bit [0]

When EL3 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

0      AArch32.
1      AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL3 cannot use AArch32 this bit is RAO/WI.

This field resets to 1. This reset value applies on Cold reset.

**Accessing the RMR_EL3:**

To access the RMR_EL3:

MRS <Xt>, RMR_EL3 ; Read RMR_EL3 into Xt
MSR RMR_EL3, <Xt> ; Write Xt to RMR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1100</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.76 RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)

The RVBAR_EL1 characteristics are:

Purpose
If EL1 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables
There are no traps or enables affecting this register.

Configurations
Only implemented if the highest Exception level implemented is EL1.

Attributes
RVBAR_EL1 is a 64-bit register.

Field descriptions
The RVBAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-0</td>
<td>Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits [1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.</td>
</tr>
</tbody>
</table>

Accessing the RVBAR_EL1:
To access the RVBAR_EL1:

MRS <Xt>, RVBAR_EL1 ; Read RVBAR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
### RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

**Purpose**

If EL2 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1</th>
<th>EL2 (NS)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>-</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

Only implemented if the highest Exception level implemented is EL2.

**Attributes**

RVBAR_EL2 is a 64-bit register.

**Field descriptions**

The RVBAR_EL2 bit assignments are:

```
63 0
```

**Bits [63:0]**

Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

**Accessing the RVBAR_EL2:**

To access the RVBAR_EL2:

MRS <Xt>, RVBAR_EL2 ; Read RVBAR_EL2 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.78 RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented)

The RVBAR_EL3 characteristics are:

**Purpose**

If EL3 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

Only implemented if the highest Exception level implemented is EL3.

**Attributes**

RVBAR_EL3 is a 64-bit register.

**Field descriptions**

The RVBAR_EL3 bit assignments are:

![RVBAR_EL3 bit assignments diagram]

**Accessing the RVBAR_EL3:**

To access the RVBAR_EL3:

MRS <Xt>, RVBAR_EL3 ; Read RVBAR_EL3 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.2.79  S3_<op1>_<_Cn>_<_Cm>_<_op2>, IMPLEMENTATION DEFINED registers

The S3_<op1>_<_Cn>_<_Cm>_<_op2> characteristics are:

**Purpose**

This area of the instruction set space is reserved for IMPLEMENTATION DEFINED registers.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMP DEF</td>
<td>IMP DEF</td>
<td>IMP DEF</td>
<td>IMP DEF</td>
<td>IMP DEF</td>
<td>IMP DEF</td>
</tr>
</tbody>
</table>

The numbers in these register names are encoded in decimal without leading zeroes, and the Cn and Cm fields require a literal C before the number. For example, S3_4_C11_C9_7.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If HCR_EL2.TIDCP==1, Non-secure EL1 accesses to this register are trapped to EL2.

**Configurations**

There are no configuration notes.

**Attributes**

S3_<op1>_<_Cn>_<_Cm>_<_op2> is a 32-bit register.

**Field descriptions**

The S3_<op1>_<_Cn>_<_Cm>_<_op2> bit assignments are:

```
| 31 | 0 |
|------------------------------|
| IMPLEMENTATION DEFINED |
```

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

**Accessing the S3_<op1>_<_Cn>_<_Cm>_<_op2>:**

To access the S3_<op1>_<_Cn>_<_Cm>_<_op2>:

MRS <Xt>, S3_<op1>_<_Cn>_<_Cm>_<_op2> ; Read S3_<op1>_<_Cn>_<_Cm>_<_op2> into Xt
MSR S3_<op1>_<_Cn>_<_Cm>_<_op2>, <Xt> ; Write Xt to S3_<op1>_<_Cn>_<_Cm>_<_op2>

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>xxx</td>
<td>1x11</td>
<td>xxxx</td>
<td>xxx</td>
</tr>
</tbody>
</table>
D7.2.80 SCR_EL3, Secure Configuration Register

The SCR_EL3 characteristics are:

**Purpose**

Defines the configuration of the current Security state. It specifies:

- The Security state of EL0 and EL1, either Secure or Non-secure.
- The Execution state at lower Exception levels.
- Whether IRQ, FIQ, and External Abort interrupts are taken to EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SCR_EL3 can be mapped to AArch32 System register SCR, but this is not architecturally mandated.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

SCR_EL3 is a 32-bit register.

**Field descriptions**

The SCR_EL3 bit assignments are:

![Field assignments diagram]

**Bits [31:14]**

Reserved, RES0.
### TWE, bit [13]

Traps EL2, EL1, and EL0 execution of WFE instructions to EL3, from both Security states and both Execution states.

0  EL2, EL1, and EL0 execution of WFE instructions is not trapped to EL3.
1  Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

### TWI, bit [12]

Traps EL2, EL1, and EL0 execution of WFI instructions to EL3, from both Security states and both Execution states.

0  EL2, EL1, and EL0 execution of WFI instructions is not trapped to EL3.
1  Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

### ST, bit [11]

Traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3, from AArch64 state only.

0  Secure EL1 using AArch64 accesses to the `CNTPS_TV_AL_EL1`, `CNTPS_CTL_EL1`, and `CNTPS_CVAL_EL1` are trapped to EL3.
1  Secure EL1 using AArch64 accesses to the `CNTPS_TV_AL_EL1`, `CNTPS_CTL_EL1`, and `CNTPS_CVAL_EL1` are not trapped to EL3.

### RW, bit [10]

Execution state control for lower Exception levels.

0  Lower levels are all AArch32.
1  The next lower level is AArch64.
   If EL2 is present:
   •  EL2 is AArch64.
   •  EL2 controls EL1 and EL0 behaviors.
   If EL2 is not present:
   •  EL1 is AArch64.
   •  EL0 is determined by the Execution state described in the current process state when executing at EL0.
If all lower exception levels cannot use AArch32 then this bit is RAO/WI.

This bit is permitted to be cached in a TLB.

**SIF, bit [9]**

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

0 Secure state instruction fetches from Non-secure memory are permitted.
1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

**HCE, bit [8]**

Hypervisor Call instruction enable. Enables HVC instructions at EL3, EL2, and Non-secure EL1, in both Execution states.

0 HVC instructions are UNDEFINED at EL3, EL2, and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
1 HVC instructions are enabled at EL1 and above.

--- **Note** ---

HVC instructions are always UNDEFINED at PL0.

---

If EL2 is not implemented, this bit is RES0.

**SMD, bit [7]**

Secure Monitor Call disable. Disables SMC instructions at EL1 and above, from both Security states and both Execution states.

0 SMC instructions are enabled at EL1 and above.
1 SMC instructions are UNDEFINED at EL1 and above.

--- **Note** ---

SMC instructions are always UNDEFINED at EL0.

---

**Bit [6]**

Reserved, RES0.

**Bits [5:4]**

Reserved, RES1.

**EA, bit [3]**

External Abort and SError Interrupt Routing.

0 When executing at Exception levels below EL3, External Aborts and SError Interrupts are not taken to EL3.

  In addition, when executing at EL3:

  • SError Interrupts are not taken.
  • External Aborts are taken to EL3.

1 When executing at any Exception level, External Aborts and SError Interrupts are taken to EL3.

For more information, see *Asynchronous exception routing on page D1-1553.*
FIQ, bit [2]

Physical FIQ Routing.
0  When executing at Exception levels below EL3, physical FIQ interrupts are not taken to EL3.
   When executing at EL3, physical FIQ interrupts are not taken.
1  When executing at any Exception level, physical FIQ interrupts are taken to EL3.
For more information, see Asynchronous exception routing on page D1-1553.

IRQ, bit [1]

Physical IRQ Routing.
0  When executing at Exception levels below EL3, physical IRQ interrupts are not taken to EL3.
   When executing at EL3, physical IRQ interrupts are not taken.
1  When executing at any Exception level, physical IRQ interrupts are taken to EL3.
For more information, see Asynchronous exception routing on page D1-1553.

NS, bit [0]

Non-secure bit.
0  Indicates that EL0 and EL1 are in Secure state, and so memory accesses from those Exception levels can access Secure memory.
1  Indicates that EL0 and EL1 are in Non-secure state, and so memory accesses from those Exception levels cannot access Secure memory.

Accessing the SCR_EL3:

To access the SCR_EL3:

MRS <Xt>, SCR_EL3 ; Read SCR_EL3 into Xt
MSR SCR_EL3, <Xt> ; Write Xt to SCR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0001</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.81  **SCTLR_EL1, System Control Register (EL1)**

The SCTLR_EL1 characteristics are:

**Purpose**

Provides top level control of the system, including its memory system, at EL1 and EL0.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register SCTLR_EL1 is architecturally mapped to AArch32 System register SCTLR.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL1 using AArch64. Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

SCTLR_EL1 is a 32-bit register.

**Field descriptions**

The SCTLR_EL1 bit assignments are:

![Field assignments diagram]

**Bits [31:30]**

Reserved, RES0.
Bits [29:28]
Reserved, RES1.

Bit [27]
Reserved, RES0.

UCI, bit [26]
Traps EL0 execution of cache maintenance instructions to EL1, from AArch64 state only.

0 Any attempt to execute a DC CVAU, DC CIVAC, DC CVAC, or IC IVAU instruction at EL0 using AArch64 is trapped to EL1.
1 EL0 execution of cache maintenance instructions is not trapped to EL1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

EE, bit [25]
Endianness of data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime.

The possible values of this bit are:

0 Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.
1 Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.
If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.
The EE bit is permitted to be cached in a TLB.
When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED value.

E0E, bit [24]
Endianness of data accesses at EL0.

The possible values of this bit are:

0 Explicit data accesses at EL0 are little-endian.
1 Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is RES0. This option is not permitted when SCTLR_EL1.EE is RES1.
If an implementation only supports Big-endian accesses at EL0 then this bit is RES1. This option is not permitted when SCTLR_EL1.EE is RES0.
This bit has no effect on the endianness of LDTR, LDTRH, LDTRSH, LDTRSW, STTR and STTRH instructions executed at EL1.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [23:22]
Reserved, RES1.

Bit [21]
Reserved, RES0.

Bit [20]
Reserved, RES1.
WXN, bit [19]
Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN for the EL1&0 translation regime. The possible values of this bit are:

- 0: Regions with write permission are not forced to XN.
- 1: Regions with write permission are forced to XN for the EL1&0 translation regime.

The WXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

nTWE, bit [18]
Traps EL0 execution of WFE instructions to EL1, from both Execution states.

- 0: Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.
- 1: EL0 execution of WFE instructions is not trapped to EL1.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [17]
Reserved, RES0.

nTWI, bit [16]
Traps EL0 execution of WFI instructions to EL1, from both Execution states.

- 0: Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.
- 1: EL0 execution of WFI instructions is not trapped to EL1.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

UCT, bit [15]
Traps EL0 accesses to the CTR_EL0 to EL1, from AArch64 state only.

- 0: Accesses to the CTR_EL0 from EL0 using AArch64 are trapped to EL1.
- 1: Accesses to the CTR_EL0 from EL0 using AArch64 are not trapped to EL1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
DZE, bit [14]
Traps EL0 execution of DC ZVA instructions to EL1, from AArch64 state only.
0 Any attempt to execute a DC ZVA instruction at EL0 using AArch64 is trapped to EL1. Reading DCZID_EL0.DZP from EL0 returns 1, indicating that DC ZVA instructions are not supported.
1 EL0 execution of DC ZVA instructions is not trapped to EL1.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [13]
Reserved, RES0.

I, bit [12]
Instruction access Cacheability control. This is an enable bit for instruction caches at EL0 and EL1:
0 All instruction access to Normal memory from EL0 and EL1 are Non-cacheable for all levels of instruction and unified cache.
   If the value of SCTLR_EL1.M is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
1 This control has no effect on the Cacheability of instruction access to Normal memory from EL0 and EL1.
   If the value of SCTLR_EL1.M is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.
When the value of the HCR_EL2.DC bit is 1, then instruction access to Normal memory from EL0 and EL1 are Cacheable regardless of the value of the SCTLR_EL1.I bit.
When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]
Reserved, RES1.

Bit [10]
Reserved, RES0.

UMA, bit [9]
User Mask Access. Traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1, from AArch64 state only.
0 Any attempt at EL0 using AArch64 to execute an MRS, MSR(register), or MSR(immediate) instruction that accesses the DAIF is trapped to EL1.
1 EL0 execution of MRS, MSR(register), or MSR(immediate) instructions that access the DAIF is not trapped to EL1.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SED, bit [8]
SETEND instruction disable. Disables SETEND instructions at EL0 using AArch32.
0 SETEND instruction execution is enabled at EL0 using AArch32.
1 SETEND instructions are UNDEFINED at EL0 using AArch32.
If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.
If EL0 cannot use AArch32, this bit is RES1.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
ITD, bit [7]

IT Disable. Disables some uses of IT instructions at EL0 using AArch32.

0  All IT instruction functionality is enabled at EL0 using AArch32.
1  Any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED:
   •  All encodings of the IT instruction with hw1[3:0]=1000.
   •  All encodings of the subsequent instruction with the following values for hw1:
      11xxxxxxxxxxxx
      ·  All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
      1011xxxxxxxxxx
      ·  All instructions in Miscellaneous 16-bit instructions on page F3-2536.
      1010xxxxxxxxxx
      ·  ADD Rd, PC, #imm
      01001xxxxxxxxx
      ·  LDR Rd, [PC, #imm]
      0100x1xx1111xxx
      ·  ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
      010001xx1xxxx111
      ·  ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block. It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:
   •  A 16-bit instruction, that can only be followed by another 16-bit instruction.
   •  The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If EL0 cannot use AArch32, this bit is RES1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

CP15 barrier operation instruction enable. Enables accesses to the CP15 DMB, DSB, and ISB barrier operations from EL0 using AArch32.

0  EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.
1  EL0 using AArch32: EL0 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

If EL0 cannot use AArch32, this bit is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
SA0, bit [4]
Stack Alignment Check Enable for EL0. When set, use of the stack pointer as the base address in a load/store instruction at EL0 must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SA, bit [3]
Stack Alignment Check Enable. When set, use of the stack pointer as the base address in a load/store instruction at EL1 must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

C, bit [2]
Cacheability control, for data caching.

0  All data access to Normal memory from EL0 and EL1, and Normal memory accesses to the EL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.

1  This control has no effect on the Cacheability of:
   • Data access to Normal memory from EL0 and EL1.
   • Normal memory accesses to the EL1&0 stage 1 translation tables.

When the value of the HCR_EL2.DC bit is 1, then data access to Normal memory from EL0 and EL1, and accesses to the EL1&0 stage 1 translation tables, can be cached regardless of the value of the SCTLR_EL1.C bit.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]
Alignment check enable. This is the enable bit for Alignment fault checking at EL1 and EL0:

0  Alignment fault checking disabled when executing at EL1 or EL0.
   Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1  Alignment fault checking enabled when executing at EL1 or EL0.
   All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

M, bit [0]
MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0  EL1 and EL0 stage 1 address translation disabled.
   See the SCTLR_EL1.I field for the behavior of instruction accesses to Normal memory.

1  EL1 and EL0 stage 1 address translation enabled.

If HCR_EL2.DC is set to 1, then in Non-secure state the SCTLR_EL1.M bit behaves as 0 for all purposes other than reading the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.
Accessing the SCTLR_EL1:

To access the SCTLR_EL1:

MRS <Xt>, SCTLR_EL1 ; Read SCTLR_EL1 into Xt
MSR SCTLR_EL1, <Xt> ; Write Xt to SCTLR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0001</td>

Bits [27:26]
Reserved, RES0.

EE, bit [25]
Endianness of data accesses at EL2, stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the EL1&0 translation regime.
The possible values of this bit are:
0 Explicit data accesses at EL2, stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the EL1&0 translation regime are little-endian.
1 Explicit data accesses at EL2, stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the EL1&0 translation regime are big-endian.
If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.
If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.
The EE bit is permitted to be cached in a TLB.
When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED value.

Bit [24]
Reserved, RES0.

Bits [23:22]
Reserved, RES1.

Bits [21:20]
Reserved, RES0.

WXN, bit [19]
Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN for the EL2 translation regime. The possible values of this bit are:
0 Regions with write permission are not forced to XN.
1 Regions with write permission are forced to XN for the EL2 translation regime.
The WXN bit is permitted to be cached in a TLB.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [17]
Reserved, RES0.

Bit [16]
Reserved, RES1.

Bits [15:13]
Reserved, RES0.
I, bit [12]

Instruction access Cacheability control, for accesses at EL2:

0    All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.

If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

1    This control has no effect on the Cacheability of instruction access to Normal memory from EL2.

If the value of SCTLR_EL2.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 or EL3 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

Stack Alignment Check Enable. When set, use of the stack pointer as the base address in a load/store instruction at EL2 must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

C, bit [2]

Cacheability control, for data caching.

0    All data access to Normal memory from EL2, and Normal memory accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.

1    This control has no effect on the Cacheability of:

• Data access to Normal memory from EL2.

• Normal memory accesses to the EL2 translation tables.

This bit has no effect on the EL1&0 or EL3 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

0    Alignment fault checking disabled when executing at EL2.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1    Alignment fault checking enabled when executing at EL2.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:
0       EL2 stage 1 address translation disabled.
         See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.
1       EL2 stage 1 address translation enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCTLR_EL2:

To access the SCTLR_EL2:

MRS <Xt>, SCTLR_EL2 ; Read SCTLR_EL2 into Xt
MSR SCTLR_EL2, <Xt> ; Write Xt to SCTLR_EL2

I, bit [12]

Instruction access Cacheability control, for accesses at EL3:
0. All instruction access to Normal memory from EL3 are Non-cacheable for all levels of instruction and unified cache.

If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
This control has no effect on the Cacheability of instruction access to Normal memory from EL3.

If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 or EL2 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

### Bit [11]

Reserved, RES1.

### Bits [10:6]

Reserved, RES0.

### Bits [5:4]

Reserved, RES1.

### SA, bit [3]

Stack Alignment Check Enable. When set, use of the stack pointer as the base address in a load/store instruction at EL3 must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

### C, bit [2]

Cacheability control, for data caching.

- 0 All data access to Normal memory from EL3, and Normal memory accesses to the EL3 translation tables, are Non-cacheable for all levels of data and unified cache.
- 1 This control has no effect on the Cacheability of:
  - Data access to Normal memory from EL3
  - Normal memory accesses to the EL3 translation tables.

This bit has no effect on the EL1&0 or EL2 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

### A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL3:

- 0 Alignment fault checking disabled when executing at EL3.
  Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
- 1 Alignment fault checking enabled when executing at EL3.
  All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

### M, bit [0]

MMU enable for EL3 stage 1 address translation. Possible values of this bit are:

- 0 EL3 stage 1 address translation disabled.

See the SCTLR_EL3.I field for the behavior of instruction accesses to Normal memory.
1 EL3 stage 1 address translation enabled.
When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the SCTLR_EL3:**

To access the SCTLR_EL3:

MRS <Xt>, SCTLR_EL3 ; Read SCTLR_EL3 into Xt
MSR SCTLR_EL3, <Xt> ; Write Xt to SCTLR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0001</td>
<td>000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.84 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

**Purpose**

Determines which of the Translation Table Base Registers defined the base address for a translation table walk required for the stage 1 translation of a memory access from EL0 or EL1. Also controls the translation table format and holds cacheability and shareability information.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the bits in TCR_EL1 are permitted to be cached in a TLB.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register TCR_EL1[31:0] is architecturally mapped to AArch32 System register TTBCR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

TCR_EL1 is a 64-bit register.

**Field descriptions**

The TCR_EL1 bit assignments are:

| 63 | 39 | 38 | 37 | 36 | 35 | 34 | 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | IPS | TG1 | SH1 | T1SZ | TG0 | SH0 | T0SZ | RES0 | EPD0 | IRGN0 | ORGN0 | A1 | EPD1 |
| TBI1 | TBI0 | AS | RES0 | ORGN1 | IRGN1 |

**Bits [63:39]**

Reserved, RES0.

**TBI1, bit [38]**

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR1_EL1 region, or ignored and used for tagged addresses.

0 Top Byte used in the address calculation.
Top Byte ignored in the address calculation.
This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI1 is 1 and bit [55] of the target address is 1, caused by:
- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

In these cases bits [63:56] of the address are also set to 1 before it is stored in the PC.

TB10, bit [37]
Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL1 region, or ignored and used for tagged addresses.
0 Top Byte used in the address calculation.
1 Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TB10 is 1 and bit [55] of the target address is 0, caused by:
- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

In these cases bits [63:56] of the address are also set to 0 before it is stored in the PC.

AS, bit [36]
ASID Size.
0 8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.
1 16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

Bit [35]
Reserved, RES0.

IPS, bits [34:32]
Intermediate Physical Address Size.
000 32 bits, 4GB.
001 36 bits, 64GB.
010 40 bits, 1TB.
011 42 bits, 4TB.
100 44 bits, 16TB.
101 48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.
TG1, bits [31:30]

TTBR1_EL1 Granule size.
01  16KB
10  4KB
11  64KB

Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then
the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED
choice of the sizes that has been implemented for all purposes other than the value read back from
this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value
that corresponds to the size chosen.

SH1, bits [29:28]
Shareability attribute for memory associated with translation table walks using TTBR1_EL1.
00  Non-shareable
10  Outer Shareable
11  Inner Shareable

Other values are reserved.

ORGN1, bits [27:26]
Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL1.
00  Normal memory, Outer Non-cacheable
01  Normal memory, Outer Write-Back Write-Allocate Cacheable
10  Normal memory, Outer Write-Through Cacheable
11  Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN1, bits [25:24]
Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL1.
00  Normal memory, Inner Non-cacheable
01  Normal memory, Inner Write-Back Write-Allocate Cacheable
10  Normal memory, Inner Write-Through Cacheable
11  Normal memory, Inner Write-Back no Write-Allocate Cacheable

EPD1, bit [23]
Translation table walk disable for translations using TTBR1_EL1. This bit controls whether a
translation table walk is performed on a TLB miss, for an address that is translated using
TTBR1_EL1. The encoding of this bit is:
0  Perform translation table walks using TTBR1_EL1.
1  A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation
fault. No translation table walk is performed.

A1, bit [22]
Selects whether TTBR0_EL1 or TTBR1_EL1 defines the ASID. The encoding of this bit is:
0  TTBR0_EL1.ASID defines the ASID.
1  TTBR1_EL1.ASID defines the ASID.

T1SZ, bits [21:16]
The size offset of the memory region addressed by TTBR1_EL1. The region size is $2^{(64-T1SZ)}$ bytes.
The maximum and minimum possible values for \( T1SZ \) depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

**TG0, bits [15:14]**
Granule size for the corresponding translation table base address register.
- 00: 4KB
- 01: 64KB
- 10: 16KB
Other values are reserved.
If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.
It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

**SH0, bits [13:12]**
Shareability attribute for memory associated with translation table walks using \( TTBR0\_EL1 \).
- 00: Non-shareable
- 10: Outer Shareable
- 11: Inner Shareable
Other values are reserved.

**ORGN0, bits [11:10]**
Outer cacheability attribute for memory associated with translation table walks using \( TTBR0\_EL1 \).
- 00: Normal memory, Outer Non-cacheable
- 01: Normal memory, Outer Write-Back Write-Allocate Cacheable
- 10: Normal memory, Outer Write-Through Cacheable
- 11: Normal memory, Outer Write-Back no Write-Allocate Cacheable

**IRGN0, bits [9:8]**
Inner cacheability attribute for memory associated with translation table walks using \( TTBR0\_EL1 \).
- 00: Normal memory, Inner Non-cacheable
- 01: Normal memory, Inner Write-Back Write-Allocate Cacheable
- 10: Normal memory, Inner Write-Through Cacheable
- 11: Normal memory, Inner Write-Back no Write-Allocate Cacheable

**EPD0, bit [7]**
Translation table walk disable for translations using \( TTBR0 \). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using \( TTBR0 \). The encoding of this bit is:
- 0: Perform translation table walks using \( TTBR0 \).
- 1: A TLB miss on an address that is translated using \( TTBR0 \) generates a Translation fault. No translation table walk is performed.

**Bit [6]**
Reserved, RES0.

**T0SZ, bits [5:0]**
The size offset of the memory region addressed by \( TTBR0\_EL1 \). The region size is \( 2^{(64-T0SZ)} \) bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

**Accessing the TCR_EL1:**

To access the TCR_EL1:

MRS <Xt>, TCR_EL1 ; Read TCR_EL1 into Xt
MSR TCR_EL1, <Xt> ; Write Xt to TCR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0010</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
**D7.2.85 TCR_EL2, Translation Control Register (EL2)**

The TCR_EL2 characteristics are:

**Purpose**

Controls translation table walks required for the stage 1 translation of memory accesses from EL2, and holds cacheability and shareability information for the accesses.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>El0</th>
<th>El1 (NS)</th>
<th>El1 (S)</th>
<th>El2 (NS)</th>
<th>El3 (SCR.NS=1)</th>
<th>El3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register TCR_EL2 is architecturally mapped to AArch32 System register **HTCR**.

If EL2 is not implemented, this register is **RES0** from EL3.

RW fields in this register reset to **IMPLEMENTATION DEFINED** values that might be **UNKNOWN**.

**Attributes**

TCR_EL2 is a 32-bit register.

**Field descriptions**

The TCR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>31 30</th>
<th>24 23 22 21 20 19 18</th>
<th>16 15 14 13 12 11 10 9 8 7 6 5 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PS TG0 SH0 T0SZ</td>
<td>RES0 IRGN0 ORGN0</td>
</tr>
<tr>
<td>RES1</td>
<td>RES1</td>
<td>RES0</td>
</tr>
<tr>
<td>RES1</td>
<td>TBI</td>
<td>RES0</td>
</tr>
<tr>
<td>RES0</td>
<td>TBI</td>
<td>RES0</td>
</tr>
<tr>
<td>RES0</td>
<td>RES0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bit [31]**

Reserved, **RES1**.

**Bits [30:24]**

Reserved, **RES0**.

**Bit [23]**

Reserved, **RES1**.

**Bits [22:21]**

Reserved, **RES0**.
TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

0  Top Byte used in the address calculation.
1  Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2 translation regime is enabled or not.

Additionally, this affects to the program counter, when TBI is 1, caused by:

• A branch or procedure return within EL2.
• An exception taken to EL2.
• An exception return to EL2.

In these cases bits [63:56] of the address are set to 0 before it is stored in the PC.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

000  32 bits, 4GB.
001  36 bits, 64GB.
010  40 bits, 1TB.
011  42 bits, 4TB.
100  44 bits, 16TB.
101  48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the corresponding translation table base address register.

0  4KB
1  64KB
10  16KB

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL2.

0  Non-shareable
10  Outer Shareable
11  Inner Shareable

Other values are reserved.
ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

00  Normal memory, Outer Non-cacheable
01  Normal memory, Outer Write-Back Write-Allocate Cacheable
10  Normal memory, Outer Write-Through Cacheable
11  Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

00  Normal memory, Inner Non-cacheable
01  Normal memory, Inner Write-Back Write-Allocate Cacheable
10  Normal memory, Inner Write-Through Cacheable
11  Normal memory, Inner Write-Back no Write-Allocate Cacheable

Bits [7:6]
Reserved, RES0.

T0SZ, bits [5:0]
The size offset of the memory region addressed by TTBR0_EL2. The region size is $2^{(64-T0SZ)}$ bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and
the memory translation granule size, as described in the AArch64 Virtual Memory System
Architecture chapter.

Accessing the TCR_EL2:

To access the TCR_EL2:

MRS <Xt>, TCR_EL2 ; Read TCR_EL2 into Xt
MSR TCR_EL2, <Xt> ; Write Xt to TCR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0010</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.86  TCR_EL3, Translation Control Register (EL3)

The TCR_EL3 characteristics are:

**Purpose**

Controls translation table walks required for the stage 1 translation of memory accesses from EL3, and holds cacheability and shareability information for the accesses.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the bits in TCR_EL3 are permitted to be cached in a TLB.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

TCR_EL3 is a 32-bit register.

**Field descriptions**

The TCR_EL3 bit assignments are:

```
31 30 24 23 22 21 20 19 18 16 15 14 13 12 11 10 9 8 7 6 5 0

<td></td>
</tr>
</tbody>
</table>
```

**Bit [31]**

Reserved, RES1.

**Bits [30:24]**

Reserved, RES0.

**Bit [23]**

Reserved, RES1.

**Bits [22:21]**

Reserved, RES0.
TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL3 region, or ignored and used for tagged addresses.

0  Top Byte used in the address calculation.
1  Top Byte ignored in the address calculation.

This affects addresses generated in EL3 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL3. It has an effect whether the EL3 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI is 1, caused by:

• A branch or procedure return within EL3.
• A exception taken to EL3.
• An exception return to EL3.

In these cases bits [63:56] of the address are set to 0 before it is stored in the PC.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

000  32 bits, 4GB.
001  36 bits, 64GB.
010  40 bits, 1TB.
011  42 bits, 4TB.
100  44 bits, 16TB.
101  48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the corresponding translation table base address register.

0  4KB
1  64KB
10  16KB

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL3.

0  Non-shareable
10  Outer Shareable
11  Inner Shareable

Other values are reserved.
**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using TTRB0_EL3.

- 00  Normal memory, Outer Non-cacheable
- 01  Normal memory, Outer Write-Back Write-Allocate Cacheable
- 10  Normal memory, Outer Write-Through Cacheable
- 11  Normal memory, Outer Write-Back no Write-Allocate Cacheable

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using TTRB0_EL3.

- 00  Normal memory, Inner Non-cacheable
- 01  Normal memory, Inner Write-Back Write-Allocate Cacheable
- 10  Normal memory, Inner Write-Through Cacheable
- 11  Normal memory, Inner Write-Back no Write-Allocate Cacheable

**Bits [7:6]**

Reserved, RES0.

**T0SZ, bits [5:0]**

The size offset of the memory region addressed by TTRB0_EL3. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

### Accessing the TCR_EL3:

To access the TCR_EL3:

```assembly
MRS <Xt>, TCR_EL3 ; Read TCR_EL3 into Xt
MSR TCR_EL3, <Xt> ; Write Xt to TCR_EL3
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>

</tbody>
</table>

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TPIDRRO_EL0[31:0] is architecturally mapped to AArch32 System register TPIDRRO.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

TPIDRRO_EL0 is a 64-bit register.

Field descriptions

The TPIDRRO_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread ID</td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRRO_EL0:

To access the TPIDRRO_EL0:

MRS <Xt>, TPIDRRO_EL0 ; Read TPIDRRO_EL0 into Xt
MSR TPIDRRO_EL0, <Xt> ; Write Xt to TPIDRRO_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1101</td>
<td>0000</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.2.92  TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

**Purpose**

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses at EL0 and EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

**Configurations**

AArch64 System register TTBR0_EL1 is architecturally mapped to AArch32 System register TTBR0.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

TTBR0_EL1 is a 64-bit register.

**Field descriptions**

The TTBR0_EL1 bit assignments are:

- **ASID**, bits [63:48]
  
  An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.
  
  If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

- **BADDR**, bits [47:0]
  
  Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be on of the following:
  
  - Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
  - The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.
The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T0SZ, the stage of translation, and the translation granule size.

**Accessing the TTBR0_EL1:**

To access the TTBR0_EL1:

- MRS <Xt>, TTBR0_EL1; Read TTBR0_EL1 into Xt
- MSR TTBR0_EL1, <Xt>; Write Xt to TTBR0_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0010</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.93   TTBR0_EL2, Translation Table Base Register 0 (EL2)

The TTBR0_EL2 characteristics are:

**Purpose**

Holds the base address of the translation table for the stage 1 translation of memory accesses from EL2.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register TTBR0_EL2 is architecturally mapped to AArch32 System register HTTBR.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

TTBR0_EL2 is a 64-bit register.

**Field descriptions**

The TTBR0_EL2 bit assignments are:

```
  63  48  47  0
      RES0  BADDR
```

**Bits [63:48]**

Reserved, RES0.

**BADDR, bits [47:0]**

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL2.T0SZ, the stage of translation, and the translation granule size.

**Accessing the TTBR0_EL2:**

To access the TTBR0_EL2:
MRS <Xt>, TTBR0_EL2 ; Read TTBR0_EL2 into Xt
MSR TTBR0_EL2, <Xt> ; Write Xt to TTBR0_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0010</td>
<td>0000</td>
<td>00</td>
</tr>
</tbody>
</table>
D7.2.94 TTBR0_EL3, Translation Table Base Register 0 (EL3)

The TTBR0_EL3 characteristics are:

**Purpose**
Holds the base address of the translation table for the stage 1 translation of memory accesses from EL3.

**Usage constraints**
This register is accessible as follows:

Any of the fields in this register are permitted to be cached in a TLB.

**Traps and Enables**
There are no traps or enables affecting this register.

**Configurations**
RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**
TTBR0_EL3 is a 64-bit register.

**Field descriptions**
The TTBR0_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

**Details**

**BADDR**, bits [47:0]
Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRANDED UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL3.T0SZ, the stage of translation, and the translation granule size.

**Accessing the TTBR0_EL3:**

To access the TTBR0_EL3:

MRS <Xt>, TTBR0_EL3 ; Read TTBR0_EL3 into Xt
MSR TTBR0_EL3, <Xt> ; Write Xt to TTBR0_EL3
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0010</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.2.95   TTBR1_EL1, Translation Table Base Register 1

The TTBR1_EL1 characteristics are:

Purpose

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses at EL0 and EL1.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the fields in this register are permitted to be cached in a TLB.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If HCR_EL2.TRVM==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If HCR_EL2.TVM==1, Non-secure EL1 write accesses to this register are trapped to EL2.

Configurations

AArch64 System register TTBR1_EL1 is architecturally mapped to AArch32 System register TTBR1.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

TTBR1_EL1 is a 64-bit register.

Field descriptions

The TTBR1_EL1 bit assignments are:

![TTBR1_EL1 bit assignments diagram]

ASID, bits [63:48]

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.
The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T1SZ, the stage of translation, and the translation granule size.

**Accessing the TTBR1_EL1:**

To access the TTBR1_EL1:

MRS <Xt>, TTBR1_EL1 ; Read TTBR1_EL1 into Xt
MSR TTBR1_EL1, <Xt> ; Write Xt to TTBR1_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>

<td>001</td>
</tr>
</tbody>
</table>
D7.2.96 VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

**Purpose**

Holds the vector base address for any exception that is taken to EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register VBAR_EL1[31:0] is architecturally mapped to AArch32 System register VBAR.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

VBAR_EL1 is a 64-bit register.

**Field descriptions**

The VBAR_EL1 bit assignments are:

![Vector Base Address Diagram]

**Bits [63:11]**

Vector Base Address. Base address of the exception vectors for exceptions taken to EL1.

If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

**Bits [10:0]**

Reserved, RES0.

**Accessing the VBAR_EL1:**

To access the VBAR_EL1:

MRS <Xt>, VBAR_EL1 ; Read VBAR_EL1 into Xt
MSR VBAR_EL1, <Xt> ; Write Xt to VBAR_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>

</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register VMPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VMPIDR.

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MPIDR_EL1.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

VMPIDR_EL2 is a 64-bit register.

**Field descriptions**

The VMPIDR_EL2 bit assignments are:

```
0 7 8 15 16 24 25 29 30 31 32 39 40 63
RES1 U RES0 Aff0 Aff1 Aff2 RES0 Aff3
RES0
```

**Bits [63:40]**

Reserved, RES0.

**Aff3, bits [39:32]**

Affinity level 3. Highest level affinity field.

**Bit [31]**

Reserved, RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0: Processor is part of a multiprocessor system.
- 1: Processor is part of a uniprocessor system.

**Bits [29:25]**

Reserved, RES0.
MT, bit [24]
Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. The possible values of this bit are:

0 Performance of PEs at the lowest affinity level is largely independent.
1 Performance of PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]
Affinity level 2. Second highest level affinity field.

Aff1, bits [15:8]
Affinity level 1. Third highest level affinity field.

Aff0, bits [7:0]
Affinity level 0. Lowest level affinity field.

Accessing the VMPIDR_EL2:
To access the VMPIDR_EL2:

MRS <Xt>, VMPIDR_EL2 ; Read VMPIDR_EL2 into Xt
MSR VMPIDR_EL2, <Xt> ; Write Xt to VMPIDR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0000</td>
<td>0000</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.2.100 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

**Purpose**

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR_EL1.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register VPIDR_EL2 is architecturally mapped to AArch32 System register VPIDR.

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MIDR_EL1.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

VPIDR_EL2 is a 32-bit register.

**Field descriptions**

The VPIDR_EL2 bit assignments are:

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x40</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
</tbody>
</table>
ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

**Architecture, bits [19:16]**

The permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>ARMv4</td>
</tr>
<tr>
<td>0010</td>
<td>ARMv4T</td>
</tr>
<tr>
<td>0011</td>
<td>ARMv5 (obsolete)</td>
</tr>
<tr>
<td>0100</td>
<td>ARMv5T</td>
</tr>
<tr>
<td>0101</td>
<td>ARMv5TE</td>
</tr>
<tr>
<td>0110</td>
<td>ARMv5TEJ</td>
</tr>
<tr>
<td>0111</td>
<td>ARMv6</td>
</tr>
<tr>
<td>1111</td>
<td>Architectural features are individually identified in the ID_ * registers, see Identification registers, functional group on page G4-4232.</td>
</tr>
</tbody>
</table>

All other values are reserved.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

### Accessing the VPIDR_EL2:

To access the VPIDR_EL2:

- **MRS <Xt>, VPIDR_EL2** ; Read VPIDR_EL2 into Xt
- **MSR VPIDR_EL2, <Xt>** ; Write Xt to VPIDR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
### D7.2.101 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

#### Purpose

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure EL0 and EL1, and holds cacheability and shareability information for the accesses.

#### Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

#### Traps and Enables

There are no traps or enables affecting this register.

#### Configurations

AArch64 System register VTCR_EL2 is architecturally mapped to AArch32 System register VTCR.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

#### Attributes

VTCR_EL2 is a 32-bit register.

#### Field descriptions

The VTCR_EL2 bit assignments are:

```
  31 30  19  18  16  15  14  13  12  11  10  9   8   7   6   5   4   3   2   1   0

<table>
<thead>
<tr>
<th>RES0</th>
<th>PS</th>
<th>TG0</th>
<th>SH0</th>
<th>SL0</th>
<th>T0SZ</th>
</tr>
</thead>
</table>
```

#### Bit [31]

Reserved, RES1.

#### Bits [30:19]

Reserved, RES0.

#### PS, bits [18:16]

Physical Address Size.

- 000: 32 bits, 4GB.
- 001: 36 bits, 64GB.
- 010: 40 bits, 1TB.
- 011: 42 bits, 4TB.
- 100: 44 bits, 16TB.
101  48 bits, 256TB.
    Other values are reserved.
    The reserved values behave in the same way as the 101 encoding, but software must not rely on this
    property as the behavior of the RESERVED values might change in a future revision of the
    architecture.

TG0, bits [15:14]
    Granule size for the corresponding translation table base address register.
    00  4KB
    01  64KB
    10  16KB
    Other values are reserved.
    If the value is programmed to either a reserved value, or a size that has not been implemented, then
    the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED
    choice of the sizes that has been implemented for all purposes other than the value read back from
    this register.
    It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value
    that corresponds to the size chosen.

SH0, bits [13:12]
    Shareability attribute for memory associated with translation table walks using VTTBR_EL2.
    00  Non-shareable
    10  Outer Shareable
    11  Inner Shareable
    Other values are reserved.

ORGN0, bits [11:10]
    Outer cacheability attribute for memory associated with translation table walks using VTTBR_EL2.
    00  Normal memory, Outer Non-cacheable
    01  Normal memory, Outer Write-Back Write-Allocate Cacheable
    10  Normal memory, Outer Write-Through Cacheable
    11  Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]
    Inner cacheability attribute for memory associated with translation table walks using VTTBR_EL2.
    00  Normal memory, Inner Non-cacheable
    01  Normal memory, Inner Write-Back Write-Allocate Cacheable
    10  Normal memory, Inner Write-Through Cacheable
    11  Normal memory, Inner Write-Back no Write-Allocate Cacheable

SL0, bits [7:6]
    Starting level of the VTCR_EL2 addressed region. The meaning of this field depends on the value
    of VTCR_EL2.TG0 (the granule size).
    00  If TG0 is 00 (4KB granule), start at level 2. If TG0 is 10 (16KB granule) or 01 (64KB
        granule), start at level 3.
    01  If TG0 is 00 (4KB granule), start at level 1. If TG0 is 10 (16KB granule) or 01 (64KB
        granule), start at level 2.
    10  If TG0 is 00 (4KB granule), start at level 0. If TG0 is 10 (16KB granule) or 01 (64KB
        granule), start at level 1.
    Other values are reserved.
T0SZ, bits [5:0]

The size offset of the memory region addressed by VTTBR_EL2. The region size is $2^{(64-T0SZ)}$ bytes.
The maximum and minimum possible values for T0SZ depend on the level of translation table and
the memory translation granule size, as described in the AArch64 Virtual Memory System
Architecture chapter.

Accessing the VTCR_EL2:

To access the VTCR_EL2:

MRS <Xt>, VTCR_EL2 ; Read VTCR_EL2 into Xt
MSR VTCR_EL2, <Xt> ; Write Xt to VTCR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0010</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.2.102 VTTBR_EL2, Virtualization Translation Table Base Register

The VTTBR_EL2 characteristics are:

**Purpose**

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure EL0 and EL1.

**Usage constraints**

This register is accessible as follows:

```
+---+---+---+---+---+---+
| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
+---+---+---+---+---+---+
  -   -   -   RW   RW   RW
```

Any of the fields in this register are permitted to be cached in a TLB.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register VTTBR_EL2 is architecturally mapped to AArch32 System register VTTBR.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

VTTBR_EL2 is a 64-bit register.

**Field descriptions**

The VTTBR_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:56</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>55:48</td>
<td>VMID, bits [55:48]</td>
</tr>
<tr>
<td>47:0</td>
<td>BADDR, bits [47:0]</td>
</tr>
</tbody>
</table>

VMID, bits [55:48]

The VMID for the translation table.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of VTCR_EL2.T0SZ, the stage of translation, and the translation granule size.
Accessing the VTTBR_EL2:

To access the VTTBR_EL2:

MRS <Xt>, VTTBR_EL2 ; Read VTTBR_EL2 into Xt
MSR VTTBR_EL2, <Xt> ; Write Xt to VTTBR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0010</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3 Debug registers

This section lists the Debug registers in AArch64.
D7.3.1  DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 read accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 System register DBGAUTHSTATUS.

AArch64 System register DBGAUTHSTATUS_EL1 is architecturally mapped to External register DBGAUTHSTATUS_EL1.

**Attributes**

DBGAUTHSTATUS_EL1 is a 32-bit register.

**Field descriptions**

The DBGAUTHSTATUS_EL1 bit assignments are:

```
   Bits [31:8]  31  8  7  6  5  4  3  2  1  0

   RES0          |
   | SNI  | SID | NSID |

   NSNID
```

- **Bits [31:8]**
  
  Reserved, RES0.

- **SNID, bits [7:6]**
  
  Secure non-invasive debug. Possible values of this field are:
  
  - 00: Not implemented. EL3 is not implemented and the implemented Security state is Non-Secure state.
  - 10: Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
  - 11: Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

  Other values are reserved.
SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

- **00**: Not implemented. EL3 is not implemented and the implemented Security state is Non-Secure state.
- **10**: Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- **11**: Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

- **00**: Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
- **10**: Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- **11**: Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

- **00**: Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
- **10**: Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
- **11**: Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

**Accessing the DBGAUTHSTATUS_EL1:**

To access the DBGAUTHSTATUS_EL1:

```
MRS <Xt>, DBGAUTHSTATUS_EL1 ; Read DBGAUTHSTATUS_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0111</td>
<td>110</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.3.2  DBGBCR\(<n>\)_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR\(<n>\)_EL1 characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint \(n\) together with value register DBGBVR\(<n>\)_EL1, where \(n\) is 0 to 15.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546 and *Software Access debug event* on page H3-5037. Subject to the prioritization rules:

- If EDSCR.TDA==1, and OSLSR.OSLK==0, EL1, EL2, and EL3 accesses to this register are trapped to Debug state.
- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register DBGBCR\(<n>\)_EL1 is architecturally mapped to AArch32 System register DBGBCR\(<n>\).

AArch64 System register DBGBCR\(<n>\)_EL1 is architecturally mapped to External register DBGBCR\(<n>\)_EL1.

**Attributes**

DBGBCR\(<n>\)_EL1 is a 32-bit register.

**Field descriptions**

The DBGBCR\(<n>\)_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15 14 12</th>
<th>9 8</th>
<th>5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>BT</td>
<td>LBN</td>
<td>SSC</td>
<td>RES0</td>
<td>BAS</td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**BT, bits [23:20]**

Breakpoint Type. Possible values are:

- 0000  Unlinked address match.
- 0001  Linked address match.
0010  Unlinked context ID match.
0011  Linked context ID match
0100  Unlinked address mismatch.
0101  Linked address mismatch.
1000  Unlinked VMID match.
1001  Linked VMID match.
1010  Unlinked VMID and context ID match.
1011  Linked VMID and context ID match.

The field breaks down as follows:
• BT[3:1]: Base type.
  000  Match address. DBGBVR<n>_EL1 is the address of an instruction.
  010  Mismatch address. Behaves as type 000 if in an AArch64 translation, or if Halting debug is enabled and halting is allowed. Otherwise, DBGBVR<n>_EL1 is the address of an instruction to be stepped.
  001  Match context ID. DBGBVR<n>_EL1[31:0] is a context ID.
  100  Match VMID. DBGBVR<n>_EL1[39:32] is a VMID.
  101  Match VMID and context ID. DBGBVR<n>_EL1[31:0] is a context ID, and DBGBVR<n>_EL1[39:32] is a VMID.
• BT[0]: Enable linking.
  If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

LBN, bits [19:16]
Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

SSC, bits [15:14]
Security state control. Determines the Security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

HMC, bit [13]
Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.
豉 [12:9]

Reserved, RES0.

豉, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

• BAS[2] and BAS[0] are read/write.
• BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0011 and 1100 are only supported if AArch32 is supported at any Exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0011</td>
<td>DBGVR&lt;n&gt;_EL1</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>1100</td>
<td>DBGVR&lt;n&gt;_EL1+2</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>1111</td>
<td>DBGVR&lt;n&gt;_EL1</td>
<td>Use for A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Step instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint.</td>
</tr>
<tr>
<td>0011</td>
<td>DBGVR&lt;n&gt;_EL1</td>
<td>Use for stepping T32 instructions.</td>
</tr>
<tr>
<td>1100</td>
<td>DBGVR&lt;n&gt;_EL1+2</td>
<td>Use for stepping T32 instructions.</td>
</tr>
<tr>
<td>1111</td>
<td>DBGVR&lt;n&gt;_EL1</td>
<td>Use for stepping A32 instructions.</td>
</tr>
</tbody>
</table>

For Context matching breakpoints, this field is RES1 and ignored.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

豉 [4:3]

Reserved, RES0.

豉, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

E, bit [0]

Enable break DBGBVR<n>_EL1. Possible values are:

0 Breakpoint disabled.
1 Breakpoint enabled.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

**Accessing the DBGBCR\(n\)\_EL1:**

To access the DBGBCR\(n\)\_EL1:

\[
\text{MRS} \ <Xt>, \ \text{DBGBCR}\(n\)\_EL1 \ ; \ \text{Read} \ \text{DBGBCR}\(n\)\_EL1 \ \text{into} \ <Xt>, \ \text{where} \ n \ \text{is in the range} \ 0 \ \text{to} \ 15 \\
\text{MSR} \ \text{DBGBCR}\(n\)\_EL1, \ <Xt> \ ; \ \text{Write} \ <Xt> \ \text{to} \ \text{DBGBCR}\(n\)\_EL1, \ \text{where} \ n \ \text{is in the range} \ 0 \ \text{to} \ 15
\]

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>(n^{3:0})</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.3.3 **DBGBVR<\(n\)>_EL1, Debug Breakpoint Value Registers, \(n = 0 - 15\)**

The DBGBVR<\(n\)>_EL1 characteristics are:

**Purpose**

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint \(n\) together with control register DBGBCR<\(n\)>_EL1, where \(n\) is 0 to 15.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546* and *Software Access debug event on page H3-5037*. Subject to the prioritization rules:

- If EDSCR.TDA==1, and OSLSR.OSLK==0, EL1, EL2, and EL3 accesses to this register are trapped to Debug state.
- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

- AArch64 System register DBGBVR<\(n\)>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR<\(n\)>.
- AArch64 System register DBGBVR<\(n\)>_EL1[63:32] is architecturally mapped to AArch32 System register DBGBUXVR<\(n\)>.
- AArch64 System register DBGBVR<\(n\)>_EL1 is architecturally mapped to External register DBGBVR<\(n\)>_EL1.

**Attributes**

DBGBVR<\(n\)>_EL1 is a 64-bit register.

**Field descriptions**

The DBGBVR<\(n\)>_EL1 bit assignments are:

*When DBGBCR<\(n\)>_EL1.BT==0b0x0x:*

<table>
<thead>
<tr>
<th>63</th>
<th>49</th>
<th>48</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES3</td>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**RESS, bits [63:49]**

Reserved. Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

**VA, bits [48:2]**

Bits[48:2] of the address value for comparison.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally **UNKNOWN**.
This field resets to its defined reset value on Cold reset.

**Bits [1:0]**

Reserved, **RES0**.

* **When DBGBCR<\texttt{n}>_EL1.BT==0b0\texttt{1x}:**

<table>
<thead>
<tr>
<th>63</th>
<th>32-31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ContextID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, **RES0**.

**ContextID, bits [31:0]**

Context ID value for comparison.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally **UNKNOWN**.
This field resets to its defined reset value on Cold reset.

* **When DBGBCR<\texttt{n}>_EL1.BT==0b1\texttt{x0x} and EL2 implemented:**

<table>
<thead>
<tr>
<th>63</th>
<th>40-39</th>
<th>32-31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID</td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:40]**

Reserved, **RES0**.

**VMID, bits [39:32]**

VMID value for comparison.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally **UNKNOWN**.
This field resets to its defined reset value on Cold reset.

**Bits [31:0]**

Reserved, **RES0**.

* **When DBGBCR<\texttt{n}>_EL1.BT==0x1\texttt{1x} and EL2 implemented:**

<table>
<thead>
<tr>
<th>63</th>
<th>40-39</th>
<th>32-31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID</td>
<td>ContextID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:40]**

Reserved, **RES0**.
VMID, bits [39:32]

VMID value for comparison.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Cold reset.

ContextID, bits [31:0]

Context ID value for comparison.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Cold reset.

**Accessing the DBGBVR<n>_EL1:**

To access the DBGBVR<n>_EL1:

MRS <Xt>, DBGBVR<n>_EL1 ; Read DBGBVR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGBVR<n>_EL1, <Xt> ; Write Xt to DBGBVR<n>_EL1, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>n&lt;3:0&gt;</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.3.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

**Purpose**

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 System register DBGCLAIMCLR.

AArch64 System register DBGCLAIMCLR_EL1 is architecturally mapped to External register DBGCLAIMCLR_EL1.

**Attributes**

DBGCLAIMCLR_EL1 is a 32-bit register.

**Field descriptions**

The DBGCLAIMCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td></td>
<td>CLAIM</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Cold reset.

**Accessing the DBGCLAIMCLR_EL1:**

To access the DBGCLAIMCLR_EL1:
MRS <Xt>, DBGCLAIMCLR_EL1 ; Read DBGCLAIMCLR_EL1 into Xt
MSR DBGCLAIMCLR_EL1, <Xt> ; Write Xt to DBGCLAIMCLR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0111</td>
<td>1001</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.3.5  DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register DBGCLAIMSET_EL1 is architecturally mapped to AArch32 System register DBGCLAIMSET.

AArch64 System register DBGCLAIMSET_EL1 is architecturally mapped to External register DBGCLAIMSET_EL1.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/SBZ</td>
<td>CLAIM</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim set bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.

A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Cold reset.

Accessing the DBGCLAIMSET_EL1:

To access the DBGCLAIMSET_EL1:
MRS <Xt>, DBGCLAIMSET_EL1 ; Read DBGCLAIMSET_EL1 into Xt
MSR DBGCLAIMSET_EL1, <Xt> ; Write Xt to DBGCLAIMSET_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0111</td>
<td>1000</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.3.6  DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

**Purpose**

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If MDSCR_EL1.TDCC==1, EL0 accesses to this register are trapped to EL1.

**Configurations**

There are no configuration notes.

**Attributes**

DBGDTR_EL0 is a 64-bit register.

**Field descriptions**

The DBGDTR_EL0 bit assignments are:

**HighWord, bits [63:32]**

Writes to this register set DTRRX to the value in this field and do not change RXfull.

Reads from this register return the value of DTRTX and do not change TXfull.

**LowWord, bits [31:0]**

Writes to this register set DTRTX to the value in this field and set TXfull to 1.

Reads from this register return the value of DTRRX and clear RXfull to 0.

**Accessing the DBGDTR_EL0:**

To access the DBGDTR_EL0:

MRS <Xt>, DBGDTR_EL0 ; Read DBGDTR_EL0 into Xt
MSR DBGDTR_EL0, <Xt> ; Write Xt to DBGDTR_EL0
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>011</td>
<td>0000</td>
<td>0100</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.7   DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If MDCR_EL2.TDA==1, Non-secure EL0 and EL1 read accesses to this register are trapped to EL2.

If MDCR_EL3.TDA==1, EL0, EL1, and EL2 read accesses to this register are trapped to EL3.

If MDSCR_EL1.TDCC==1, EL0 read accesses to this register are trapped to EL1.

Configurations

AArch64 System register DBGDTRRX_EL0 is architecturally mapped to AArch32 System register DBGDTRRXINT.

AArch64 System register DBGDTRRX_EL0 is architecturally mapped to External register DBGDTRRX_EL0.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:

Update DTRRX

Bits [31:0]

Update DTRRX.

If RXfull is set to 1, then reads of this register return the last value written to DTRRX and clear RXfull to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.
Accessing the DBGDTRRX_EL0:

To access the DBGDTRRX_EL0:

MRS <Xt>, DBGDTRRX_EL0 ; Read DBGDTRRX_EL0 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>011</td>
<td>0000</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.8  DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

**Purpose**

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL0 and EL1 write accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL0, EL1, and EL2 write accesses to this register are trapped to EL3.
- If MDSCR_EL1.TDCC==1, EL0 write accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register DBGDTRTX_EL0 is architecturally mapped to AArch32 System register DBGDTRTXint.

AArch64 System register DBGDTRTX_EL0 is architecturally mapped to External register DBGDTRTX_EL0.

**Attributes**

DBGDTRTX_EL0 is a 32-bit register.

**Field descriptions**

The DBGDTRTX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Return DTRTX</td>
</tr>
</tbody>
</table>

**Accessing the DBGDTRTX_EL0:**

To access the DBGDTRTX_EL0:
 MSR DBGDTRTX_EL0, <Xt> ; Write Xt to DBGDTRTX_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>011</td>
<td>0000</td>
<td>0101</td>
<td>00</td>
</tr>
</tbody>
</table>
D7.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If MDCR_EL2.TDOSA==1, Non-secure EL1 accesses to this register are trapped to EL2.

If MDCR_EL3.TDOSA==1, EL1 and EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register DBGPRCR_EL1 is architecturally mapped to AArch32 System register DBGPRCR.

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

Attributes

DBGPRCR_EL1 is a 32-bit register.

Field descriptions

The DBGPRCR_EL1 bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0

RES0

CORENPDRQ
```

Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

0    On a powerdown request, the system powers down the Core power domain.
1    On a powerdown request, the system emulates powerdown of the Core power domain.

In this emulation mode the Core power domain is not actually powered down.

Writes to this bit are permitted regardless of the state of the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request Core no powerdown regardless of whether invasive debug is permitted.
It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state.
When this register has an architecturally-defined reset value, this field resets to the value of EDPRCR.COREPURQ.
This field resets to its defined reset value on Cold reset.

**Accessing the DBGPRCR_EL1:**

To access the DBGPRCR_EL1:

MRS <Xt>, DBGPRCR_EL1 ; Read DBGPRCR_EL1 into Xt
MSR DBGPRCR_EL1, <Xt> ; Write Xt to DBGPRCR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0001</td>
<td>0100</td>
<td>100</td>
</tr>
</tbody>
</table>
### D7.3.10 DBGVCR32_EL2, Debug Vector Catch Register

The DBGVCR32_EL2 characteristics are:

**Purpose**

Allows access to the AArch32 register DBGVCR from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register DBGVCR32_EL2 is architecturally mapped to AArch32 System register DBGVCR.

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

**Attributes**

DBGVCR32_EL2 is a 32-bit register.

**Field descriptions**

The DBGVCR32_EL2 bit assignments are:

*When EL3 implemented and using AArch64:*

```
 31 30 29 28 27 26 25 24  8  7  6  5  4  3  2  1  0
 NSF NSI RES0 SI SP SSSU
```

- **NSF, bit [31]**

  FIQ vector catch enable in Non-secure state.
  The exception vector offset is 0x1C.

  When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

  This field resets to its defined reset value on Warm reset.
NSI, bit [30]
IRQ vector catch enable in Non-secure state.
The exception vector offset is 0x18.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

Bit [29]
Reserved, RES0.

NSD, bit [28]
Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

NSP, bit [27]
Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

NSS, bit [26]
Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

NSU, bit [25]
Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

Bits [24:8]
Reserved, RES0.

SF, bit [7]
FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

SI, bit [6]
IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**Bit [5]**

Reserved, RES0.

**SD, bit [4]**

Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**SP, bit [3]**

Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**SS, bit [2]**

Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**SU, bit [1]**

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**Bit [0]**

Reserved, RES0.

*When EL3 not implemented:*

```
<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>F</td>
<td>I</td>
<td>D</td>
<td>P</td>
<td>S</td>
<td>U</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:8]**

Reserved, RES0.
F, bit [7]
FIQ vector catch enable.
The exception vector offset is 0x1C.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

I, bit [6]
IRQ vector catch enable.
The exception vector offset is 0x18.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

Bit [5]
Reserved, RES0.

D, bit [4]
Data Abort vector catch enable.
The exception vector offset is 0x10.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

P, bit [3]
Prefetch Abort vector catch enable.
The exception vector offset 0x0C.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

S, bit [2]
Supervisor Call (SVC) vector catch enable.
The exception vector offset is 0x08.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

U, bit [1]
Undefined Instruction vector catch enable.
The exception vector offset is 0x04.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

Bit [0]
Reserved, RES0.

Accessing the DBGVCR32_EL2:
To access the DBGVCR32_EL2:
MRS <Xt>, DBGVCR32_EL2 ; Read DBGVCR32_EL2 into Xt
MSR DBGVCR32_EL2, <Xt> ; Write Xt to DBGVCR32_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>100</td>
<td>0000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.11 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1, where n is 0 to 15.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546 and *Software Access debug event* on page H3-5037. Subject to the prioritization rules:

- If EDSCR.TDA==1, and OSLSR.OSLK==0, EL1, EL2, and EL3 accesses to this register are trapped to Debug state.
- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register DBGWCR<n>_EL1 is architecturally mapped to AArch32 System register DBGWCR<n>.

AArch64 System register DBGWCR<n>_EL1 is architecturally mapped to External register DBGWCR<n>_EL1.

**Attributes**

DBGWCR<n>_EL1 is a 32-bit register.

**Field descriptions**

The DBGWCR<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>29</th>
<th>28</th>
<th>24</th>
<th>23</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>12</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>MASK</td>
<td>RES0</td>
<td>LBN</td>
<td>SSC</td>
<td>BAS</td>
<td>LSC</td>
<td>PAC</td>
<td>E</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

- 00000: No mask.
- 00001: Reserved.
- 00010: Reserved.
If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

**Bits [23:21]**

Reserved, RES0.

**WT, bit [20]**

Watchpoint type. Possible values are:

- 0 Unlinked data address match.
- 1 Linked data address match.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

**LBN, bits [19:16]**

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

**SSC, bits [15:14]**

Security state control. Determines the Security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

**HMC, bit [13]**

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.
BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<\text{n}>_EL1 is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxxxxx1</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1</td>
</tr>
<tr>
<td>xxxxx1x</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+1</td>
</tr>
<tr>
<td>xxxxx1xx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+2</td>
</tr>
<tr>
<td>xxxx1xxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<\text{n}>_EL1 addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;\text{n}&gt;_EL1[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx1xxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+4</td>
</tr>
<tr>
<td>xx1xxxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+5</td>
</tr>
<tr>
<td>x1xxxxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+6</td>
</tr>
<tr>
<td>1xxxxxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt;_EL1+7</td>
</tr>
</tbody>
</table>

If DBGWVR<\text{n}>_EL1[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<\text{n}>_EL1[2] == 1.

The valid values for BAS are 0b00000000, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made.

Possible values of this field are:

| 01 | Match instructions that load from a watchpointed address. |
| 10 | Match instructions that store to a watchpointed address. |
| 11 | Match instructions that load from or store to a watchpointed address. |

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.
When this register has an architecturally-defined reset value, this field resets to a value that is architecturally **UNKNOWN**.

This field resets to its defined reset value on Cold reset.

**E, bit [0]**

Enable watchpoint n. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Watchpoint disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Watchpoint enabled.</td>
</tr>
</tbody>
</table>

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally **UNKNOWN**.

This field resets to its defined reset value on Cold reset.

**Accessing the DBGWCR<n>_EL1:**

To access the DBGWCR<n>_EL1:

- MRS <Xt>, DBGWCR<n>_EL1 ; Read DBGWCR<n>_EL1 into Xt, where n is in the range 0 to 15
- MSR DBGWCR<n>_EL1, <Xt> ; Write Xt to DBGWCR<n>_EL1, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>n&lt;3:0&gt;</td>
<td>111</td>
</tr>
</tbody>
</table>
### D7.3.12 DBGWVR<\(n\)>_EL1, Debug Watchpoint Value Registers, \(n = 0 - 15\)

The DBGWVR<\(n\)>_EL1 characteristics are:

#### Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint \(n\) together with control register DBGWCR<\(n\)>_EL1, where \(n\) is 0 to 15.

#### Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

#### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546 and *Software Access debug event* on page H3-5037. Subject to the prioritization rules:

- If EDSCR.TDA==1, and OSLSR.OSLK==0, EL1, EL2, and EL3 accesses to this register are trapped to Debug state.
- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

#### Configurations

- AArch64 System register DBGWVR<\(n\)>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<\(n\)>.
- AArch64 System register DBGWVR<\(n\)>_EL1 is architecturally mapped to External register DBGWVR<\(n\)>_EL1.

#### Attributes

DBGWVR<\(n\)>_EL1 is a 64-bit register.

#### Field descriptions

The DBGWVR<\(n\)>_EL1 bit assignments are:

![Field assignments diagram]

**RESS, bits [63:49]**

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

**VA, bits [48:2]**

Bits[48:2] of the address value for comparison.

ARM deprecates setting DBGWVR<\(n\)>_EL1[2] == 1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Cold reset.
Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>_EL1:

To access the DBGWVR<n>_EL1:

MRS <Xt>, DBGWVR<n>_EL1; Read DBGWVR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGWVR<n>_EL1, <Xt>; Write Xt to DBGWVR<n>_EL1, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>n&lt;3:0&gt;</td>
<td>110</td>
</tr>
</tbody>
</table>

D7.3.13 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register DLR_EL0[31:0] is architecturally mapped to AArch32 System register DLR.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

The DLR_EL0 bit assignments are:

Restart address

Bits [63:0]

Restart address.

Accessing the DLR_EL0:

To access the DLR_EL0:

MRS <Xt>, DLR_EL0 ; Read DLR_EL0 into Xt
MSR DLR_EL0, <Xt> ; Write Xt to DLR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.3.14 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

**Purpose**

Holds the saved process state on entry to Debug state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register DSPSR_EL0 is architecturally mapped to AArch32 System register DSPSR.

**Attributes**

DSPSR_EL0 is a 32-bit register.

**Field descriptions**

The DSPSR_EL0 bit assignments are:

*When exiting Debug state to AArch32:*

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19</th>
<th>16 15</th>
<th>10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>N, bit [31]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Z, bit [30]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C, bit [29]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>V, bit [28]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Q, bit [27]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

N, bit [31]

Copied to CPSR.N on exiting Debug state.

Z, bit [30]

Copied to CPSR.Z on exiting Debug state.

C, bit [29]

Copied to CPSR.C on exiting Debug state.

V, bit [28]

Copied to CPSR.V on exiting Debug state.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.
IT[1:0], bits [26:25]
If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
RES0.
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness Execution State bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that Debug state was entered from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

When entering Debug state from AArch64 and exiting Debug state to AArch64:

```
  31 30 29 28 27 22 21 20 19 10  9  8  7  6  5  4  3  0
    N  Z  C  V  RES0  SS  IL  RES0  D  A  I  F  M[3:0]  
         M[4]  RES0
```
N, bit [31]
Set to the value of the N condition flag on entering Debug state, and copied to the N condition flag on exiting Debug state.

Z, bit [30]
Set to the value of the Z condition flag on entering Debug state, and copied to the Z condition flag on exiting Debug state.

C, bit [29]
Set to the value of the C condition flag on entering Debug state, and copied to the C condition flag on exiting Debug state.

V, bit [28]
Set to the value of the V condition flag on entering Debug state, and copied to the V condition flag on exiting Debug state.

Bits [27:22]
Reserved, RES0.

SS, bit [21]
Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

Bits [19:10]
Reserved, RES0.

D, bit [9]
Process state D mask. The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are not masked.</td>
</tr>
<tr>
<td>1</td>
<td>Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current Exception level are masked.</td>
</tr>
</tbody>
</table>

When the target Exception level of the debug exception is not than the current Exception level, the exception is not masked by this bit.

A, bit [8]
SError (System Error) mask bit. The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exception not masked.</td>
</tr>
<tr>
<td>1</td>
<td>Exception masked.</td>
</tr>
</tbody>
</table>

I, bit [7]
IRQ mask bit. The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exception not masked.</td>
</tr>
<tr>
<td>1</td>
<td>Exception masked.</td>
</tr>
</tbody>
</table>

F, bit [6]
FIQ mask bit. The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exception not masked.</td>
</tr>
<tr>
<td>1</td>
<td>Exception masked.</td>
</tr>
</tbody>
</table>

Bit [5]
Reserved, RES0.
M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

0   Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 mode that Debug state was entered from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EL0t</td>
</tr>
<tr>
<td>0010</td>
<td>EL1t</td>
</tr>
<tr>
<td>0011</td>
<td>EL1h</td>
</tr>
<tr>
<td>0100</td>
<td>EL2t</td>
</tr>
<tr>
<td>0101</td>
<td>EL2h</td>
</tr>
<tr>
<td>0110</td>
<td>EL3t</td>
</tr>
<tr>
<td>0111</td>
<td>EL3h</td>
</tr>
</tbody>
</table>

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

- M[1] is unused and is RES0 for all non-reserved values.
- M[0] is used to select the SP:
  - 0 means the SP is always SP0.
  - 1 means the exception SP is determined by the EL.

**Accessing the DSPSR_EL0:**

To access the DSPSR_EL0:

MRS <Xt>, DSPSR_EL0 ; Read DSPSR_EL0 into Xt
MSR DSPSR_EL0, <Xt> ; Write Xt to DSPSR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.15 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

**Purpose**

Enables interrupt requests to be signaled based on the DCC status flags.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register MDCCINT_EL1 is architecturally mapped to AArch32 System register DBGDCCINT.

**Attributes**

MDCCINT_EL1 is a 32-bit register.

**Field descriptions**

The MDCCINT_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RX TX</td>
<td>RES0</td>
</tr>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bit [31]**

Reserved, RES0.

**RX, bit [30]**

DCC interrupt request enable control for DTRRX. Enables a common COMMRQ interrupt request to be signaled based on the DCC status flags.

- 0: No interrupt request generated by DTRRX.
- 1: Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Warm reset.
TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0  No interrupt request generated by DTRTX.
- 1  Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Warm reset.

Bits [28:0]

Reserved, RES0.

**Accessing the MDCCINT_EL1:**

To access the MDCCINT_EL1:

MRS <Xt>, MDCCINT_EL1 ; Read MDCCINT_EL1 into Xt
MSR MDCCINT_EL1, <Xt> ; Write Xt to MDCCINT_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.16 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

Purpose

Main control register for the debug implementation, containing flow-control flags for the DCC. This is an internal, read-only view.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL0 and EL1 read accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL0, EL1, and EL2 read accesses to this register are trapped to EL3.
- If MDSCR_EL1.TDCC==1, EL0 read accesses to this register are trapped to EL1.

Configurations

AArch64 System register MDCCSR_EL0 is architecturally mapped to AArch32 System register DBGDSCRint.

Attributes

MDCCSR_EL0 is a 32-bit register.

Field descriptions

The MDCCSR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28 19 18 15 14 13 12 11 6 5 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0  RAZ  RES0  RAZ  RES0  RAZ  RES0  RAZ</td>
</tr>
<tr>
<td>RES0  RXfull  RES0  TXfull  RES0  RAZ  RES0</td>
</tr>
</tbody>
</table>

Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the EDSRCR.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the EDSRCR.

Bits [28:19]

Reserved, RES0.
Bits [18:15]
Reserved, RAZ. Hardware must implement this field as RAZ. Software must not rely on this field being RAZ.

Bits [14:13]
Reserved, RES0.

Bit [12]
Reserved, RAZ. Hardware must implement this field as RAZ. Software must not rely on this field being RAZ.

Bits [11:6]
Reserved, RES0.

Bits [5:2]
Reserved, RAZ. Hardware must implement this field as RAZ. Software must not rely on this field being RAZ.

Bits [1:0]
Reserved, RES0.

Accessing the MDCCSR_EL0:

To access the MDCCSR_EL0:

MRS <Xt>, MDCCSR_EL0 ; Read MDCCSR_EL0 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>011</td>
<td>0000</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.17 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

Purpose

Provides EL2 configuration options for self-hosted debug and the Performance Monitors extension.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If MDCR_EL3.TDA==1, EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register MDCR_EL2 is architecturally mapped to AArch32 System register HDCR.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

MDCR_EL2 is a 32-bit register.

Field descriptions

The MDCR_EL2 bit assignments are:

```
31  | 12 11 10 9 8 7 6 5 4 0
    | RES0          HPMN
    | TPMCR         TPM
    | HPME          TPM
    | TDE           TME
    | TDA           TDOSA
    | TDRA

Bits [31:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure System register accesses to the Debug ROM registers to EL2. This trap is from:

- Non-secure EL0 using AArch32.
- Non-secure EL1, regardless of which Execution state it is using.

0 Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are not trapped to EL2.
1  Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are
trapped to EL2.

The registers for which accesses are trapped are as follows:

AArch64:  MDRAR_EL1.
AArch32:  DBGDRAR, DBGDSAR.

If MDCR_EL2.TDE == 1 or HCR_EL2.TGE == 1, behavior is as if this bit is 1 other than for the
purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to a value that is
architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

TDOSA, bit [10]

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the
powerdown debug registers to EL2, from both Execution states:

0  Non-secure EL1 System register accesses to the powerdown debug registers are not
trapped to EL2.

1  Non-secure EL1 System register accesses to the powerdown debug registers are trapped
to EL2.

The registers for which accesses are trapped are as follows:

AArch64:  OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, and the DBGPRCR_EL1.
AArch32:  DBGOSLSR, DBGOSLAR, DBGOSDLR, and the DBGPRCR.

AArch64 and AArch32:

•  Any IMPLEMENTATION DEFINED integration registers.
•  Any IMPLEMENTATION DEFINED register with similar functionality that the implementation
specifies as trapped by this bit.

Note

These registers are not accessible at EL0.

If MDCR_EL2.TDE == 1 or HCR_EL2.TGE == 1, behavior is as if this bit is 1 other than for the
purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to a value that is
architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

TDA, bit [9]

Trap Debug Access. Traps Non-secure EL0 and EL1 System register accesses to those debug
System registers that are not trapped by either of the following:

•  MDCR_EL2.TDRA.
•  MDCR_EL2.TDOSA.

0  Has no effect on System register accesses to the debug registers.

1  Non-secure EL0 or EL1 System register accesses to the debug registers, other than the
registers trapped by MDCR_EL2.TDRA and MDCR_EL2.TDOSA, are trapped to EL2,
from both Execution states.

MDCR_EL2.TDA does not trap accesses to the DBGDTRRX_EL0, DBGDTRTX_EL0, or
DBGDTR_EL0 when the PE is in Debug state.

If MDCR_EL2.TDE == 1 or HCR_EL2.TGE == 1, behavior is as if this bit is 1 other than for the
purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to a value that is
architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

**TDE, bit [8]**

Route Software debug exceptions from Non-secure EL1 and EL0 to EL2. Also enables traps on all debug register accesses to EL2.

If `HCR_EL2.TGE == 1`, then this bit is ignored and treated as though it is 1 other than for the value read back from MDCR_EL2.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**HPME, bit [7]**

Hypervisor Performance Monitors Enable. The possible values of this bit are:

- 0 EL2 Performance Monitors disabled.
- 1 EL2 Performance Monitors enabled.

When the value of this bit is 1, the Performance Monitors counters that are reserved for use from EL2 or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**TPM, bit [6]**

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to EL2, from both Execution states:

- 0 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are not trapped to EL2.
- 1 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to EL2.

**Note**

- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**TPMCR, bit [5]**

Trap `PMCR_EL0` or `PMCR` accesses. Traps Non-secure EL0 and EL1 accesses to the `PMCR_EL0` or `PMCR` to EL2.

- 0 Non-secure EL0 and EL1 accesses to the `PMCR_EL0` or `PMCR` are not trapped to EL2.
- 1 Non-secure EL0 and EL1 accesses to the `PMCR_EL0` or `PMCR` are trapped to EL2.

**Note**

- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

**HPMN, bits [4:0]**

Defines the number of Performance Monitors counters that are accessible from Non-secure EL0 and EL1 modes.

If the Performance Monitors extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. For counter n in Non-secure state:

- If n is in the range 0<=n<HPMN, the counter is accessible from EL1 and EL2, and from EL0 if permitted by PMUSERENR_EL0. PMCR_EL0.E enables the operation of counters in this range.
- If n is in the range HPMN<=n<PMCR_EL0.N, the counter is accessible only from EL2. MDCR_EL2.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR_EL0.N, then the behavior in Non-secure EL0 and EL1 is CONSTRAINED UNPREDICTABLE, and one of the following must happen:

- The number of counters accessible is an UNKNOWN non-zero value less than PMCR_EL0.N.
- There is no access to any counters.

For reads of MDCR_EL2.HPMN by EL2 or higher, if this field is set to 0 or to a value larger than PMCR_EL0.N, the PE must return a CONSTRAINED UNPREDICTABLE value being one of:

- PMCR_EL0.N.
- The value that was written to MDCR_EL2.HPMN.
- (The value that was written to MDCR_EL2.HPMN) modulo 2^h, where h is the smallest number of bits required for a value in the range 0 to PMCR_EL0.N.

When this register has an architecturally-defined reset value, this field resets to the value of PMCR_EL0.N.

This field resets to its defined reset value on Warm reset.

**Accessing the MDCR_EL2:**

To access the MDCR_EL2:

MRS <Xt>, MDCR_EL2 ; Read MDCR_EL2 into Xt
MSR MDCR_EL2, <Xt> ; Write Xt to MDCR_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.3.18  **MDCR_EL3, Monitor Debug Configuration Register (EL3)**

The MDCR_EL3 characteristics are:

**Purpose**

Provides EL3 configuration options for self-hosted debug and the Performance Monitors extension.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register MDCR_EL3 can be mapped to AArch32 System register SDCR, but this is not architecturally mandated.

**Attributes**

MDCR_EL3 is a 32-bit register.

**Field descriptions**

The MDCR_EL3 bit assignments are:

```
   31  22  21  20  19  18  17  16  15  14  13  11  10  9  8  7  6  5  0
   RES0    RES0    RES0
   EPMAD   EDAD    RES0   SPME   SDD |
   TPM     RES0    TDA    TDOSA  SPD32
```

**Bits [31:22]**

Reserved, RES0.

**EPMAD, bit [21]**

External debug interface Performance Monitors registers disable. This disables access to these registers by an external debugger:

- **0** Access to Performance Monitors registers from external debugger is permitted.
- **1** Access to Performance Monitors registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors extension is not implemented or does not support external debug interface accesses this bit is RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Warm reset.
EDAD, bit [20]

External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger:

0  Access to breakpoint and watchpoint registers from external debugger is permitted.
1  Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

When this register has an architecturally-defined reset value, this field resets to 0.
This field resets to its defined reset value on Warm reset.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure Performance Monitors enable. This allows event counting in Secure state:

0  Event counting prohibited in Secure state, unless overridden by the IMPLEMENTATION DEFINED authentication interface.
1  Event counting allowed in Secure state, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

When this register has an architecturally-defined reset value, this field resets to 0.
This field resets to its defined reset value on Warm reset.

SDD, bit [16]

AArch64 Secure self-hosted invasive debug disable. Disables Software debug exceptions in Secure state, other than Software breakpoint instruction.

0  Debug exceptions from Secure EL0 are enabled, and debug exceptions from Secure EL1 are enabled if the value of MDSCR_EL1.KDE is 1 and the value of PSTATE.D is 0.
1  Software debug events, other than software breakpoint instruction debug events, are disabled from all Exception levels in Secure state.

The SDD bit is ignored unless both of the following are true:
•  The PE is in Secure state.
•  Secure EL1 is using AArch64.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
This field resets to its defined reset value on Warm reset.

SPD32, bits [15:14]

AArch32 Secure self-hosted privileged invasive debug control. Enables or disables debug exceptions from Secure state if Secure EL1 is using AArch32, other than Software Breakpoint instructions. Valid values for this field are:

00  Legacy mode. Debug exceptions from Secure EL1 are enabled by the IMPLEMENTATION DEFINED authentication interface.
10  Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
11  Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as 0000. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.
This field has no effect on Software Breakpoint instructions. These are always enabled.
This field is:
•  Ignored if either:
  —  The PE is in Secure state.
— Secure EL1 is using AArch64.
  
  • RES0 if the implementation does not support EL1 using AArch32.

If Secure EL1 is using AArch32 then:
  
  • If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
  
  • Otherwise, debug exceptions from Secure EL0 are enabled only if the value of SDER32_EL3.SUIDEN is 1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**Bits [13:11]**

Reserved, RES0.

**TDOSA, bit [10]**

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3, from both Security states and both Execution states:

0  EL2 and EL1 System register accesses to the powerdown debug registers are not trapped to EL3.

1  EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3.

The registers for which accesses are trapped are as follows:

AArch64: OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1.

AArch32: DBGOSLAR, DBGOSLSR, DBGOSDLR, DBGPRCR.

AArch64 and AArch32:

• Any IMPLEMENTATION DEFINED integration registers.

• Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**TDA, bit [9]**

Trap Debug Access. Traps EL2, EL1, and EL0 System register accesses to those debug System registers that cannot be trapped using the MDCR_EL3.TDOSA field. When MDCR_EL3.TDA is:

0  EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA, are not trapped to EL3.

1  EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA, are trapped to EL3, from both Security states and both Execution states.

MDCR_EL3.TDA does not trap accesses to the DBGDTRRX_EL0, DBGDTRTX_EL0, or DBGDTR_EL0 when the PE is in Debug state.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**Bits [8:7]**

Reserved, RES0.
TPM, bit [6]

Trap Performance Monitors accesses. Traps EL2, EL1, and EL0 accesses to all Performance Monitors registers to EL3, from both Security states and both Execution states.

0  EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are not trapped to EL3.

1  EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3.

--- Note ---

If the Performance Monitors extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

Bits [5:0]

Reserved, RES0.

Accessing the MDCR_EL3:

To access the MDCR_EL3:

MRS <Xt>, MDCR_EL3 ; Read MDCR_EL3 into Xt
MSR MDCR_EL3, <Xt> ; Write Xt to MDCR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0001</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.3.19 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

**Purpose**

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDRA==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 read accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register MDRAR_EL1 is architecturally mapped to AArch32 System register DBGDRAR.

**Attributes**

MDRAR_EL1 is a 64-bit register.

**Field descriptions**

The MDRAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>48 to 47</td>
<td>ROMADD[47:12]</td>
</tr>
<tr>
<td>12 to 11</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>2</td>
<td>Valid</td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**ROMADD[47:12], bits [47:12]**

Bits[47:12] of the ROM table physical address.

- If the physical address size in bits (PSize) is less than 48 then the register bits corresponding to ROMADD [47:PSize] are RES0.
- Bits [11:0] of the ROM table physical address are zero.
- ARM strongly recommends that bits ROMADD[(PSize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

**Bits [11:2]**

Reserved, RES0.

**Valid, bits [1:0]**

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

- 00 ROM Table address is not valid
11  ROM Table address is valid.
Other values are reserved.
If no memory-mapped debug components are implemented, this field is RES0.

**Accessing the MDRAR_EL1:**

To access the MDRAR_EL1:

```c
MRS <Xt>, MDRAR_EL1 ; Read MDRAR_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.3.20 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.

If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register MDSCR_EL1 is architecturally mapped to AArch32 System register DBGDSRExt.

Attributes

MDSCR_EL1 is a 32-bit register.

Field descriptions

The MDSCR_EL1 bit assignments are:

Bit [31]

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of EDSR.RXfull.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.
When $\text{OSLSR\_EL1.OSLK} == 1$ (the OS lock is locked), this bit is RW.

**TXfull, bit [29]**

Used for save/restore of $\text{EDSCR.TXfull}$.

When $\text{OSLSR\_EL1.OSLK} == 0$ (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When $\text{OSLSR\_EL1.OSLK} == 1$ (the OS lock is locked), this bit is RW.

**Bit [28]**

Reserved, RES0.

**RXO, bit [27]**

Used for save/restore of $\text{EDSCR.RXO}$.

When $\text{OSLSR\_EL1.OSLK} == 0$ (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When $\text{OSLSR\_EL1.OSLK} == 1$ (the OS lock is locked), this bit is RW.

**TXU, bit [26]**

Used for save/restore of $\text{EDSCR.TXU}$.

When $\text{OSLSR\_EL1.OSLK} == 0$ (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When $\text{OSLSR\_EL1.OSLK} == 1$ (the OS lock is locked), this bit is RW.

**Bits [25:24]**

Reserved, RES0.

**INTdis, bits [23:22]**

Used for save/restore of $\text{EDSCR.INTdis}$.

When $\text{OSLSR\_EL1.OSLK} == 0$ (the OS lock is unlocked), this field is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When $\text{OSLSR\_EL1.OSLK} == 1$ (the OS lock is locked), this field is RW.

**TDA, bit [21]**

Used for save/restore of $\text{EDSCR.TDA}$.

When $\text{OSLSR\_EL1.OSLK} == 0$ (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When $\text{OSLSR\_EL1.OSLK} == 1$ (the OS lock is locked), this bit is RW.

**Bits [20:19]**

Reserved, RES0.

**Bits [18:16]**

Reserved, RAZ/WI. Hardware must implement this as RAZ/WI. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

**MDE, bit [15]**

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector catch debug exceptions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Breakpoint, Watchpoint, and Vector catch debug exceptions disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Breakpoint, Watchpoint, and Vector catch debug exceptions enabled.</td>
</tr>
</tbody>
</table>

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.
HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable Software debug events within EL_D.

Permitted values are:

0  Software debug events, other than Software breakpoint instructions, disabled within EL_D.
1  Software debug events enabled within EL_D.
RES0 if EL_D is using AArch32.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

TDCC, bit [12]

Traps EL0 accesses to the DCC registers to EL1, from both Execution states:

0  EL0 using AArch64: EL0 accesses to the MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 registers are not trapped to EL1.
   EL0 using AArch32: EL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIIDR, DBGDSAR, and DBGDRAR registers are not trapped to EL1.
1  EL0 using AArch64: EL0 accesses to the MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 registers are trapped to EL1.
   EL0 using AArch32: EL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIIDR, DBGDSAR, and DBGDRAR registers are trapped to EL1.

___ Note ___

All accesses to these AArch32 registers are trapped, including LDC and STC accesses to DBGDTRTXint and DBGDTRRXint, and MRRC accesses to DBGDSAR and DBGDRAR.

___

Traps of AArch32 PL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR. ERR.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [5:1]

Reserved, RES0.
SS, bit [0]

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

0  Software step disabled
1  Software step enabled.

RES0 if EL_D is using AArch32.

When this register has an architecturally-defined reset value, this field resets to a value that is
architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

**Accessing the MDSCR_EL1:**

To access the MDSCR_EL1:

MRS <Xt>, MDSCR_EL1 ; Read MDSCR_EL1 into Xt
MSR MDSCR_EL1, <Xt> ; Write Xt to MDSCR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.3.21 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

**Purpose**

Used to control the OS Double Lock.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDOSA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDOSA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register OSDLR_EL1 is architecturally mapped to AArch32 System register DBGOSDLR.

**Attributes**

OSDLR_EL1 is a 32-bit register.

**Field descriptions**

The OSDLR_EL1 bit assignments are:

![Field Diagram]

**Bits [31:1]**

Reserved, RES0.

**DLK, bit [0]**

OS Double Lock control bit. Possible values are:

- 0   OS Double Lock unlocked.
- 1   OS Double Lock locked, if DBGPRCR_EL1.CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Warm reset.

**Accessing the OSDLR_EL1:**

To access the OSDLR_EL1:

```
MRS <Xt>, OSDLR_EL1 ; Read OSDLR_EL1 into Xt
```
MSR OSDLR_EL1, <Xt> ; Write Xt to OSDLR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0001</td>
<td>0011</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.3.22   OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

**Purpose**

Used for save/restore of DBGDTRRX_EL0. It is a component of the Debug Communications Channel.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of OSDTRRX_EL1 when the OS lock is unlocked.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register OSDTRRX_EL1 is architecturally mapped to AArch32 System register DBGDTRRXext.

**Attributes**

OSDTRRX_EL1 is a 32-bit register.

**Field descriptions**

The OSDTRRX_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Update DTRRX without side-effect</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

- Update DTRRX without side-effect.
- Writes to this register update the value in DTRRX and do not change RXfull.
- Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

**Accessing the OSDTRRX_EL1:**

To access the OSDTRRX_EL1:

- MRS <Xt>, OSDTRRX_EL1; Read OSDTRRX_EL1 into Xt
- MSR OSDTRRX_EL1, <Xt>; Write Xt to OSDTRRX_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.3.23   OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit

The OSDTRTX_EL1 characteristics are:

**Purpose**

Used for save/restore of DBGDTRTX_EL0. It is a component of the Debug Communications Channel.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of OSDTRTX_EL1 when the OS lock is unlocked.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register OSDTRTX_EL1 is architecturally mapped to AArch32 System register DBGDTRTXext.

**Attributes**

OSDTRTX_EL1 is a 32-bit register.

**Field descriptions**

The OSDTRTX_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return DTRTX without side-effect</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Return DTRTX without side-effect. Reads of this register return the value in DTRTX and do not change TXfull. Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

**Accessing the OSDTRTX_EL1**:

To access the OSDTRTX_EL1:

MRS <Xt>, OSDTRTX_EL1 ; Read OSDTRTX_EL1 into Xt
MSR OSDTRTX_EL1, <Xt> ; Write Xt to OSDTRTX_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>011</td>
<td>010</td>
</tr>
</tbody>
</table>
### OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

**Purpose**

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDA==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TDA==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

- AArch64 System register OSECCR_EL1 is architecturally mapped to AArch32 System register DBGOSECCR.
- AArch64 System register OSECCR_EL1 is architecturally mapped to External register EDECCR.

**Attributes**

OSECCR_EL1 is a 32-bit register.

**Field descriptions**

The OSECCR_EL1 bit assignments are:

**When OSLSR.OSLK==1:**

```
  31  0
     EDECCR
```

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

**Accessing the OSECCR_EL1:**

To access the OSECCR_EL1:

- MRS <Xt>, OSECCR_EL1 ; Read OSECCR_EL1 into Xt
- MSR OSECCR_EL1, <Xt> ; Write Xt to OSECCR_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0000</td>
<td>0110</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.3.25 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

**Purpose**

Used to lock or unlock the OS lock.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TDOSA==1, Non-secure EL1 write accesses to this register are trapped to EL2.
- If MDCR_EL3.TDOSA==1, EL1 and EL2 write accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register OSLAR_EL1 is architecturally mapped to AArch32 System register DBGOSLR.

AArch64 System register OSLAR_EL1 is architecturally mapped to External register OSLAR_EL1.

**Attributes**

OSLAR_EL1 is a 32-bit register.

**Field descriptions**

The OSLAR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30</td>
<td></td>
</tr>
<tr>
<td>29</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td>OSLK</td>
</tr>
</tbody>
</table>

Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.
Use OSLSR_EL1.OSLK to check the current status of the lock.

**Accessing the OSLAR_EL1:**

To access the OSLAR_EL1:

MSR OSLAR_EL1, <Xt> ; Write Xt to OSLAR_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.3.26 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

**Purpose**
Provides the status of the OS lock.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If MDCR_EL2.TDOSA==1, Non-secure EL1 read accesses to this register are trapped to EL2.
If MDCR_EL3.TDOSA==1, EL1 and EL2 read accesses to this register are trapped to EL3.

**Configurations**
AArch64 System register OSLSR_EL1 is architecturally mapped to AArch32 System register DBGOSLSR.

**Attributes**
OSLSR_EL1 is a 32-bit register.

**Field descriptions**
The OSLSR_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:4]**
Reserved, RES0.

**OSLM[0]**
See below for description of the OSLM field.

**nTT, bit [2]**
Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

**OSLK, bit [1]**
OS Lock Status. The possible values are:
0 OS lock unlocked.
1 OS lock locked.
The OS lock is locked and unlocked by writing to the OS Lock Access Register. When this register has an architecturally-defined reset value, this field resets to 1. This field resets to its defined reset value on Cold reset.

**OSLM[0], bit [0]**

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In ARMv8 these bits are as follows:

- 10: OS lock implemented. DBGOSRR not implemented.
- All other values are reserved.

**Accessing the OSLSR_EL1:**

To access the OSLSR_EL1:

MRS <Xt>, OSLSR_EL1 ; Read OSLSR_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>000</td>
<td>0001</td>
<td>0001</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.3.27 SDER32_EL3, AArch32 Secure Debug Enable Register

The SDER32_EL3 characteristics are:

**Purpose**

Allows access to the AArch32 register SDER from AArch64 state only. Its value has no effect on execution in AArch64 state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register SDER32_EL3 is architecturally mapped to AArch32 System register SDER.

If EL1 is AArch64 only, this register is UNDEFINED.

**Attributes**

SDER32_EL3 is a 32-bit register.

**Field descriptions**

The SDER32_EL3 bit assignments are:

```
   31  2  1  0
RES0
SUIDEN
SUNIDEN
```

**Bits [31:0]**

Reserved, RES0.

**SUNIDEN, bit [1]**

Secure User Non-Invasive Debug Enable:

- 0 Performance Monitors event counting prohibited in Secure EL0 unless allowed by MDCR_EL3.SPME or the IMPLEMENTATION DEFINED authentication interfaceExternalSecureNonInvasiveDebugEnabled().
- 1 Performance Monitors event counting allowed in Secure EL0.

**SUIDEN, bit [0]**

Secure User Invasive Debug Enable:

- 0 Debug exceptions other than Software Breakpoint Instruction exceptions from Secure EL0 are disabled, unless enabled by MDCR_EL3.SPD32.
- 1 Debug exceptions from Secure EL0 are enabled.
Accessing the SDER32_EL3:

To access the SDER32_EL3:

MRS <Xt>, SDER32_EL3 ; Read SDER32_EL3 into Xt
MSR SDER32_EL3, <Xt> ; Write Xt to SDER32_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>0001</td>
<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.4 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.
D7.4.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

PMCCFILTR_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to 0b111111.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

Configurations

AArch64 System register PMCCFILTR_EL0 is architecturally mapped to AArch32 System register PMCCFILTR.

AArch64 System register PMCCFILTR_EL0 is architecturally mapped to External register PMCCFILTR_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>P U M RES0</td>
<td></td>
</tr>
</tbody>
</table>

- NSK
- NSU
- NSH

P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0: Count cycles in EL1.
- 1: Do not count cycles in EL1.
U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0  Count cycles in EL0.
1  Do not count cycles in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted. Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure User mode filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted. Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0  Do not count cycles in EL2.
1  Count cycles in EL2.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted. Otherwise, cycles in Secure EL3 are not counted.

Bits [25:0]

Reserved, RES0.

Accessing the PMCCFILTR_EL0:

To access the PMCCFILTR_EL0:

MRS <Xt>, PMCCFILTR_EL0 ; Read PMCCFILTR_EL0 into Xt
MSR PMCCFILTR_EL0, <Xt> ; Write Xt to PMCCFILTR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>111</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.4.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D5-1850 for more information.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If `MDCR_EL2.TPM==1`, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.

If `MDCR_EL3.TPM==1`, EL0, EL1, and EL2 accesses to this register are trapped to EL3.

If `PMUSERENR_EL0.CR==0`, and `PMUSERENR_EL0.EN==0`, EL0 read accesses to this register are trapped to EL1.

If `PMUSERENR_EL0.EN==0`, EL0 write accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMCCNTR_EL0 is architecturally mapped to AArch32 System register PMCCNTR.

AArch64 System register PMCCNTR_EL0 is architecturally mapped to External register PMCCNTR_EL0.

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMCCNTR_EL0 is a 64-bit register.

**Field descriptions**

The PMCCNTR_EL0 bit assignments are:

**CCNT, bits [63:0]**

Cycle count. Depending on the values of PMCR_EL0.[LC,D], this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.
Accessing the PMCCNTR_EL0:

To access the PMCCNTR_EL0:

MRS <Xt>, PMCCNTR_EL0 ; Read PMCCNTR_EL0 into Xt
MSR PMCCNTR_EL0, <Xt> ; Write Xt to PMCCNTR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1101</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.4.3 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

**Purpose**
Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:
- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 read accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 read accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 read accesses to this register are trapped to EL1.

**Configurations**
AArch64 System register PMCEID0_EL0 is architecturally mapped to AArch32 System register PMCEID0.
AArch64 System register PMCEID0_EL0 is architecturally mapped to External register PMCEID0_EL0.

**Attributes**
PMCEID0_EL0 is a 32-bit register.

**Field descriptions**
The PMCEID0_EL0 bit assignments are:

```
   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 09 08 07 06 05 04 03 02 01 00
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| ID[31:0] |
```

**ID[31:0], bits [31:0]**
PMCEID0_EL0[n] maps to event n. For a list of event numbers and descriptions, see *Events, Event numbers and mnemonics on page D5-1865*.

For each bit:
- 0 The common event is not implemented.
- 1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.
Accessing the PMCEID0_EL0:

To access the PMCEID0_EL0:

MRS <Xt>, PMCEID0_EL0 ; Read PMCEID0_EL0 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 read accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 read accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 read accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMCEID1_EL0 is architecturally mapped to AArch32 System register PMCEID1.

AArch64 System register PMCEID1_EL0 is architecturally mapped to External register PMCEID1_EL0.

**Attributes**

PMCEID1_EL0 is a 32-bit register.

**Field descriptions**

The PMCEID1_EL0 bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID[63:32]</td>
<td></td>
</tr>
</tbody>
</table>
```

**ID[63:32], bits [31:0]**

PMCEID1_EL0[n] maps to event (n + 32). For a list of event numbers and descriptions, see Events, Event numbers and mnemonics on page D5-1865.

For each bit:

- 0 The common event is not implemented.
- 1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.
Accessing the PMCEID1_EL0:

To access the PMCEID1_EL0:

MRS <Xt>, PMCEID1_EL0 ; Read PMCEID1_EL0 into Xt

Register access is encoded as follows:

</table>
D7.4.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

**Purpose**

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMCNTENCLR_EL0 is architecturally mapped to AArch32 System register PMCNTENCLR.

AArch64 System register PMCNTENCLR_EL0 is architecturally mapped to External register PMCNTENCLR_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMCNTENCLR_EL0 is a 32-bit register.

**Field descriptions**

The PMCNTENCLR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;x&gt;, bit [x]</td>
<td></td>
</tr>
</tbody>
</table>

- **C, bit [31]**

  PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:
  - 0: When read, means the cycle counter is disabled. When written, has no effect.
  - 1: When read, means the cycle counter is enabled. When written, disables the cycle counter.

- **P<x>, bit [x], for x = 0 to 30**

  Event counter disable bit for PMEVCNTR<x>.
  - Bits [30:N] are RAZ/WI.
  - When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.
Possible values of each bit are:

0  When read, means that PMEVCNTR<\text{x}> is disabled. When written, has no effect.
1  When read, means that PMEVCNTR<\text{x}> is enabled. When written, disables PMEVCNTR<\text{x}>.

**Accessing the PMCNTENCLR_EL0:**

To access the PMCNTENCLR_EL0:

\[
\text{MRS } \langle X_t \rangle, \text{ PMCNTENCLR_EL0 } \quad \text{Read PMCNTENCLR_EL0 into } X_t \\
\text{MSR PMCNTENCLR_EL0, } \langle X_t \rangle \quad \text{Write } X_t \text{ to PMCNTENCLR_EL0}
\]

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1100</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.4.6 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

**Purpose**

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<<>. Reading this register shows which counters are enabled.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMCNTENSET_EL0 is architecturally mapped to AArch32 System register PMCNTENSET.

AAArch64 System register PMCNTENSET_EL0 is architecturally mapped to External register PMCNTENSET_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMCNTENSET_EL0 is a 32-bit register.

**Field descriptions**

The PMCNTENSET_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;x&gt;, bit [x]</td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

- 0: When read, means the cycle counter is disabled. When written, has no effect.
- 1: When read, means the cycle counter is enabled. When written, enables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter enable bit for PMEVCNTR<<>. Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.
Possible values of each bit are:

0  When read, means that PMEVCNTR<\(x\)> is disabled. When written, has no effect.
1  When read, means that PMEVCNTR<\(x\)> event counter is enabled. When written, enables PMEVCNTR<\(x\)>.

Accessing the PMCNTENSET_EL0:

To access the PMCNTENSET_EL0:

MRS \(<Xt>, PMCNTENSET_EL0\); Read PMCNTENSET_EL0 into \(Xt\)
MSR PMCNTENSET_EL0, \(<Xt>\); Write \(Xt\) to PMCNTENSET_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1100</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.4.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

**Purpose**

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL2.TPMD==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMCR_EL0 is architecturally mapped to AArch32 System register PMCR.

AArch64 System register PMCR_EL0 is architecturally mapped to External register PMCR_EL0.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMCR_EL0 is a 32-bit register.

**Field descriptions**

The PMCR_EL0 bit assignments are:

```
  31  24  23  16  15  11  10  7  6  5  4  3  2  1  0
  IMP  IDCODE  N  RES0  LCP  X  D  C  P  E
```

**IMP, bits [31:24]**

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the MIDR.

**IDCODE, bits [23:16]**

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.
N, bits [15:11]

Number of event counters. If EL2 is supported, then in Non-secure EL1 and EL0, this field returns the value of MDCR_EL2.HPMN.

Otherwise, this field is RO with an IMPLEMENTATION DEFINED value that indicates the number of counters implemented.

The value of this field is the number of counters implemented, from 0b00000 for no counters to 0b11111 for 31 counters.

An implementation can implement only the Cycle Count Register, PMCCNTR_EL0. This is indicated by a value of 0b00000 for the N field.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR_EL0 bit generates an overflow recorded by PMOVSR[31].

0    Cycle counter overflow on increment that changes PMCCNTR_EL0[31] from 1 to 0.
1    Cycle counter overflow on increment that changes PMCCNTR_EL0[63] from 1 to 0.

ARM deprecates use of PMCR_EL0.LC = 0.

In an AArch64-only implementation, this field is RES1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0    PMCCNTR_EL0, if enabled, counts when event counting is prohibited.
1    PMCCNTR_EL0 does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.

This bit is RW.

If EL3 is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0    Do not export events.
1    Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace macrocell, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to its defined reset value on Warm reset.
**D, bit [3]**

Clock divider. The possible values of this bit are:

- 0 when enabled, \texttt{PMCCNTR\_EL0} counts every clock cycle.
- 1 when enabled, \texttt{PMCCNTR\_EL0} counts once every 64 clock cycles.

This bit is RW.

If PMCR\_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of \texttt{PMCR.D = 1}.

In an AArch64-only implementation, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally \texttt{UNKNOWN}.

This field resets to its defined reset value on Warm reset.

**C, bit [2]**

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 no action.
- 1 reset \texttt{PMCCNTR\_EL0} to zero.

This bit is always RAZ.

Resetting \texttt{PMCCNTR\_EL0} does not clear the \texttt{PMCCNTR\_EL0} overflow bit to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally \texttt{UNKNOWN}.

This field resets to its defined reset value on Warm reset.

**P, bit [1]**

Event counter reset. This bit is WO. The effects of writing to this bit are:

- 0 no action.
- 1 reset all event counters accessible in the current EL, not including \texttt{PMCCNTR\_EL0}, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that \texttt{MDCR\_EL2.HPMN reserves for EL2 use}.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally \texttt{UNKNOWN}.

This field resets to its defined reset value on Warm reset.

**E, bit [0]**

Enable. The possible values of this bit are:

- 0 all counters, including \texttt{PMCCNTR\_EL0}, are disabled.
- 1 all counters are enabled by \texttt{PMCNTENSET\_EL0}.

This bit is RW.

If EL2 is implemented, this bit does not affect the operation of event counters that \texttt{MDCR\_EL2.HPMN reserves for EL2 use}.

When this register has an architecturally-defined reset value, this field resets to 0.

This field resets to its defined reset value on Warm reset.
Accessing the PMCR_EL0:

To access the PMCR_EL0:

MRS <Xt>, PMCR_EL0 ; Read PMCR_EL0 into Xt
MSR PMCR_EL0, <Xt> ; Write Xt to PMCR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1100</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.4.8 PMEVCNTR<\textit{n}>_EL0, Performance Monitors Event Count Registers, \( n = 0 - 30 \)

The PMEVCNTR<\textit{n}>_EL0 characteristics are:

**Purpose**

Holds event counter \( n \), which counts events, where \( n \) is 0 to 30.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

PMEVCNTR<\textit{n}>_EL0 can also be accessed by using PMXEVCNTR_EL0 with PMSELR_EL0.SEL set to \( n \).

If \(<n>\) is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<\textit{n}>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of PMUSERENR_EL0.EN is 1, if PMSELR_EL0.SEL is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

**Note**

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.ER==0, EL0 read accesses to this register are trapped to EL1.
- If PMUSERENR_EL0.EN==0, EL0 write accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMEVCNTR<\textit{n}>_EL0 is architecturally mapped to AArch32 System register PMEVCNTR<\textit{n}>.

AArch64 System register PMEVCNTR<\textit{n}>_EL0 is architecturally mapped to External register PMEVCNTR<\textit{n}>_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMEVCNTR<\textit{n}>_EL0 is a 32-bit register.
Field descriptions

The PMEVCNTR<\(n\)>_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event counter n</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

Accessing the PMEVCNTR<\(n\)>_EL0:

To access the PMEVCNTR<\(n\)>_EL0:

MRS <Xt>, PMEVCNTR<\(n\)>_EL0 ; Read PMEVCNTR<\(n\)>_EL0 into Xt, where n is in the range 0 to 30
MSR PMEVCNTR<\(n\)>_EL0, <Xt> ; Write Xt to PMEVCNTR<\(n\)>_EL0, where n is in the range 0 to 30

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>10:&lt;n&lt;4:3&gt;</td>
<td>&lt;n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>
D7.4.9 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

**Purpose**

Configures event counter n, where n is 0 to 30.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

PMEVTYPER<n>_EL0 can also be accessed by using PMXEVTPYPER_EL0 with PMSELR_EL0.SEL set to n.

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVTYPER<n>_EL0 are CONstrained UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of PMUSERENR_EL0.EN is 1, if PMSELR_EL0.SEL is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

**Note**

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMEVTYPER<n>_EL0 is architecturally mapped to AArch32 System register PMEVTYPER<n>.

AArch64 System register PMEVTYPER<n>_EL0 is architecturally mapped to External register PMEVTYPER<n>_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMEVTYPER<n>_EL0 is a 32-bit register.

**Field descriptions**

The PMEVTYPER<n>_EL0 bit assignments are:
**P, bit [31]**

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

0  Count events in EL1.
1  Do not count events in EL1.

**U, bit [30]**

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0  Count events in EL0.
1  Do not count events in EL0.

**NSK, bit [29]**

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted. Otherwise, events in Non-secure EL1 are not counted.

**NSU, bit [28]**

Non-secure User mode filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted. Otherwise, events in Non-secure EL0 are not counted.

**NSH, bit [27]**

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0  Do not count events in EL2.
1  Count events in EL2.

**M, bit [26]**

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Secure EL3 are counted. Otherwise, events in Secure EL3 are not counted.

**MT, bit [25]**

Multi-threading. If MPIDR_EL1.MT is set to 0, this bit is RES0. Otherwise valid values for this bit are:

0  Count events only on controlling PE.
1  Count events from any PE at the same level 0 affinity as this PE.
Note

Events from a different thread of a multi-threaded implementation are not attributable to the thread counting the event.

Bits [24:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<El0.

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back onevtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

Accessing the PMEVTYPER<El0:

To access the PMEVTYPER<El0:

MRS <Xt>, PMEVTYPER<El0> ; Read PMEVTYPER<El0> into Xt, where n is in the range 0 to 30
MSR PMEVTYPER<El0>, <Xt> ; Write Xt to PMEVTYPER<El0>, where n is in the range 0 to 30

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>11:n&lt;4:3&gt;</td>
<td>n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>
D7.4.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL1 and EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register PMINTENCLR_EL1 is architecturally mapped to AArch32 System register PMINTENCLR.

AArch64 System register PMINTENCLR_EL1 is architecturally mapped to External register PMINTENCLR_EL1.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31 30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;x&gt;, bit [x]</td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:

- 0: When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1: When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<n>_EL0.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.
Bits [30:N] are RAZ/WI.

Possible values are:

0  When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

1  When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<x>_EL0 interrupt request.

**Accessing the PMINTENCLR_EL1:**

To access the PMINTENCLR_EL1:

```
MRS <Xt>, PMINTENCLR_EL1 ; Read PMINTENCLR_EL1 into Xt
MSR PMINTENCLR_EL1, <Xt> ; Write Xt to PMINTENCLR_EL1
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

<td>1001</td>
<td>1110</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.4.11 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

**Purpose**

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<\textit{n}>_EL0. Reading the register shows which overflow interrupt requests are enabled.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If MDCR_EL2.TPM==1, Non-secure EL1 accesses to this register are trapped to EL2.

If MDCR_EL3.TPM==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

AArch64 System register PMINTENSET_EL1 is architecturally mapped to AArch32 System register PMINTENSET.

AArch64 System register PMINTENSET_EL1 is architecturally mapped to External register PMINTENSET_EL1.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMINTENSET_EL1 is a 32-bit register.

**Field descriptions**

The PMINTENSET_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31 30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;\textit{x}&gt;, bit [\textit{x}]</td>
</tr>
</tbody>
</table>

**C, bit [31]**

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

0  When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

1  When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

**P<\textit{x}>, bit [\textit{x}], for \textit{x} = 0 to 30**

Event counter overflow interrupt request enable bit for PMEVCNTR<\textit{x}>_EL0.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.
Bits [30:N] are RAZ/WI.
Possible values are:

0  When read, means that the PMEVCNTR<\text{x}>_EL0 event counter interrupt request is disabled. When written, has no effect.
1  When read, means that the PMEVCNTR<\text{x}>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<\text{x}>_EL0 interrupt request.

### Accessing the PMINTENSESET_EL1:

To access the PMINTENSESET_EL1:

MRS <Xt>, PMINTENSESET_EL1 ; Read PMINTENSESET_EL1 into Xt
MSR PMINTENSESET_EL1, <Xt> ; Write Xt to PMINTENSESET_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1001</td>
<td>1110</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.4.12 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVSCLR_EL0 characteristics are:

**Purpose**

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<\(x\)>. Writing to this register clears these bits.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMOVSCLR_EL0 is architecturally mapped to AArch32 System register PMOVSR.

AArch64 System register PMOVSCLR_EL0 is architecturally mapped to External register PMOVSCRL_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMOVSCLR_EL0 is a 32-bit register.

**Field descriptions**

The PMOVSCLR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31 30 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C, bit [31]</td>
</tr>
<tr>
<td>P&lt;(x)&gt;, bit [x]</td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR_EL0.LC is used to control from which bit of PMCCNTR_EL0 (bit 31 or bit 63) an overflow is detected.

P<\(x\)>, bit [x], for \(x = 0 \text{ to } 30\)

Event counter overflow clear bit for PMEVCNTR<\(x\)>.
Bits [30:N] are RAZ/WI.
When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Possible values of each bit are:

0  When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.
1  When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

**Accessing the PMOVSCLR_EL0:**

To access the PMOVSCLR_EL0:

MRS <Xt>, PMOVSCLR_EL0 ; Read PMOVSCLR_EL0 into Xt
MSR PMOVSCLR_EL0, <Xt> ; Write Xt to PMOVSCLR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1100</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.4.13 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

**Purpose**

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMOVSSET_EL0 is architecturally mapped to AArch32 System register PMOVSSET.

AArch64 System register PMOVSSET_EL0 is architecturally mapped to External register PMOVSSET_EL0.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMOVSSET_EL0 is a 32-bit register.

**Field descriptions**

The PMOVSSET_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C, bit [31]</td>
<td>PMCCNTR_EL0 overflow bit. Possible values are:</td>
</tr>
<tr>
<td>0</td>
<td>When read, means the cycle counter has not overflowed. When written, has no effect.</td>
</tr>
<tr>
<td>1</td>
<td>When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.</td>
</tr>
<tr>
<td>P&lt;x&gt;, bit [x], for x = 0 to 30</td>
<td>Event counter overflow set bit for PMEVCNTR&lt;x&gt;.</td>
</tr>
<tr>
<td>Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.</td>
<td></td>
</tr>
</tbody>
</table>
Possible values are:

0  When read, means that PMEVCNTR<\(x\)> has not overflowed. When written, has no effect.

1  When read, means that PMEVCNTR<\(x\)> has overflowed. When written, sets the PMEVCNTR<\(x\)> overflow bit to 1.

**Accessing the PMOVSSET_EL0:**

To access the PMOVSSET_EL0:

MRS \(<Xt>, \) PMOVSSET_EL0 \; Read PMOVSSET_EL0 into \(Xt\)

MSR PMOVSSET_EL0, \(<Xt>\) \; Write \(Xt\) to PMOVSSET_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1110</td>
<td>011</td>
</tr>
</tbody>
</table>
### D7.4.14 PMSELR_EL0, Performance Monitors Event Counter Selection Register

The PMSELR_EL0 characteristics are:

**Purpose**

Selects the current event counter PMEVCNTR<\(x\)> or the cycle counter, CCNT.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If \(MDCR_EL2.TPM==1\), Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If \(MDCR_EL3.TPM==1\), EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If \(PMUSERENR_EL0.EN==0\) and \(PMUSERENR_EL0.ER==0\), EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMSELR_EL0 is architecturally mapped to AArch32 System register PMSELR.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMSELR_EL0 is a 32-bit register.

**Field descriptions**

The PMSELR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>5–4</td>
<td>SEL</td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Reserved, RES0.

**SEL, bits [4:0]**

Selects event counter, PMEVCNTR<\(x\)>, where \(x\) is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPEPER_EL0 or PMXEVCNTR_EL0 occurs.

This field can take any value from 0 (000000) to (PMCR.N)-1, or 31 (0b11111).

When PMSELR_EL0.SEL is 0b11111 it selects the cycle counter and:

- A read of the PMXEVTYPEPER_EL0 returns the value of PMCCFILTR_EL0.
- A write of the PMXEVTYPEPER_EL0 writes to PMCCFILTR_EL0.
A read or write of PMXEVCNTR_EL0 has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:

- Access to PMXEVCNTR_EL0 is UNDEFINED.
- Access to PMXEVCNTR_EL0 behaves as a NOP.
- Access to PMXEVCNTR_EL0 behaves as if the register is RAZ/WI.
- Access to PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 is UNDEFINED.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as a NOP.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as if the register is RAZ/WI.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains an UNKNOWN value.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains 0b11111.

Accessing the PMSELR_EL0:

To access the PMSELR_EL0:

MRS <Xt>, PMSELR_EL0 ; Read PMSELR_EL0 into Xt
MSR PMSELR_EL0, <Xt> ; Write Xt to PMSELR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1100</td>
<td>101</td>
</tr>
</tbody>
</table>
### D7.4.15 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x00.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 write accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 write accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.SW==0, EL0 write accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMSWINC_EL0 is architecturally mapped to AArch32 System register PMSWINC.

AArch64 System register PMSWINC_EL0 is architecturally mapped to External register PMSWINC_EL0.

**Attributes**

PMSWINC_EL0 is a 32-bit register.

**Field descriptions**

The PMSWINC_EL0 bit assignments are:

\[
\begin{array}{cccccc}
31 & 30 & 0 & \\
 & & & \\
\end{array}
\]

**P<x>, bit [x]**

- **Bit [31]**
  
  Reserved, RES0.

- **P<x>, bit [x], for x = 0 to 30**

  Event counter software increment bit for PMEVCNTR<x>.

  Bits [30:N] are RAZ/WI.

  When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR.N.

  The effects of writing to this bit are:

  - 0: No action. The write to this bit is ignored.
If PMEVCNTR<\texttt{x}\texttt{>} is enabled and configured to count the software increment event, increments PMEVCNTR<\texttt{x}\texttt{>} by 1. If PMEVCNTR<\texttt{x}\texttt{>} is disabled, or not configured to count the software increment event, the write to this bit is ignored.

**Accessing the PMSWINC_EL0:**

To access the PMSWINC_EL0:

```
MSR PMSWINC_EL0, <Xt> ; Write Xt to PMSWINC_EL0
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th></th>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1100</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.4.16 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

Purpose

Enables or disables EL0 access to the Performance Monitors.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.

If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.

Configurations

AArch64 System register PMUSERENR_EL0 is architecturally mapped to AArch32 System register PMUSERENR.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

PMUSERENR_EL0 is a 32-bit register.

Field descriptions

The PMUSERENR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

ER, bit [3]

Event counter read trap control:

- EL0 using AArch64: EL0 reads of the PMXEVCNTR_EL0 and PMEVCTR<n>_EL0, and EL0 read/write accesses to the PMSELR_EL0, are trapped to EL1 if PMUSERENR_EL0.EN is also 0.
- EL0 using AArch32: EL0 reads of the PMXEVCNTR and PMEVCTR<n>, and EL0 read/write accesses to the PMSELR, are trapped to EL1 if PMUSERENR_EL0.EN is also 0.
EL0 using AArch64: EL0 reads of the PMXEVCNTR_EL0 and PMEVCNTR<n>_EL0, and EL0 read/write accesses to the PMSELR_EL0, are not trapped to EL1.

EL0 using AArch32: EL0 reads of the PMXEVCNTR and PMEVCNTR<n>, and EL0 read/write accesses to the PMSELR, are not trapped to EL1.

CR, bit [2]

Cycle counter read trap control:

0  EL0 using AArch64: EL0 read accesses to the PMCCNTR_EL0 are trapped to EL1 if PMUSERENR_EL0.EN is also 0.
   EL0 using AArch32: EL0 read accesses to the PMCCNTR are trapped to EL1 if PMUSERENR_EL0.EN is also 0.

1  EL0 using AArch64: EL0 read accesses to the PMCCNTR_EL0 are not trapped to EL1.
   EL0 using AArch32: EL0 read accesses to the PMCCNTR are not trapped to EL1.

SW, bit [1]

Software Increment write trap control:

0  EL0 using AArch64: EL0 writes to the PMSWINC_EL0 are trapped to EL1 if PMUSERENR_EL0.EN is also 0.
   EL0 using AArch32: EL0 writes to the PMSWINC are trapped to EL1 if PMUSERENR_EL0.EN is also 0.

1  EL0 using AArch64: EL0 writes to the PMSWINC_EL0 are not trapped to EL1.
   EL0 using AArch32: EL0 writes to the PMSWINC are not trapped to EL1.

EN, bit [0]

Traps EL0 accesses to the Performance Monitors registers to EL1, from both Execution states:

0  EL0 accesses to the Performance Monitors registers are trapped to EL1.

1  EL0 accesses to the Performance Monitors registers are not trapped to EL1. Software can access all PMU registers at EL0.

--- Note ---

- The PMUSERENR_EL0 and PMUSERENR registers are always RO at EL0 and not trapped by this bit.
- EL0 cannot read or write PMINTENSET_EL1 and PMINTENCLR_EL1, or PMINTENSET and PMINTENCLR.

Accessing the PMUSERENR_EL0:

To access the PMUSERENR_EL0:

MRS <Xt>, PMUSERENR_EL0 ; Read PMUSERENR_EL0 into Xt
MSR PMUSERENR_EL0, <Xt> ; Write Xt to PMUSERENR_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1110</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.4.17 PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVCNTR_EL0 characteristics are:

**Purpose**
Reads or writes the value of the selected event counter, PMEVCNTR<n>_EL0. PMSEL_EL0.SEL determines which event counter is selected.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If PMSEL_EL0.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSEL_EL0.SEL has an UNKNOWN value less than the number of accessible counters at the current Exception level and Security state.
- Accesses to the register behave as if PMSEL_EL0.SEL is 31.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of PMUSERENR_EL0.EN is 1, if PMSEL_EL0.SEL is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

**Note**
In an implementation that includes EL2, in Non-secure state at EL0 and EL1, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.ER==0, EL0 read accesses to this register are trapped to EL1.
- If PMUSERENR_EL0.EN==0, EL0 write accesses to this register are trapped to EL1.

**Configurations**
AArch64 System register PMXEVCNTR_EL0 is architecturally mapped to AArch32 System register PMXEVCNTR.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**
PMXEVCNTR_EL0 is a 32-bit register.
Field descriptions

The PMXEVCNTR_EL0 bit assignments are:

```
+-------------------+-----------+-----+-----+-----+
| 31                | 0         |     |     |     |
| PMEVCNTR<x>       |           |     |     |     |
+-------------------+-----------+-----+-----+-----+
```

PMEVCNTR<x>, bits [31:0]

Value of the selected event counter, PMEVCNTR<x>_EL0, where x is the value stored in PMSELR_EL0.SEL.

Accessing the PMXEVCNTR_EL0:

To access the PMXEVCNTR_EL0:

```
MRS <Xt>, PMXEVCNTR_EL0 ; Read PMXEVCNTR_EL0 into Xt
MSR PMXEVCNTR_EL0, <Xt> ; Write Xt to PMXEVCNTR_EL0
```

Register access is encoded as follows:

```
<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1101</td>
<td>010</td>
</tr>
</tbody>
</table>
```
D7.4.18 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

**Purpose**

When PMSELR_EL0.SEL selects an event counter, this accesses a PMEVTYPER<\textit{<n>}>_EL0 register. When PMSELR_EL0.SEL selects the cycle counter, this accesses PMCCFILTR_EL0.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If PMSELR_EL0.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVTYPER_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a \texttt{NOP}.
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_EL0.SEL is 31.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of PMUSERENR_EL0.EN is 1, if PMSELR_EL0.SEL is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

**Note**

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see \textit{Synchronous exception prioritization} on page D1-1546. Subject to the prioritization rules:

- If MDCR_EL2.TPM==1, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If MDCR_EL3.TPM==1, EL0, EL1, and EL2 accesses to this register are trapped to EL3.
- If PMUSERENR_EL0.EN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register PMXEVTYPER_EL0 is architecturally mapped to AArch32 System register PMXEVTYPER.

On Warm reset, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

PMXEVTYPER_EL0 is a 32-bit register.

**Field descriptions**

The PMXEVTYPER_EL0 bit assignments are:
Bits [31:0]

Event type register or PMCCFILTR_EL0.

When PMSELR_EL0.SEL == 31, this register accesses PMCCFILTR_EL0.

Otherwise, this register accesses PMEVTYPER<n>_EL0 where n is the value in PMSELR_EL0.SEL.

Accessing the PMXEVTYPER_EL0:

To access the PMXEVTYPER_EL0:

MRS <Xt>, PMXEVTYPER_EL0 ; Read PMXEVTYPER_EL0 into Xt
MSR PMXEVTYPER_EL0, <Xt> ; Write Xt to PMXEVTYPER_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1001</td>
<td>1101</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.5 Generic Timer registers

This section lists the Generic Timer registers in AArch64.
**D7.5.1 CNTFRQ_EL0, Counter-timer Frequency register**

The CNTFRQ_EL0 characteristics are:

**Purpose**

Holds the clock frequency of the system counter.

**Usage constraints**

If EL1 is the highest exception level implemented and is using AArch64, this register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL2 is the highest exception level implemented and is using AArch64, this register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1</th>
<th>EL2 (NS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, this register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RW</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

Can only be written at the highest Exception level implemented. For example, if EL3 is the highest implemented Exception level, CNTFRQ_EL0 can only be written at EL3.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If CNTKCTL_EL1.EL0PCTEN==0, and CNTKCTL_EL1.EL0VCTEN==0, EL0 read accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register CNTFRQ_EL0 is architecturally mapped to AArch32 System register CNTFRQ.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTFRQ_EL0 is a 32-bit register.

**Field descriptions**

The CNTFRQ_EL0 bit assignments are:

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
</tbody>
</table>

Clock frequency
Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

**Accessing the CNTFRQ_EL0:**

To access the CNTFRQ_EL0:

MRS <Xt>, CNTFRQ_EL0  ; Read CNTFRQ_EL0 into Xt
MSR CNTFRQ_EL0, <Xt>  ; Write Xt to CNTFRQ_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>0000</td>
<td>00</td>
</tr>
</tbody>
</table>
D7.5.2 CNTHCTL_EL2, Counter-timer Hypervisor Control register

The CNTHCTL_EL2 characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 to the physical counter and the Non-secure EL1 physical timer.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTHCTL_EL2 is architecturally mapped to AArch32 System register CNTHCTL.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

CNTHCTL_EL2 is a 32-bit register.

Field descriptions

The CNTHCTL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EVNTI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT_EL0 or CNTVCT_EL0) is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT_EL0 or CNTVCT_EL0) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0  A 0 to 1 transition of the trigger bit triggers an event.
1  A 1 to 0 transition of the trigger bit triggers an event.
EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0   Disables the event stream.
1   Enables the event stream.

EL1PCEN, bit [1]

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to EL2.

0   From AArch64 state: Non-secure EL0 and EL1 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 are trapped to EL2.
    From AArch32 state: Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to EL2.
1   From AArch64 state: Non-secure EL0 and EL1 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 are not trapped to EL2.
    From AArch32 state: Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are not trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

EL1PCTEN, bit [0]

Traps Non-secure EL0 and EL1 accesses to the physical counter register to EL2.

0   From AArch64 state: Non-secure EL0 and EL1 accesses to the CNTPCT_EL0 are trapped to EL2.
    From AArch32 state: Non-secure EL0 and EL1 accesses to the CNTPCT are trapped to EL2.
1   From AArch64 state: Non-secure EL0 and EL1 accesses to the CNTPCT_EL0 are not trapped to EL2.
    From AArch32 state: Non-secure EL0 and EL1 accesses to the CNTPCT are not trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

Accessing the CNTHCTL_EL2:

To access the CNTHCTL_EL2:

MRS <Xt>, CNTHCTL_EL2 ; Read CNTHCTL_EL2 into Xt
MSR CNTHCTL_EL2, <Xt> ; Write Xt to CNTHCTL_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1110</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.5.3  CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register

The CNTHP_CTL_EL2 characteristics are:

**Purpose**

Control register for the EL2 physical timer.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register CNTHP_CTL_EL2 is architecturally mapped to AArch32 System register CNTHP_CTL.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTHP_CTL_EL2 is a 32-bit register.

**Field descriptions**

The CNTHP_CTL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>0</td>
<td>ISTATUS</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is asserted:

- 0 Timer condition is not asserted.
- 1 Timer condition is asserted.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers on page D6-1897* and *Operation of the TimerValue views of the timers on page D6-1898*.

This bit is read-only.
IMASK, bit [1]
Timer output signal mask bit. Permitted values are:
0  Timer output signal is not masked.
1  Timer output signal is masked.
For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]
Enables the timer. Permitted values are:
0  Timer disabled.
1  Timer enabled.
Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHP_TVVAL_EL2 continues to count down.

Note
Disabling the output signal might be a power-saving option.

Accessing the CNTHP_CTL_EL2:
To access the CNTHP_CTL_EL2:

MRS <Xt>, CNTHP_CTL_EL2 ; Read CNTHP_CTL_EL2 into Xt
MSR CNTHP_CTL_EL2, <Xt> ; Write Xt to CNTHP_CTL_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1110</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
D.7.5.4 CNTHP_CVAL_EL2, Counter-timer Hypervisor Physical Timer CompareValue register

The CNTHP_CVAL_EL2 characteristics are:

**Purpose**
Holds the compare value for the EL2 physical timer.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**
There are no traps or enables affecting this register.

**Configurations**
AArch64 System register CNTHP_CVAL_EL2 is architecturally mapped to AArch32 System register CNTHP_CVAL.
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**
CNTHP_CVAL_EL2 is a 64-bit register.

**Field descriptions**
The CNTHP_CVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>EL2 physical timer compare value</th>
</tr>
</thead>
</table>

**Accessing the CNTHP_CVAL_EL2:**
To access the CNTHP_CVAL_EL2:

MRS <Xt>, CNTHP_CVAL_EL2 ; Read CNTHP_CVAL_EL2 into Xt
MSR CNTHP_CVAL_EL2, <Xt> ; Write Xt to CNTHP_CVAL_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1110</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.5 CNTHP_TVAL_EL2, Counter-timer Hypervisor Physical Timer TimerValue register

The CNTHP_TVAL_EL2 characteristics are:

**Purpose**

Holds the timer value for the EL2 physical timer.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Where the value of CNTHP_CTL_EL2.ENABLE is 0:

- A write to CNTHP_TVAL_EL2 updates the register
- The value held in CNTHP_TVAL_EL2 continues to decrement
- A read of CNTHP_TVAL_EL2 returns an UNKNOWN value.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register CNTHP_TVAL_EL2 is architecturally mapped to AArch32 System register CNTHP_TVAL.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTHP_TVAL_EL2 is a 32-bit register.

**Field descriptions**

The CNTHP_TVAL_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL2 physical timer value</td>
</tr>
</tbody>
</table>

**Accessing the CNTHP_TVAL_EL2:**

To access the CNTHP_TVAL_EL2:

MRS <Xt>, CNTHP_TVAL_EL2 ; Read CNTHP_TVAL_EL2 into Xt
MSR CNTHP_TVAL_EL2, <Xt> ; Write Xt to CNTHP_TVAL_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1110</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.5.6  CNTKCTL_EL1, Counter-timer Kernel Control register

The CNTKCTL_EL1 characteristics are:

**Purpose**

Controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register CNTKCTL_EL1 is architecturally mapped to AArch32 System register CNTKCTL.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTKCTL_EL1 is a 32-bit register.

**Field descriptions**

The CNTKCTL_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>10</td>
<td>EVNTI</td>
</tr>
<tr>
<td>9</td>
<td>EL0PCTEN</td>
</tr>
<tr>
<td>8</td>
<td>EL0VCTEN</td>
</tr>
<tr>
<td>7</td>
<td>EVNTEN</td>
</tr>
<tr>
<td>6</td>
<td>EVNTDIR</td>
</tr>
<tr>
<td>5</td>
<td>EL0VTEN</td>
</tr>
<tr>
<td>4</td>
<td>EL0PTEN</td>
</tr>
</tbody>
</table>

**Bits [31:10]**

Reserved, RES0.

**EL0PTEN, bit [9]**

Traps EL0 accesses to the physical timer registers to EL1.

0  

EL0 using AArch64: EL0 accesses to the `CNTP_CTL_EL0`, `CNTP_CVAL_EL0`, and `CNTP_TVAL_EL0` registers are trapped to EL1.

EL0 using AArch32: EL0 accesses to the `CNTP_CTL`, `CNTP_CVAL`, and `CNTP_TVAL` registers are trapped to EL1.

1  

EL0 using AArch64: EL0 accesses to the `CNTP_CTL_EL0`, `CNTP_CVAL_EL0`, and `CNTP_TVVAL_EL0` registers are not trapped to EL1.

EL0 using AArch32: EL0 accesses to the `CNTP_CTL`, `CNTP_CVAL`, and `CNTP_TVAL` registers are not trapped to EL1.
**EL0VTEN, bit [8]**

Traps EL0 accesses to the virtual timer registers to EL1.

0  
EL0 using AArch64: EL0 accesses to the CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 registers are trapped to EL1.

EL0 using AArch32: EL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are trapped to EL1.

1  
EL0 using AArch64: EL0 accesses to the CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 registers are not trapped to EL1.

EL0 using AArch32: EL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are not trapped to EL1.

**EVNTI, bits [7:4]**

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT_EL0 or CNTVCT_EL0) is the trigger for the event stream generated from that counter, when that stream is enabled.

**EVNTDIR, bit [3]**

Controls which transition of the counter register (CNTPCT_EL0 or CNTVCT_EL0) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0  
A 0 to 1 transition of the trigger bit triggers an event.

1  
A 1 to 0 transition of the trigger bit triggers an event.

**EVNTEN, bit [2]**

Enables the generation of an event stream from the corresponding counter:

0  
Disables the event stream.

1  
Enables the event stream.

**EL0VCTEN, bit [1]**

Traps EL0 accesses to the frequency register and virtual counter register to Undefined mode.

0  
EL0 using AArch64: EL0 accesses to the CNTVCT_EL0 are trapped to EL1.

EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL1, if CNTKCTL_EL1.EL0PCTEN is also 0.

EL0 using AArch32: EL0 accesses to the CNTVCT are trapped to EL1.

EL0 using AArch32: EL0 accesses to the CNTFRQ register are trapped to EL1, if CNTKCTL_EL1.EL0VCTEN is also 0.

1  
EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 and CNTVCT_EL0 are not trapped to EL1.

EL0 using AArch32: EL0 accesses to the CNTFRQ and CNTVCT are not trapped to EL1.

**EL0PCTEN, bit [0]**

Traps EL0 accesses to the frequency register and physical counter register to EL1.

0  
EL0 using AArch64: EL0 accesses to the CNTPCT_EL0 are trapped to EL1.

EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL1, if CNTKCTL_EL1.EL0VCTEN is also 0.

EL0 using AArch32: EL0 accesses to the CNTPCT are trapped to EL1.

EL0 using AArch32: EL0 accesses to the CNTFRQ and register are trapped to EL1, if CNTKCTL_EL1.EL0VCTEN is also 0.

1  
EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 and CNTPCT_EL0 are not trapped to EL1.

EL0 using AArch32: EL0 accesses to the CNTFRQ and CNTPCT are not trapped to EL1.
Accessing the CNTKCTL_EL1:

To access the CNTKCTL_EL1:

MRS <Xt>, CNTKCTL_EL1 ; Read CNTKCTL_EL1 into Xt
MSR CNTKCTL_EL1, <Xt> ; Write Xt to CNTKCTL_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1110</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.5.7 CNTP_CTL_EL0, Counter-timer Physical Timer Control register

The CNTP_CTL_EL0 characteristics are:

**Purpose**

Control register for the EL1 physical timer.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If CNTHCTL_EL2.EL1PCEN==0, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.

If CNTKCTL_EL1.EL0PTEN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register CNTP_CTL_EL0 is architecturally mapped to AArch32 System register CNTP_CTL.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTP_CTL_EL0 is a 32-bit register.

**Field descriptions**

The CNTP_CTL_EL0 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    | RES0 | ENABLE | IMASK | ISTATUS |

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is asserted:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer condition is not asserted.</td>
</tr>
<tr>
<td>1</td>
<td>Timer condition is asserted.</td>
</tr>
</tbody>
</table>

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers* on page D6-1897 and *Operation of the TimerValue views of the timers* on page D6-1898.
This bit is read-only.

**IMASK, bit [1]**

Timer output signal mask bit. Permitted values are:

- **0**: Timer output signal is not masked.
- **1**: Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

- **0**: Timer disabled.
- **1**: Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TV0 continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

--- Accessing the CNTP_CTL_EL0: ---

To access the CNTP_CTL_EL0:

```
MRS <Xt>, CNTP_CTL_EL0; Read CNTP_CTL_EL0 into Xt
MSR CNTP_CTL_EL0, <Xt>; Write Xt to CNTP_CTL_EL0
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>

</table>
D7.5.8 CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL_EL0 characteristics are:

**Purpose**

Holds the compare value for the EL1 physical timer.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If CNTHCTL_EL2.EL1PCEN==0, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.

If CNTKCTL_EL1.EL0PTEN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register CNTP_CVAL_EL0 is architecturally mapped to AArch32 System register CNTP_CVAL.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTP_CVAL_EL0 is a 64-bit register.

**Field descriptions**

The CNTP_CVAL_EL0 bit assignments are:

63 0

EL1 physical timer compare value

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>EL1 physical timer compare value</th>
</tr>
</thead>
</table>

**Accessing the CNTP_CVAL_EL0:**

To access the CNTP_CVAL_EL0:

MRS <Xt>, CNTP_CVAL_EL0 ; Read CNTP_CVAL_EL0 into Xt
MSR CNTP_CVAL_EL0, <Xt> ; Write Xt to CNTP_CVAL_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.5.9  **CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register**

The CNTP_TVAL_EL0 characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Where the value of CNTP_CTL_EL0.ENABLE is 0:

- A write to CNTP_TVAL_EL0 updates the register
- The value held in CNTP_TVAL_EL0 continues to decrement
- A read of CNTP_TVAL_EL0 returns an UNKNOWN value.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If CNTHCTL_EL2.EL1PCEN==0, Non-secure EL0 and EL1 accesses to this register are trapped to EL2.
- If CNTKCTL_EL1.EL0PTEN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register CNTP_TVAL_EL0 is architecturally mapped to AArch32 System register CNTP_TVAL.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTP_TVAL_EL0 is a 32-bit register.

**Field descriptions**

The CNTP_TVAL_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL1 physical timer value</td>
</tr>
</tbody>
</table>

**Accessing the CNTP_TVAL_EL0:**

To access the CNTP_TVAL_EL0:

MRS <Xt>, CNTP_TVAL_EL0 ; Read CNTP_TVAL_EL0 into Xt
MSR CNTP_TVAL_EL0, <Xt> ; Write Xt to CNTP_TVAL_EL0
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>

<td>11</td>
<td>011</td>
<td>1110</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.5.10   CNTPCT_EL0, Counter-timer Physical Count register

The CNTPCT_EL0 characteristics are:

**Purpose**

Holds the 64-bit physical count value.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If CNTHCTL_EL2.EL1PCTEN==0, Non-secure EL0 and EL1 read accesses to this register are trapped to EL2.

If CNTKCTL_EL1.EL0PCTEN==0, EL0 read accesses to this register are trapped to EL1.

**Configurations**

AArch64 System register CNTPCT_EL0 is architecturally mapped to AArch32 System register CNTPCT.

**Attributes**

CNTPCT_EL0 is a 64-bit register.

**Field descriptions**

The CNTPCT_EL0 bit assignments are:

```
   63 0

   Physical count value

   Bits [63:0]

   Physical count value.
```

**Accessing the CNTPCT_EL0:**

To access the CNTPCT_EL0:

```
MRS <Xt>, CNTPCT_EL0 ; Read CNTPCT_EL0 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>0000</td>
<td>001</td>

</tbody>
</table>

D7.5.11  CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register

The CNTPS_CTL_EL1 characteristics are:

Purpose
Control register for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If SCR_EL3.ST==0, Secure EL1 accesses to this register are trapped to EL3.

Configurations
RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes
CNTPS_CTL_EL1 is a 32-bit register.

Field descriptions
The CNTPS_CTL_EL1 bit assignments are:

| 31 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    | RES0|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits [31:3]
Reserved, RES0.

ISTATUS, bit [2]
The status of the timer. This bit indicates whether the timer condition is asserted:

| 0 | Timer condition is not asserted. |
| 1 | Timer condition is asserted.   |

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see Operation of the CompareValue views of the timers on page D6-1897 and Operation of the TimerValue views of the timers on page D6-1898.

This bit is read-only.
IMASK, bit [1]

Timer output signal mask bit. Permitted values are:

0    Timer output signal is not masked.
1    Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0    Timer disabled.
1    Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTPS_TVAL_EL1 continues to count down.

Note
Disabling the output signal might be a power-saving option.

Accessing the CNTPS_CTL_EL1:

To access the CNTPS_CTL_EL1:

MRS <Xt>, CNTPS_CTL_EL1 ; Read CNTPS_CTL_EL1 into Xt
MSR CNTPS_CTL_EL1, <Xt> ; Write Xt to CNTPS_CTL_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>111</td>
<td>1110</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.5.12 CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register

The CNTPS_CVAL_EL1 characteristics are:

**Purpose**

Holds the compare value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If SCR_EL3.ST==0, Secure EL1 accesses to this register are trapped to EL3.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTPS_CVAL_EL1 is a 64-bit register.

**Field descriptions**

The CNTPS_CVAL_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Secure physical timer compare value</th>
</tr>
</thead>
</table>

**Accessing the CNTPS_CVAL_EL1:**

To access the CNTPS_CVAL_EL1:

MRS <Xt>, CNTPS_CVAL_EL1 ; Read CNTPS_CVAL_EL1 into Xt
MSR CNTPS_CVAL_EL1, <Xt> ; Write Xt to CNTPS_CVAL_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>111</td>
<td>1110</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.5.13  **CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register**

The CNTPS_TVAL_EL1 characteristics are:

**Purpose**

Holds the timer value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Where the value of CNTPS_CTL_EL1.ENABLE is 0:

- A write to CNTPS_TVAL_EL1 updates the register
- The value held in CNTPS_TVAL_EL1 continues to decrement
- A read of CNTPS_TVAL_EL1 returns an UNKNOWN value.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If SCR_EL3.ST==0, Secure EL1 accesses to this register are trapped to EL3.

**Configurations**

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTPS_TVAL_EL1 is a 32-bit register.

**Field descriptions**

The CNTPS_TVAL_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Secure physical timer value</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Secure physical timer value.

**Accessing the CNTPS_TVAL_EL1:**

To access the CNTPS_TVAL_EL1:

MRS <Xt>, CNTPS_TVAL_EL1 ; Read CNTPS_TVAL_EL1 into Xt
MSR CNTPS_TVAL_EL1, <Xt> ; Write Xt to CNTPS_TVAL_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>

<td>1110</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.5.14  CNTV_CTL_EL0, Counter-timer Virtual Timer Control register

The CNTV_CTL_EL0 characteristics are:

Purpose

Control register for the virtual timer.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If CNTKCTL_EL1.EL0VTEN==0, EL0 accesses to this register are trapped to EL1.

Configurations

AArch64 System register CNTV_CTL_EL0 is architecturally mapped to AArch32 System register CNTV_CTL.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

Attributes

CNTV_CTL_EL0 is a 32-bit register.

Field descriptions

The CNTV_CTL_EL0 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 |

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is asserted:

0  Timer condition is not asserted.
1  Timer condition is asserted.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see Operation of the CompareValue views of the timers on page D6-1897 and Operation of the TimerValue views of the timers on page D6-1898.

This bit is read-only.
**IMASK, bit [1]**

Timer output signal mask bit. Permitted values are:

0  Timer output signal is not masked.
1  Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

0  Timer disabled.
1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVVAL_EL0 continues to count down.

**Note**

Disabling the output signal might be a power-saving option.

**Accessing the CNTV_CTL_EL0:**

To access the CNTV_CTL_EL0:

MRS <Xt>, CNTV_CTL_EL0 ; Read CNTV_CTL_EL0 into Xt
MSR CNTV_CTL_EL0, <Xt> ; Write Xt to CNTV_CTL_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>

</tbody>
</table>
D7.5.15  CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL_EL0 characteristics are:

**Purpose**
Holds the compare value for the virtual timer.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:
If CNTKCTL_EL1.EL0VTEN==0, EL0 accesses to this register are trapped to EL1.

**Configurations**
AArch64 System register CNTV_CVAL_EL0 is architecturally mapped to AArch32 System register CNTV_CVAL.

**Attributes**
CNTV_CVAL_EL0 is a 64-bit register.

**Field descriptions**
The CNTV_CVAL_EL0 bit assignments are:

![Virtual timer compare value diagram]

Bits [63:0]
Virtual timer compare value.

**Accessing the CNTV_CVAL_EL0:**
To access the CNTV_CVAL_EL0:

MRS <Xt>, CNTV_CVAL_EL0 ; Read CNTV_CVAL_EL0 into Xt
MSR CNTV_CVAL_EL0, <Xt> ; Write Xt to CNTV_CVAL_EL0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>

<td>011</td>
<td>1110</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
### D7.5.17 CNTVCT_EL0, Counter-timer Virtual Count register

The CNTVCT_EL0 characteristics are:

**Purpose**
Holds the 64-bit virtual count value.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If CNTKCTL_EL1.EL0VCTEN==0, EL0 read accesses to this register are trapped to EL1.

**Configurations**
AArch64 System register CNTVCT_EL0 is architecturally mapped to AArch32 System register CNTVCT.

**Attributes**
CNTVCT_EL0 is a 64-bit register.

**Field descriptions**
The CNTVCT_EL0 bit assignments are:

```
63 62 61 60 59 58 57 56 55 54 53 52 51 50 49 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Virtual count value
```

**Bits [63:0]**
Virtual count value.

**Accessing the CNTVCT_EL0:**
To access the CNTVCT_EL0:

```
MRS <Xt>, CNTVCT_EL0 ; Read CNTVCT_EL0 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>011</td>
<td>1110</td>
<td>0000</td>
<td>010</td>

<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register CNTVOFF_EL2 is architecturally mapped to AArch32 System register CNTVOFF.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN.

**Attributes**

CNTVOFF_EL2 is a 64-bit register.

**Field descriptions**

The CNTVOFF_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual offset</th>
</tr>
</thead>
</table>

**Accessing the CNTVOFF_EL2:**

To access the CNTVOFF_EL2:

MRS <Xt>, CNTVOFF_EL2 ; Read CNTVOFF_EL2 into Xt
MSR CNTVOFF_EL2, <Xt> ; Write Xt to CNTVOFF_EL2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1110</td>
<td>0000</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.6 About the Generic Interrupt Controller (GIC) System registers

The ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 defines the full set of Generic Interrupt Controller (GIC) registers. These comprise:

- Memory-mapped registers, with register names prefixed by one of the following:
  - GICC, indicating a memory-mapped CPU interface register.
  - GICD, indicating a Distributor register.
  - GICH, indicating a memory-mapped virtual interface control register, typically accessed by a hypervisor.
  - GICR, indicating a Redistributor register.
  - GICV, indicating a virtual CPU interface register.
  - GITS, indicating an ITS register.

- System registers, with register names prefixed by one of the following:
  - ICC, indicating a GIC CPU interface System register.
  - ICH, indicating a virtual interface control System register.

When implemented, the System registers defined by the GIC Architecture Specification form part of an ARM processor implementation, and therefore the definitions of these registers are duplicated in this Manual.

--- Note ---

The GIC System register descriptions published in the GIC Architecture Specification and those published in this Manual are derived from a single source. Document release dates indicate when the descriptions were imported from that source.

---

Some of the GIC System register descriptions include references to GIC memory-mapped registers. See the GIC Architecture Specification for more information about those registers.

The following sections describe the GIC System registers:
- Generic Interrupt Controller CPU interface System registers on page D7-2293.
- Generic Interrupt Controller Virtual interface control System registers on page D7-2349.
D7.7 Generic Interrupt Controller CPU interface System registers

See About the Generic Interrupt Controller (GIC) System registers on page D7-2292 for general information about the complete set of GIC registers, and about the subset of those registers that are described in this Manual.

This section describes the AArch64 GIC CPU interface System registers.
D7.7.1 ICC_AP0R<n>_EL1, Interrupt Controller Active Priorities Group 0 Registers, n = 0 - 3

The ICC_AP0R<n>_EL1 characteristics are:

**Purpose**

Provides information about Group 0 active priorities.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Writing to these registers with any value other than the last read value of the register (or 0x00000000 when no interrupts are active) might cause the interrupt prioritization system to malfunction, causing:

- Interrupts that should pre-empt execution to not pre-empt execution.
- Interrupts that should not pre-empt execution.

ICC_AP0R1_EL1 is only implemented in implementations that support 6 or more bits of priority. ICC_AP0R2_EL1 and ICC_AP0R3_EL1 are only implemented in implementations that support 7 bits of priority. If an implementation that supports fewer bits of priority attempts to access these registers, it generates an Undefined Instruction exception.

Writing to the active priority registers in any order other than the following order might cause the interrupt prioritization system to malfunction:

- ICC_AP0R<n>_EL1.
- Secure ICC_AP1R<n>_EL1.
- Non-secure ICC_AP1R<n>_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_HCR_EL2.TALL0==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_AP0R<n>_EL1 is architecturally mapped to AArch32 System register ICC_AP0R<n>.

**Attributes**

ICC_AP0R<n>_EL1 is a 32-bit register.

**Field descriptions**

The ICC_AP0R<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>
IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the ICC_AP0R<n>_EL1:**

To access the ICC_AP0R<n>_EL1:

MRS <Xt>, ICC_AP0R<n>_EL1 ; Read ICC_AP0R<n>_EL1 into Xt, where n is in the range 0 to 3
MSR ICC_AP0R<n>_EL1, <Xt> ; Write Xt to ICC_AP0R<n>_EL1, where n is in the range 0 to 3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>1:n&lt;1:0&gt;</td>
</tr>
</tbody>
</table>
D7.7.2 ICC_AP1R<n>_EL1, Interrupt Controller Active Priorities Group 1 Registers, n = 0 - 3

The ICC_AP1R<n>_EL1 characteristics are:

**Purpose**

Provides information about Group 1 active priorities.

**Usage constraints**

ICC_AP1R<n>_EL1(S) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

ICC_AP1R<n>_EL1(NS) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Writing to these registers with any value other than the last read value of the register (or 0x00000000 when no interrupts are active) might cause the interrupt prioritization system to malfunction, causing:

- Interrupts that should pre-empt execution to not pre-empt execution.
- Interrupts that should not pre-empt execution to pre-empt execution.

ICC_AP1R1_EL1 is only implemented in implementations that support 6 or more bits of priority. ICC_AP1R2_EL1 and ICC_AP1R3_EL1 are only implemented in implementations that support 7 bits of priority. If an implementation that supports fewer bits of priority attempts to access these registers, it generates an Undefined Instruction exception.

Writing to the active priority registers in any order other than the following order might cause the interrupt prioritization system to malfunction:

- ICC_AP0R<n>_EL1.
- Secure ICC_AP1R<n>_EL1.
- Non-secure ICC_AP1R<n>_EL1.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If ICC_HCR_EL2.TALL1==1, Non-secure EL1 accesses to this register are trapped to EL2.
If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

There are separate Secure and Non-secure instances of this register.

AArch64 System register ICC_AP1R<n>_EL1(S) is architecturally mapped to AArch32 System register ICC_AP1R<n>_EL1(S).

AArch64 System register ICC_AP1R<n>_EL1(NS) is architecturally mapped to AArch32 System register ICC_AP1R<n>_EL1(NS).

The contents of these registers are IMPLEMENTATION DEFINED with the one architectural requirement that the value 0x00000000 is consistent with no interrupts being active.
Attributes

ICC_AP1R<n>_EL1 is a 32-bit register.

Field descriptions

The ICC_AP1R<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the ICC_AP1R<n>_EL1:

To access the ICC_AP1R<n>_EL1:

MRS <Xt>, ICC_AP1R<n>_EL1; Read ICC_AP1R<n>_EL1 into Xt, where n is in the range 0 to 3
MSR ICC_AP1R<n>_EL1, <Xt>; Write Xt to ICC_AP1R<n>_EL1, where n is in the range 0 to 3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1001</td>
<td>0:n&lt;1:0&gt;</td>
</tr>
</tbody>
</table>
D7.7.3 ICC_ASGI1R_EL1, Interrupt Controller Alias Software Generated Interrupt Group 1 Register

The ICC_ASGI1R_EL1 characteristics are:

Purpose
Generates Group 1 SGIs for the Security state that is not the current Security state.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:
- If ICH_HCR_EL2.TC==1, Non-secure EL1 write accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 write accesses to this register are UNDEFINED.

Configurations
AArch64 System register ICC_ASGI1R_EL1 performs the same function as AArch32 System operation ICC_ASGI1R.

Attributes
ICC_ASGI1R_EL1 is a 64-bit register.

Field descriptions
The ICC_ASGI1R_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:56</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>55:48</td>
<td>Affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated. If the IRM bit is 1, this field is RES0.</td>
</tr>
<tr>
<td>47:41</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>40</td>
<td>Interrupt Routing Mode. Determines how the generated interrupts should be distributed to PEs. Possible values are: 0 Interrupts routed to the PEs specified by Aff3.Aff2.Aff1.&lt;target list&gt;.</td>
</tr>
</tbody>
</table>
1. Interrupts routed to all PEs in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.
If the IRM bit is 1, this field is RES0.

**Bits [31:28]**

Reserved, RES0.

**INTID, bits [27:24]**

The interrupt ID of the SGI.

**Aff1, bits [23:16]**

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.
If the IRM bit is 1, this field is RES0.

**TargetList, bits [15:0]**

Target List. The set of PEs for which SGI interrupts will be generated. Each bit corresponds to the PE within a cluster with an Affinity 0 value equal to the bit number.
If a bit is 1 and the bit does not correspond to a valid target PE, the bit must be ignored by the Distributor. It is IMPLEMENTATION DEFINED whether, in such cases, a Distributor can signal a system error.
This restricts distribution of SGIs to the first 16 PEs of an affinity 1 cluster.
If the IRM bit is 1, this field is RES0.

### Accessing the ICC_ASGI1R_EL1:

To access the ICC_ASGI1R_EL1:

MSR ICC_ASGI1R_EL1, <Xt> ; Write Xt to ICC_ASGI1R_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1011</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.7.4 **ICC_BPR0_EL1, Interrupt Controller Binary Point Register 0**

The ICC_BPR0_EL1 characteristics are:

**Purpose**

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field determines Group 0 interrupt preemption.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

The minimum binary point value is IMPLEMENTATION DEFINED, and is specified by ICC_CTLR_EL1.PRIbits and ICC_CTLR_EL3.PRIbits.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL0==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_BPR0_EL1 is architecturally mapped to AArch32 System register ICC_BPR0.

**Attributes**

ICC_BPR0_EL1 is a 32-bit register.

**Field descriptions**

The ICC_BPR0_EL1 bit assignments are:

```
31 3 2 0
RES0
```

Bits [31:3] Reserved, RES0.
BinaryPoint, bits [2:0]

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, that determines interrupt preemption, and a subpriority field. This is done as follows:

<table>
<thead>
<tr>
<th>Binary point value</th>
<th>Group priority field</th>
<th>Subpriority field</th>
<th>Field with binary point</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[7:1]</td>
<td>[0]</td>
<td>gggggg.s</td>
</tr>
<tr>
<td>1</td>
<td>[7:2]</td>
<td>[1:0]</td>
<td>gggggg.ss</td>
</tr>
<tr>
<td>2</td>
<td>[7:3]</td>
<td>[2:0]</td>
<td>gggggg.sss</td>
</tr>
<tr>
<td>3</td>
<td>[7:4]</td>
<td>[3:0]</td>
<td>gggggg.sss</td>
</tr>
<tr>
<td>4</td>
<td>[7:5]</td>
<td>[4:0]</td>
<td>gggg.sssss</td>
</tr>
<tr>
<td>5</td>
<td>[7:6]</td>
<td>[5:0]</td>
<td>gg.sssssss</td>
</tr>
<tr>
<td>6</td>
<td>[7]</td>
<td>[6:0]</td>
<td>g.sssssssss</td>
</tr>
<tr>
<td>7</td>
<td>No preemption</td>
<td>[7:0]</td>
<td>.ssssssssss</td>
</tr>
</tbody>
</table>

Accessing the ICC_BPR0_EL1:

To access the ICC_BPR0_EL1:

MRS <Xt>, ICC_BPR0_EL1 ; Read ICC_BPR0_EL1 into Xt
MSR ICC_BPR0_EL1, <Xt> ; Write Xt to ICC_BPR0_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.7.5 ICC_BPR1_EL1, Interrupt Controller Binary Point Register 1

The ICC_BPR1_EL1 characteristics are:

**Purpose**

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field determines Group 1 interrupt preemption.

**Usage constraints**

ICC_BPR1_EL1(S) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

ICC_BPR1_EL1(NS) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

The reset value is IMPLEMENTATION DEFINED, but is equal to:

- For the Secure copy of the register, the minimum value of ICC_BPR0_EL1.
- For the Non-secure copy of the register, the minimum value of ICC_BPR0_EL1 plus one.

An attempt to program the binary point field to a value less than the reset value sets the field to the reset value.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL1==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

There are separate Secure and Non-secure instances of this register.

AArch64 System register ICC_BPR1_EL1(S) is architecturally mapped to AArch32 System register ICC_BPR1 (S).

AArch64 System register ICC_BPR1_EL1(NS) is architecturally mapped to AArch32 System register ICC_BPR1 (NS).

In GIC implementations supporting two Security states, this register is Banked.

**Attributes**

ICC_BPR1_EL1 is a 32-bit register.

**Field descriptions**

The ICC_BPR1_EL1 bit assignments are:
Bits [31:3]

Reserved, RES0.

BinaryPoint, bits [2:0]

If the GIC is configured to use separate binary point fields for Group 0 and Group 1 interrupts, the value of this field controls how the 8-bit interrupt priority field is split into a group priority field, that determines interrupt preemption, and a subpriority field. This is done as follows:

<table>
<thead>
<tr>
<th>Binary point value</th>
<th>Group priority field</th>
<th>Subpriority field</th>
<th>Field with binary point</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>1</td>
<td>[7:1]</td>
<td>[0]</td>
<td>ggggggg.s</td>
</tr>
<tr>
<td>2</td>
<td>[7:2]</td>
<td>[1:0]</td>
<td>gggggg.ss</td>
</tr>
<tr>
<td>3</td>
<td>[7:3]</td>
<td>[2:0]</td>
<td>ggggg.sss</td>
</tr>
<tr>
<td>4</td>
<td>[7:4]</td>
<td>[3:0]</td>
<td>gggg.ssss</td>
</tr>
<tr>
<td>5</td>
<td>[7:5]</td>
<td>[4:0]</td>
<td>ggg.sssss</td>
</tr>
<tr>
<td>6</td>
<td>[7:6]</td>
<td>[5:0]</td>
<td>gg.sssssss</td>
</tr>
<tr>
<td>7</td>
<td>[7]</td>
<td>[6:0]</td>
<td>g.sssssssss</td>
</tr>
</tbody>
</table>

Writing 0 to this field will instead set this field to its reset value, which is IMPLEMENTATION DEFINED and non-zero.

If EL3 is implemented and ICC_CTLR_EL3.CBPR_EL1S is 1:

- Writing to this register at Secure EL1 modifies ICC_BPR0_EL1.
- Reading this register at Secure EL1 returns the value of ICC_BPR0_EL1.

If EL3 is implemented and ICC_CTLR_EL3.CBPR_EL1NS is 1, Non-secure accesses to this register at EL1 or EL2 behave as follows, depending on the values of HCR_EL2.IMO and SCR_EL3.IRQ:

<table>
<thead>
<tr>
<th>HCR_EL2.IMO</th>
<th>SCR_EL3.IRQ</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Non-secure EL1 and EL2 reads return ICC_BPR0_EL1 + 1 saturated to 0b111. Non-secure EL1 and EL2 writes are ignored.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Non-secure EL1 and EL2 accesses trap to EL3.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Non-secure EL1 accesses affect virtual interrupts. Non-secure EL2 reads return ICC_BPR0_EL1 + 1 saturated to 0b111. Non-secure EL2 writes are ignored.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Non-secure EL1 accesses affect virtual interrupts. Non-secure EL2 accesses trap to EL3.</td>
</tr>
</tbody>
</table>
If EL3 is not implemented and ICC_CTLR_EL1.CBPR is 1, Non-secure accesses to this register at EL1 or EL2 behave as follows, depending on the values of HCR_EL2.IMO:

<table>
<thead>
<tr>
<th>HCR_EL2.IMO</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Non-secure EL1 and EL2 reads return ICC_BPR0_EL1 + 1 saturated to 0b111. Non-secure EL1 and EL2 writes are ignored.</td>
</tr>
<tr>
<td>1</td>
<td>Non-secure EL1 accesses affect virtual interrupts. Non-secure EL2 reads return ICC_BPR0_EL1 + 1 saturated to 0b111. Non-secure EL2 writes are ignored.</td>
</tr>
</tbody>
</table>

**Accessing the ICC_BPR1_EL1:**

To access the ICC_BPR1_EL1:

MRS <Xt>, ICC_BPR1_EL1 ; Read ICC_BPR1_EL1 into Xt
MSR ICC_BPR1_EL1, <Xt> ; Write Xt to ICC_BPR1_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.7.6 ICC_CTLR_EL1, Interrupt Controller Control Register (EL1)

The ICC_CTLR_EL1 characteristics are:

**Purpose**

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

**Usage constraints**

ICC_CTLR_EL1(S) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

ICC_CTLR_EL1(NS) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

If ICH_HCR_EL2.TC==1, Non-secure EL1 accesses to this register are trapped to EL2.

If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.

If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.

If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

There are separate Secure and Non-secure instances of this register.

AArch64 System register ICC_CTLR_EL1(S) is architecturally mapped to AArch32 System register ICC_CTLR (S).

AArch64 System register ICC_CTLR_EL1(NS) is architecturally mapped to AArch32 System register ICC_CTLR (NS).

**Attributes**

ICC_CTLR_EL1 is a 32-bit register.

**Field descriptions**

The ICC_CTLR_EL1 bit assignments are:
Bits [31:16]
Reserved, RES0.

A3V, bit [15]
Affinity 3 Valid. Read-only and writes are ignored. Possible values are:
0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation System registers.
1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation System registers.

Virtual accesses return the value from ICH_VTR_EL2.A3V.
For physical accesses:
• If EL3 is implemented, physical accesses return the value from ICC_CTLR_EL3.A3V.
• If EL3 is not implemented, physical accesses return the value from this bit.

SEIS, bit [14]
SEI Support. Read-only and writes are ignored. Indicates whether the CPU interface supports local generation of SEIs:
0 The CPU interface logic does not support local generation of SEIs by the CPU interface.
1 The CPU interface logic supports local generation of SEIs by the CPU interface.

Virtual accesses return the value from ICH_VTR_EL2.SEIS.
For physical accesses:
• If EL3 is implemented, physical accesses return the value from ICC_CTLR_EL3.SEIS.
• If EL3 is not implemented, physical accesses return the value from this bit.

IDbits, bits [13:11]
Identifier bits. Read-only and writes are ignored. The number of physical interrupt identifier bits supported:
000 16 bits.
001 24 bits.
All other values are reserved.

Virtual accesses return the value from ICH_VTR_EL2.IDbits.
For physical accesses:
• If EL3 is implemented, physical accesses return the value from ICC_CTLR_EL3.IDbits.
• If EL3 is not implemented, physical accesses return the value from this field.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
PRIbits, bits [10:8]

Priority bits. Read-only and writes are ignored. The number of priority bits implemented, minus one.

An implementation that supports 2 Security states must implement at least 32 levels of physical priority (5 priority bits).
An implementation that supports only 1 Security state must implement at least 16 levels of physical priority (4 priority bits).

--- Note ---

This field always returns the number of bits implemented, regardless of the Security state of the access or the value of GICD_CTRLR.DS.

The division between group priority and subpriority is defined in the binary point registers ICC_BPR0_EL1 and ICC_BPR1_EL1.

Virtual accesses return the value from ICH_VTR_EL2.PRIbits.

For physical accesses:
- If EL3 is implemented, physical accesses return the value from ICC_CTRLR_EL3.PRIbits.
- If EL3 is not implemented, physical accesses return the value from this field.

Bit [7]

Reserved, RES0.

PMHE, bit [6]

Priority Mask Hint Enable. Controls whether the priority mask register is used as a hint for interrupt distribution:

- 0: Disables use of ICC_PMRE.L1 as a hint for interrupt distribution.
- 1: Enables use of ICC_PMRE.L1 as a hint for interrupt distribution.

Virtual accesses to this bit return RES0.

For physical accesses:
- If EL3 is implemented, this bit is an alias of ICC_CTRLR_EL3.PMHE. Whether this bit can be written as part of an access to this register depends on the value of GICD_CTRLR.DS:
  - If GICD_CTRLR.DS == 0, this bit is read-only.
  - If GICD_CTRLR.DS == 1, this bit is read/write.
- If EL3 is not implemented, it is IMPLEMENTATION DEFINED whether this bit is read-only or read-write:
  - If this bit is read-only, an implementation can choose to make this field RAZ/WI or RAO/WI.
  - If this bit is read/write, it resets to zero.

Bits [5:2]

Reserved, RES0.

EOImode, bit [1]

EOI mode for the current Security state. Controls whether a write to an End of Interrupt register also deactivates the interrupt:

- 0: ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide both priority drop and interrupt deactivation functionality. Accesses to ICC_DIR_EL1 are UNPREDICTABLE.
- 1: ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide priority drop functionality only. ICC_DIR_EL1 provides interrupt deactivation functionality.

Virtual accesses modify ICH_VMCR_EL2.VEOIM.
For physical accesses:

- If EL3 is implemented, this bit is an alias of ICC_CTLR_EL3.EOImode_EL1{S, NS} where S or NS corresponds to the current Security state.

- If EL3 is not implemented, it is IMPLEMENTATION DEFINED whether this bit is read-only or read-write:
  - If this bit is read-only, an implementation can choose to make this field RAZ/WI or RAO/WI.
  - If this bit is read/write, it resets to zero.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

**CBPR, bit [0]**

Common Binary Point Register. Controls whether the same register is used for interrupt preemption of both Group 0 and Group 1 interrupts:

0  ICC_BPR0_EL1 determines the preemption group for Group 0 interrupts only.
   ICC_BPR1_EL1 determines the preemption group for Group 1 interrupts.

1  ICC_BPR0_EL1 determines the preemption group for both Group 0 and Group 1 interrupts.

Virtual accesses modify ICH_VMCR_EL2.VCBPR.

For physical accesses:

- If EL3 is implemented:
  - This bit is an alias of ICC_CTLR_EL3.CBPR_EL1{S,NS} where S or NS corresponds to the current Security state.
  - If GICD_CTLR.DS == 0, this bit is read-only.
  - If GICD_CTLR.DS == 1, this bit is read/write.

- If EL3 is not implemented, it is IMPLEMENTATION DEFINED whether this bit is read-only or read-write:
  - If this bit is read-only, an implementation can choose to make this field RAZ/WI or RAO/WI.
  - If this bit is read/write, it resets to zero.

**Accessing the ICC_CTLR_EL1:**

To access the ICC_CTLR_EL1:

MRS <Xt>, ICC_CTLR_EL1 ; Read ICC_CTLR_EL1 into Xt
MSR ICC_CTLR_EL1, <Xt> ; Write Xt to ICC_CTLR_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>100</td>
</tr>
</tbody>
</table>
### ICC_CTLR_EL3, Interrupt Controller Control Register (EL3)

The ICC_CTLR_EL3 characteristics are:

**Purpose**

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th></th>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>RW</td>
<td>RW</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If ICC_SRE_EL3.SRE==0, EL3 accesses to this register are **UNDEFINED**.

**Configurations**

AArch64 System register ICC_CTLR_EL3 can be mapped to AArch32 System register ICC_MCTLR, but this is not architecturally mandated.

**Attributes**

ICC_CTLR_EL3 is a 32-bit register.

**Field descriptions**

The ICC_CTLR_EL3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>18-17</td>
<td>RES0</td>
</tr>
<tr>
<td>16</td>
<td>nDS</td>
</tr>
<tr>
<td>15</td>
<td>RES0</td>
</tr>
<tr>
<td>14</td>
<td>RES0</td>
</tr>
<tr>
<td>13</td>
<td>RES0</td>
</tr>
<tr>
<td>12</td>
<td>RES0</td>
</tr>
<tr>
<td>11-10</td>
<td>RES0</td>
</tr>
<tr>
<td>9</td>
<td>RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>RES0</td>
</tr>
<tr>
<td>6-5</td>
<td>RES0</td>
</tr>
<tr>
<td>4-3</td>
<td>RES0</td>
</tr>
<tr>
<td>2-1</td>
<td>RES0</td>
</tr>
<tr>
<td>0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:18]**

Reserved, RES0.

**nDS, bit [17]**

Disable Security not supported. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The CPU interface logic supports disabling of security.</td>
</tr>
<tr>
<td>1</td>
<td>The CPU interface logic does not support disabling of security, and requires that security is not disabled.</td>
</tr>
</tbody>
</table>
Bit [16]

Reserved, RES0.

A3V, bit [15]

Affinity 3 Valid. Read-only and writes are ignored. Possible values are:

0  The CPU interface logic does not support non-zero values of the Aff3 field in SGI generation System registers.
1  The CPU interface logic supports non-zero values of the Aff3 field in SGI generation System registers.

Virtual accesses return the value from ICH_VTR_EL2.A3V.

SEIS, bit [14]

SEI Support. Read-only and writes are ignored. Indicates whether the CPU interface supports generation of SEIs:

0  The CPU interface logic does not support generation of SEIs.
1  The CPU interface logic supports generation of SEIs.

Virtual accesses return the value from ICH_VTR_EL2.SEIS.

IDbits, bits [13:11]

Identifier bits. Read-only and writes are ignored. The number of physical interrupt identifier bits supported:

000  16 bits.
001  24 bits.
All other values are reserved.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

PRIbits, bits [10:8]

Priority bits. Read-only and writes are ignored. The number of priority bits implemented, minus one.

An implementation that supports 2 Security states must implement at least 32 levels of physical priority (5 priority bits).
An implementation that supports only 1 Security state must implement at least 16 levels of physical priority (4 priority bits).

Note

This field always returns the number of bits implemented, regardless of the value of SCR_EL3.NS or the value of GICD_CTLR.DS.

The division between group priority and subpriority is defined in the binary point registers ICC_BPR0_EL1 and ICC_BPR1_EL1.

Bit [7]

Reserved, RES0.

PMHE, bit [6]

Priority Mask Hint Enable.

0  Disables use of the priority mask register as a hint for interrupt distribution.
1  Enables use of the priority mask register as a hint for interrupt distribution.

Software must write ICC_PMR_EL1 to 0xFF before clearing this field to 0.

An implementation might choose to make this field RAO/WI.

When this register has an architecturally-defined reset value, this field resets to 0.
RM, bit [5]
Routing Modifier. For legacy operation of EL1 software with GICC_CTLR.FIQen set to 1, this bit indicates whether interrupts can be acknowledged or observed as the Highest Priority Pending Interrupt, or whether a special INTID value is returned.
Possible values of this bit are:
0  Secure Group 0 and Non-secure Group 1 interrupts can be acknowledged and observed as the highest priority interrupt at the Secure Exception level where the interrupt is taken.
1  When accessed at EL3 in AArch64 state:
   •  Secure Group 0 interrupts return a special INTID value of 1020. This affects accesses to ICC_IAR0_EL1 and ICC_HPPIR0_EL1.
   •  Non-secure Group 1 interrupts return a special INTID value of 1021. This affects accesses to ICC_IAR1_EL1 and ICC_HPPIR1_EL1.

--- Note ---
The Routing Modifier bit is supported in AArch64 only. In systems without EL3 the behavior is as if the value is 0.
Software must ensure this bit is 0 when the Secure copy of ICC_SRE_EL1.SRE is 1, otherwise system behavior is UNPREDICTABLE.

EOImode_EL1NS, bit [4]
EOI mode for interrupts handled at Non-secure EL1 and EL2. Controls whether a write to an End of Interrupt register also deactivates the interrupt:
0  ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide both priority drop and interrupt deactivation functionality. Accesses to ICC_DIR_EL1 are UNPREDICTABLE.
1  ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide priority drop functionality only. ICC_DIR_EL1 provides interrupt deactivation functionality.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

EOImode_EL1S, bit [3]
EOI mode for interrupts handled at Secure EL1. Controls whether a write to an End of Interrupt register also deactivates the interrupt:
0  ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide both priority drop and interrupt deactivation functionality. Accesses to ICC_DIR_EL1 are UNPREDICTABLE.
1  ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide priority drop functionality only. ICC_DIR_EL1 provides interrupt deactivation functionality.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

EOImode_EL3, bit [2]
EOI mode for interrupts handled at EL3. Controls whether a write to an End of Interrupt register also deactivates the interrupt:
0  ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide both priority drop and interrupt deactivation functionality. Accesses to ICC_DIR_EL1 are UNPREDICTABLE.
1  ICC_EOIR0_EL1 and ICC_EOIR1_EL1 provide priority drop functionality only. ICC_DIR_EL1 provides interrupt deactivation functionality.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.
CBPR_EL1NS, bit [1]

Common Binary Point Register, EL1 Non-secure. Controls whether the same register is used for interrupt preemption of both Group 0 and Group 1 Non-secure interrupts at EL1:

0  ICC_BPR0_EL1 determines the preemption group for Group 0 interrupts only.
  ICC_BPR1_EL1 determines the preemption group for Non-secure Group 1 interrupts.

1  ICC_BPR0_EL1 determines the preemption group for Group 0 interrupts and Non-secure Group 1 interrupts. Non-secure accesses to GICC_BPR and ICC_BPR1_EL1 access the state of ICC_BPR0_EL1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

CBPR_EL1S, bit [0]

Common Binary Point Register, EL1 Secure. Controls whether the same register is used for interrupt preemption of both Group 0 and Group 1 Secure interrupts at EL1:

0  ICC_BPR0_EL1 determines the preemption group for Group 0 interrupts only.
  ICC_BPR1_EL1 determines the preemption group for Secure Group 1 interrupts.

1  ICC_BPR0_EL1 determines the preemption group for Group 0 interrupts and Secure Group 1 interrupts. Secure accesses to ICC_BPR1_EL1 access the state of ICC_BPR0_EL1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the ICC_CTLR_EL3:

To access the ICC_CTLR_EL3:

MRS <Xt>, ICC_CTLR_EL3 ; Read ICC_CTLR_EL3 into Xt
MSR ICC_CTLR_EL3, <Xt> ; Write Xt to ICC_CTLR_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1100</td>
<td>1100</td>
<td>100</td>
</tr>
</tbody>
</table>
D7.7.8 ICC_DIR_EL1, Interrupt Controller Deactivate Interrupt Register

The ICC_DIR_EL1 characteristics are:

**Purpose**

When interrupt priority drop is separated from interrupt deactivation, a write to this register deactivates the specified interrupt.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICC_HCR_EL2.TC==1, Non-secure EL1 write accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 write accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_DIR_EL1 performs the same function as AArch32 System operation ICC_DIR.

**Attributes**

ICC_DIR_EL1 is a 32-bit register.

**Field descriptions**

The ICC_DIR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>23</td>
<td>INTID</td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**INTID, bits [23:0]**

The INTID of the interrupt to be deactivated.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_DIR_EL1:**

To access the ICC_DIR_EL1:

MSR ICC_DIR_EL1, <Xt> ; Write Xt to ICC_DIR_EL1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1011</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.7.9 ICC_EOIR0_EL1, Interrupt Controller End Of Interrupt Register 0

The ICC_EOIR0_EL1 characteristics are:

**Purpose**

A PE writes to this register to inform the CPU interface that it has completed the processing of the specified Group 0 interrupt.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid INTID, that is not a special interrupt ID.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL0==1, Non-secure EL1 write accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 write accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_EOIR0_EL1 performs the same function as AArch32 System operation ICC_EOIR0.

**Attributes**

ICC_EOIR0_EL1 is a 32-bit register.

**Field descriptions**

The ICC_EOIR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>INTID</td>
</tr>
</tbody>
</table>

**INTID, bits [23:0]**

The interrupt ID from the corresponding ICC_IAR0_EL1 access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

If the EOImode bit for the current Exception level and Security state is 0, a write to this register drops the priority for the interrupt, and also deactivates the interrupt.
If the EOImode bit for the current Exception level and Security state is 1, a write to this register only drops the priority for the interrupt. Software must write to ICC_DIR_EL1 to deactivate the interrupt.

The appropriate EOImode bit varies as follows:

- If EL3 is not implemented, the appropriate bit is ICC_CTLR_EL1.EOImode.
- If EL3 is implemented and the software is executing at EL3, the appropriate bit is ICC_CTLR_EL3.EOImode_EL3.
- If EL3 is implemented and the software is not executing at EL3, the bit depends on the current Security state:
  - If the software is executing in Secure state, the bit is ICC_CTLR_EL1.EOImode in the Secure instance of ICC_CTLR_EL1. This is an alias of ICC_CTLR_EL3.EOImode_EL1S.
  - If the software is executing in Non-secure state, the bit is ICC_CTLR_EL1.EOImode in the Non-secure instance of ICC_CTLR_EL1. This is an alias of ICC_CTLR_EL3.EOImode_EL1NS.

Accessing the ICC_EOIR0_EL1:

To access the ICC_EOIR0_EL1:

MSR ICC_EOIR0_EL1, <Xt> ; Write Xt to ICC_EOIR0_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>001</td>
</tr>
</tbody>
</table>

D7.7.10 ICC_EOIR1_EL1, Interrupt Controller End Of Interrupt Register 1

The ICC_EOIR1_EL1 characteristics are:

Purpose
A PE writes to this register to inform the CPU interface that it has completed the processing of the specified Group 1 interrupt.

Usage constraints
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid INTID, that is not a special interrupt ID.

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:
- If ICH_HCR_EL2.TALL1==1, Non-secure EL1 write accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 write accesses to this register are UNDEFINED.

Configurations
AArch64 System register ICC_EOIR1_EL1 performs the same function as AArch32 System operation ICC_EOIR1.

Attributes
ICC_EOIR1_EL1 is a 32-bit register.

Field descriptions
The ICC_EOIR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>INTID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:24]
Reserved, RES0.

INTID, bits [23:0]
The interrupt ID from the corresponding ICC_IAR1_EL1 access.
This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.
If the EOImode bit for the current Exception level and Security state is 0, a write to this register drops the priority for the interrupt, and also deactivates the interrupt.
If the EOImode bit for the current Exception level and Security state is 1, a write to this register only drops the priority for the interrupt. Software must write to ICC_DIR_EL1 to deactivate the interrupt.

The appropriate EOImode bit varies as follows:

- If EL3 is not implemented, the appropriate bit is ICC_CTLR_EL1.EOImode.
- If EL3 is implemented and the software is executing at EL3, the appropriate bit is ICC_CTLR_EL3.EOImode_EL3.
- If EL3 is implemented and the software is not executing at EL3, the bit depends on the current Security state:
  - If the software is executing in Secure state, the bit is ICC_CTLR_EL1.EOImode in the Secure instance of ICC_CTLR_EL1. This is an alias of ICC_CTLR_EL3.EOImode_EL1S.
  - If the software is executing in Non-secure state, the bit is ICC_CTLR_EL1.EOImode in the Non-secure instance of ICC_CTLR_EL1. This is an alias of ICC_CTLR_EL3.EOImode_EL1NS.

**Accessing the ICC_EOIR1_EL1:**

To access the ICC_EOIR1_EL1:

MSR ICC_EOIR1_EL1, <Xt> ; Write Xt to ICC_EOIR1_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>001</td>
</tr>
</tbody>
</table>
D7.7.11 ICC_HPPIR0_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 0

The ICC_HPPIR0_EL1 characteristics are:

**Purpose**

Indicates the highest priority pending Group 0 interrupt on the CPU interface.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If ICC_HCR_EL2.TALL==1, Non-secure EL1 read accesses to this register are trapped to EL2.

If ICC_SRE_EL1.SRE==0, EL1 read accesses to this register are UNDEFINED.

If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 read accesses to this register are UNDEFINED.

If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 read accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_HPPIR0_EL1 is architecturally mapped to AArch32 System register ICC_HPPIR0.

**Attributes**

ICC_HPPIR0_EL1 is a 32-bit register.

**Field descriptions**

The ICC_HPPIR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>INTID</td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**INTID, bits [23:0]**

The INTID of the highest priority pending interrupt, if that interrupt is observable at the current Security state and Exception level.

If the highest priority pending interrupt is not observable, this field contains a special INTID to indicate the reason. These special INTIDs are:

1020 When the register is read at EL3, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it must be handled at Secure EL1, either because it is a Secure Group 1 interrupt, or because it is a Secure Group 0 interrupt and ICC_CTRLR_EL3.RM == 1. The latter case applies to legacy operation only.

1021 When the register is read at EL3, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it is a Non-secure Group 1 interrupt that must be handled at Non-secure EL1 or EL2.
1023 Indicates that there is no pending interrupt, or the highest priority pending interrupt is not appropriate for the current Security state and Exception level, or not appropriate for this register.

An interrupt is not appropriate for this register if it is:

- A Group 1 interrupt, when this register is read while executing at an Exception level other than EL3.
- A Secure interrupt, when this register is read while executing in Non-secure state.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_HPPIR0_EL1:**

To access the ICC_HPPIR0_EL1:

MRS <Xt>, ICC_HPPIR0_EL1 ; Read ICC_HPPIR0_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.7.12 ICC_HPPIR1_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 1

The ICC_HPPIR1_EL1 characteristics are:

**Purpose**

Indicates the highest priority pending Group 1 interrupt on the CPU interface.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If ICC_HCR_EL2.TALL1==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 read accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_HPPIR1_EL1 is architecturally mapped to AArch32 System register ICC_HPPIR1.

**Attributes**

ICC_HPPIR1_EL1 is a 32-bit register.

**Field descriptions**

The ICC_HPPIR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**INTID, bits [23:0]**

The INTID of the highest priority pending interrupt, if that interrupt is observable at the current Security state and Exception level.

- If the highest priority pending interrupt is not observable, this field contains a special INTID to indicate the reason. These special INTIDs are:
  - 1020 When the register is read at EL3, and if ICC_CTLR_EL3.RM == 1, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it is a Secure Group 0 interrupt that must be handled at Secure EL1.
  - 1021 When the register is read at EL3, and if ICC_CTLR_EL3.RM == 1, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it is a Non-secure Group 1 interrupt that must be handled at Non-secure EL1 or EL2.
1023

Indicates that there is no pending interrupt, or the highest priority pending interrupt is not appropriate for the current Security state and Exception level, or not appropriate for this register.

An interrupt is not appropriate for this register if it is:

- A Group 0 interrupt, when this register is read while executing at EL3 and ICC_CTLR_EL3.RM == 0.
- A Group 0 interrupt, when this register is read while executing at an Exception level other than EL3.
- A Secure interrupt, when this register is read while executing in Non-secure state.
- A Non-secure Group 1 interrupt, when this register is read while executing at Secure EL1 if EL3 is using AArch64.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_HPPIR1_EL1:**

To access the ICC_HPPIR1_EL1:

```
MRS <Xt>, ICC_HPPIR1_EL1 ; Read ICC_HPPIR1_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>010</td>
</tr>
</tbody>
</table>
D7.7.13 ICC_IAR0_EL1, Interrupt Controller Interrupt Acknowledge Register 0

The ICC_IAR0_EL1 characteristics are:

Purpose

The PE reads this register to obtain the INTID of the signaled Group 0 interrupt. This read acts as an acknowledge for the interrupt.

Usage constraints

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL0==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 read accesses to this register are UNDEFINED.

Configurations

AArch64 System register ICC_IAR0_EL1 is architecturally mapped to AArch32 System register ICC_IAR0.

Attributes

ICC_IAR0_EL1 is a 32-bit register.

Field descriptions

The ICC_IAR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>INTID</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:24]

Reserved, RES0.

INTID, bits [23:0]

The INTID of the signaled interrupt.

This is the INTID of the highest priority pending interrupt, if that interrupt is of sufficient priority for it to be signaled to the PE, and if it can be acknowledged at the current Security state and Exception level.

If the highest priority pending interrupt cannot be acknowledged, this field contains a special INTID to indicate the reason. These special INTIDs are:

- When the register is read at EL3, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it must be handled at Secure EL1, either because it is a Secure Group 1 interrupt, or because it is a Secure Group 0 interrupt and ICC_CTLR_EL3.RM == 1. The latter case applies to legacy operation only.
When the register is read at EL3, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it is a Non-secure Group 1 interrupt that must be handled at Non-secure EL1 or EL2.

Indicates that there is no pending interrupt with sufficient priority to be signaled to the processor, or the highest priority pending interrupt is not appropriate for the current Security state and Exception level, or not appropriate for this register.

An interrupt is not appropriate for this register if it is:

• A Group 1 interrupt, when this register is read while executing at an Exception level other than EL3.
• A Secure interrupt, when this register is read while executing in Non-secure state.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_IAR0_EL1:**

To access the ICC_IAR0_EL1:

```
MRS <Xt>, ICC_IAR0_EL1  ; Read ICC_IAR0_EL1 into Xt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.7.14 ICC_IAR1_EL1, Interrupt Controller Interrupt Acknowledge Register 1

The ICC_IAR1_EL1 characteristics are:

**Purpose**

The PE reads this register to obtain the INTID of the signaled Group 1 interrupt. This read acts as an acknowledge for the interrupt.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization on page D1-1546. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL1==1, Non-secure EL1 read accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 read accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 read accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_IAR1_EL1 is architecturally mapped to AArch32 System register ICC_IAR1.

**Attributes**

ICC_IAR1_EL1 is a 32-bit register.

**Field descriptions**

The ICC_IAR1_EL1 bit assignments are:

```
 RES0  24  23  0
```

**Bits [31:24]**

Reserved, RES0.

**INTID, bits [23:0]**

The INTID of the signaled interrupt.

This is the INTID of the highest priority pending interrupt, if that interrupt is of sufficient priority for it to be signaled to the PE, and if it can be acknowledged at the current Security state and Exception level.

If the highest priority pending interrupt cannot be acknowledged, this field contains a special INTID to indicate the reason. These special INTIDs are:

- **1020**: When the register is read at EL3, and if ICC_CTLR_EL3.RM == 1, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it is a Secure Group 0 interrupt that must be handled at Secure EL1.
When the register is read at EL3, and if ICC_CTLR_EL3.RM == 1, indicates that the highest priority pending interrupt is of sufficient priority to be signaled, but it is a Non-secure Group 1 interrupt that must be handled at Non-secure EL1 or EL2.

Indicates that there is no pending interrupt with sufficient priority to be signaled to the processor, or the highest priority pending interrupt is not appropriate for the current Security state and Exception level, or not appropriate for this register.

An interrupt is not appropriate for this register if it is:

- A Group 0 interrupt, when this register is read while executing at EL3 and ICC_CTLR_EL3.RM == 0.
- A Group 0 interrupt, when this register is read while executing at an Exception level other than EL3.
- A Secure interrupt, when this register is read while executing in Non-secure state.
- A Non-secure Group 1 interrupt, when this register is read while executing at Secure EL1 if EL3 is using AArch64.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_IAR1_EL1:**

To access the ICC_IAR1_EL1:

MRS <Xt>, ICC_IAR1_EL1 ; Read ICC_IAR1_EL1 into Xt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.7.15 ICC_IGRPEN0_EL1, Interrupt Controller Interrupt Group 0 Enable register

The ICC_IGRPEN0_EL1 characteristics are:

**Purpose**

Controls whether Group 0 interrupts are enabled or not.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

The lowest Exception level at which this register can be accessed is governed by the Exception level to which FIQ is routed. This routing depends on SCR_EL3.FIQ, SCR_EL3.NS and HCR_EL2.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different PE.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL0==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_IGRPEN0_EL1 is architecturally mapped to AArch32 System register ICC_IGRPEN0.

**Attributes**

ICC_IGRPEN0_EL1 is a 32-bit register.

**Field descriptions**

The ICC_IGRPEN0_EL1 bit assignments are:

```
  31 1 0
  RES0 Enable
```

**Bits [31:1]**

Reserved, RES0.

**Enable, bit [0]**

Enables Group 0 interrupts.

- 0: Group 0 interrupts are disabled.
- 1: Group 0 interrupts are enabled.

Virtual accesses to this register update ICH_VMCR_EL2.VENG0.
When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the ICC_IGRPEN0_EL1:**

To access the ICC_IGRPEN0_EL1:

MRS <Xt>, ICC_IGRPEN0_EL1 ; Read ICC_IGRPEN0_EL1 into Xt
MSR ICC_IGRPEN0_EL1, <Xt> ; Write Xt to ICC_IGRPEN0_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>110</td>
</tr>
</tbody>
</table>
D7.7.16 ICC_IGRPEN1_EL1, Interrupt Controller Interrupt Group 1 Enable register

The ICC_IGRPEN1_EL1 characteristics are:

**Purpose**

Controls whether Group 1 interrupts are enabled for the current Security state.

**Usage constraints**

ICC_IGRPEN1_EL1(S) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

ICC_IGRPEN1_EL1(NS) is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

The lowest Exception level at which this register can be accessed is governed by the Exception level to which IRQ is routed. This routing depends on SCR_EL3.IRQ, SCR_EL3.NS and HCR_EL2.IMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different PE.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization on page D1-1546*. Subject to the prioritization rules:

- If ICH_HCR_EL2.TALL1==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

There are separate Secure and Non-secure instances of this register.

AArch64 System register ICC_IGRPEN1_EL1_EL1 is architecturally mapped to AArch32 System register ICC_IGRPEN1 (S).

AArch64 System register ICC_IGRPEN1_EL1_EL1 is architecturally mapped to AArch32 System register ICC_IGRPEN1 (NS).

**Attributes**

ICC_IGRPEN1_EL1 is a 32-bit register.

**Field descriptions**

The ICC_IGRPEN1_EL1 bit assignments are:
Bits [31:1]

Reserved, RES0.

Enable, bit [0]

Enables Group 1 interrupts for the current Security state.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Group 1 interrupts are disabled</td>
</tr>
<tr>
<td>1</td>
<td>Group 1 interrupts are enabled</td>
</tr>
</tbody>
</table>

Virtual accesses to this register update ICH_VMCR_EL2.VENG1.

If EL3 is present:
- This bit is a read/write alias of ICC_IGRPEN1_EL3.EnableGrp1{S, NS} as appropriate.
- When this register is accessed at EL3, the copy of this register appropriate to the current setting of SCR_EL3.NS is accessed.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the ICC_IGRPEN1_EL1:

To access the ICC_IGRPEN1_EL1:

MRS <Xt>, ICC_IGRPEN1_EL1 ; Read ICC_IGRPEN1_EL1 into Xt
MSR ICC_IGRPEN1_EL1, <Xt> ; Write Xt to ICC_IGRPEN1_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.7.17 ICC_IGRPEN1_EL3, Interrupt Controller Interrupt Group 1 Enable register (EL3)

The ICC_IGRPEN1_EL3 characteristics are:

**Purpose**

Controls whether Group 1 interrupts are enabled or not.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

If an interrupt is pending within the CPU interface when an Enable bit becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different PE.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

If ICC_SRE_EL3.SRE==0, EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_IGRPEN1_EL3 can be mapped to AArch32 System register ICC_MGRPEN1, but this is not architecturally mandated.

**Attributes**

ICC_IGRPEN1_EL3 is a 32-bit register.

**Field descriptions**

The ICC_IGRPEN1_EL3 bit assignments are:

```plaintext
   31  2  1  0
   +---+---+---+
   |   |   |   |
   +---+---+---+
  | RES0 | EnableGrp1S | EnableGrp1NS |
         +---+---+---+
```

**Bits [31:2]**

Reserved, RES0.

**EnableGrp1S, bit [1]**

Enables Group 1 interrupts for the Secure state.

|   | Secure Group 1 interrupts are disabled. |
| 0 | Secure Group 1 interrupts are enabled.  |

When this register has an architecturally-defined reset value, this field resets to 0.

**EnableGrp1NS, bit [0]**

Enables Group 1 interrupts for the Non-secure state.

|   | Non-secure Group 1 interrupts are disabled. |
| 0 | Non-secure Group 1 interrupts are enabled.  |
When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the ICC_IGRPEN1_EL3:**

To access the ICC_IGRPEN1_EL3:

MRS <Xt>, ICC_IGRPEN1_EL3 ; Read ICC_IGRPEN1_EL3 into Xt
MSR ICC_IGRPEN1_EL3, <Xt> ; Write Xt to ICC_IGRPEN1_EL3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>110</td>
<td>1100</td>
<td>1100</td>
<td>111</td>
</tr>
</tbody>
</table>
D7.7.18 ICC_PMR_EL1, Interrupt Controller Interrupt Priority Mask Register

The ICC_PMR_EL1 characteristics are:

**Purpose**

Provides an interrupt priority filter. Only interrupts with higher priority than the value in this register are signaled to the PE.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If ICH_HCR_EL2.TC==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_PMR_EL1 is architecturally mapped to AArch32 System register ICC_PMR.

**Attributes**

ICC_PMR_EL1 is a 32-bit register.

**Field descriptions**

The ICC_PMR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:8]</th>
<th>RES0</th>
<th>Priority</th>
</tr>
</thead>
</table>

Reserved, RES0.

**Priority, bits [7:0]**

The priority mask level for the CPU interface. If the priority of an interrupt is higher than the value indicated by this field, the interface signals the interrupt to the PE.

The possible priority field values are as follows:

<table>
<thead>
<tr>
<th>Implemented priority bits</th>
<th>Possible priority field values</th>
<th>Number of priority levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>[7:0]</td>
<td>0x00-0xFF (0-255), all values</td>
<td>256</td>
</tr>
<tr>
<td>[7:1]</td>
<td>0x00-0xFE (0-254), even values only</td>
<td>128</td>
</tr>
</tbody>
</table>
Unimplemented priority bits are RAZ/WI.
When this register has an architecturally-defined reset value, this field resets to 0.

### Accessing the ICC_PMR_EL1:

To access the ICC_PMR_EL1:

- `MRS <Xt>, ICC_PMR_EL1 ; Read ICC_PMR_EL1 into Xt`
- `MSR ICC_PMR_EL1, <Xt> ; Write Xt to ICC_PMR_EL1`

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>0100</td>
<td>0110</td>
<td>000</td>
</tr>
</tbody>
</table>
D7.7.19 ICC_RPR_EL1, Interrupt Controller Running Priority Register

The ICC_RPR_EL1 characteristics are:

**Purpose**

Indicates the Running priority of the CPU interface.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

If there are no active interrupts on the CPU interface, or all active interrupts have undergone priority drop, the value returned is the Idle priority.

Software cannot determine the number of implemented priority bits from a read of this register.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:

- If **ICH_HCR_EL2.TC==1**, Non-secure EL1 read accesses to this register are trapped to EL2.
- If **ICC_SRE_EL1.SRE==0**, EL1 read accesses to this register are UNDEFINED.
- If **ICC_SRE_EL2.SRE==0**, Non-secure EL1 and EL2 read accesses to this register are UNDEFINED.
- If **ICC_SRE_EL3.SRE==0**, EL1, EL2, and EL3 read accesses to this register are UNDEFINED.

**Configurations**

AArch64 System register ICC_RPR_EL1 is architecturally mapped to AArch32 System register ICC_RPR.

**Attributes**

ICC_RPR_EL1 is a 32-bit register.

**Field descriptions**

The ICC_RPR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**Priority, bits [7:0]**

The current running priority on the CPU interface. This is the group priority of the current active interrupt.

**Accessing the ICC_RPR_EL1:**

To access the ICC_RPR_EL1:

MRS <Xt>, ICC_RPR_EL1 ; Read ICC_RPR_EL1 into Xt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1011</td>
<td>011</td>
</tr>
</tbody>
</table>
D7.7.20 ICC_SGI0R_EL1, Interrupt Controller Software Generated Interrupt Group 0 Register

The ICC_SGI0R_EL1 characteristics are:

**Purpose**
Generates Secure Group 0 SGIs, including from the Non-secure state when permitted by GICR_NSACR.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization* on page D1-1546. Subject to the prioritization rules:
- If ICH_HCR_EL2.TC==1, Non-secure EL1 write accesses to this register are trapped to EL2.
- If ICC_SRE_EL1.SRE==0, EL1 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL2.SRE==0, Non-secure EL1 and EL2 write accesses to this register are UNDEFINED.
- If ICC_SRE_EL3.SRE==0, EL1, EL2, and EL3 write accesses to this register are UNDEFINED.

**Configurations**
AArch64 System register ICC_SGI0R_EL1 performs the same function as AArch32 System operation ICC_SGI0R.

**Attributes**
ICC_SGI0R_EL1 is a 64-bit register.

**Field descriptions**
The ICC_SGI0R_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Aff3</td>
</tr>
<tr>
<td>-----</td>
<td>-----</td>
</tr>
<tr>
<td>48</td>
<td>47</td>
</tr>
<tr>
<td>RES0</td>
<td>Aff2</td>
</tr>
<tr>
<td>-----</td>
<td>-----</td>
</tr>
<tr>
<td>32</td>
<td>31</td>
</tr>
<tr>
<td>RES0</td>
<td>INTID</td>
</tr>
<tr>
<td>-----</td>
<td>-----</td>
</tr>
<tr>
<td>24</td>
<td>23</td>
</tr>
<tr>
<td>Aff1</td>
<td>TargetList</td>
</tr>
<tr>
<td>-----</td>
<td>-----</td>
</tr>
<tr>
<td>16</td>
<td>15</td>
</tr>
<tr>
<td></td>
<td>IRM</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [63:56]**
Reserved, RES0.

**Aff3, bits [55:48]**
The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.
- If the IRM bit is 1, this field is RES0.

**Bits [47:41]**
Reserved, RES0.
IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to PEs. Possible values are:

0  Interrupts routed to the PEs specified by Aff3.Aff2.Aff1.<target list>.
1  Interrupts routed to all PEs in the system, excluding "self".

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated. If the IRM bit is 1, this field is RES0.

Bits [31:28]

Reserved, RES0.

INTID, bits [27:24]

The interrupt ID of the SGI.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated. If the IRM bit is 1, this field is RES0.

TargetList, bits [15:0]

Target List. The set of PEs for which SGI interrupts will be generated. Each bit corresponds to the PE within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target PE, the bit must be ignored by the Distributor. It is IMPLEMENTATION DEFINED whether, in such cases, a Distributor can signal a system error.

This restricts distribution of SGIs to the first 16 PEs of an affinity 1 cluster.

If the IRM bit is 1, this field is RES0.

Accessing the ICC_SGI0R_EL1:

To access the ICC_SGI0R_EL1:

MSR ICC_SGI0R_EL1, <Xt> ; Write Xt to ICC_SGI0R_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

1. Interrupts routed to all PEs in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.
If the IRM bit is 1, this field is RES0.

**Bits [31:28]**

Reserved, RES0.

**INTID, bits [27:24]**

The interrupt ID of the SGI.

**Aff1, bits [23:16]**

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.
If the IRM bit is 1, this field is RES0.

**TargetList, bits [15:0]**

Target List. The set of PEs for which SGI interrupts will be generated. Each bit corresponds to the PE within a cluster with an Affinity 0 value equal to the bit number.
If a bit is 1 and the bit does not correspond to a valid target PE, the bit must be ignored by the Distributor. It is IMPLEMENTATION DEFINED whether, in such cases, a Distributor can signal a system error.
This restricts distribution of SGIs to the first 16 PEs of an affinity 1 cluster.
If the IRM bit is 1, this field is RES0.

**Accessing the ICC_SGI1R_EL1:**

To access the ICC_SGI1R_EL1:

```
MSR ICC_SGI1R_EL1, <Xt> ; Write Xt to ICC_SGI1R_EL1
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1011</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.22 ICC_SRE_EL1, Interrupt Controller System Register Enable register (EL1)

The ICC_SRE_EL1 characteristics are:

**Purpose**

Controls whether the System register interface or the memory-mapped interface to the GIC CPU interface is used for EL0 and EL1.

**Usage constraints**

- ICC_SRE_EL1(S) is accessible as follows:
  - EL0 EL1 (NS) EL1 (S) EL2 (NS) EL3 (SCR.NS=1) EL3 (SCR.NS=0)
  - RW - - RW

- ICC_SRE_EL1(NS) is accessible as follows:
  - EL0 EL1 (NS) EL1 (S) EL2 (NS) EL3 (SCR.NS=1) EL3 (SCR.NS=0)
  - RW RW RW - -

The GIC architecture permits, but does not require, that registers can be shared between memory-mapped registers and the equivalent System registers. This means that if the memory-mapped registers have been accessed while ICC_SRE_EL1.SRE==0, then the System registers might be modified. Therefore, software must only rely on the reset values of the System registers if there has been no use of the GIC functionality while the memory-mapped registers are in use. Otherwise, the System register values must be treated as **UNKNOWN**.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization](#) on page D1-1546. Subject to the prioritization rules:

- If ICC_SRE_EL2.Enable==0, and ICC_SRE_EL2.SRE==1, Non-secure EL1 accesses to this register are trapped to EL2.
- If ICC_SRE_EL3.Enable==0, and ICC_SRE_EL3.SRE==1, EL1 and EL2 accesses to this register are trapped to EL3.

**Configurations**

There are separate Secure and Non-secure instances of this register.

- AArch64 System register ICC_SRE_EL1(S) is architecturally mapped to AArch32 System register ICC_SRE (S).
- AArch64 System register ICC_SRE_EL1(NS) is architecturally mapped to AArch32 System register ICC_SRE (NS).

**Attributes**

- ICC_SRE_EL1 is a 32-bit register.

**Field descriptions**

The ICC_SRE_EL1 bit assignments are:
Bits [31:3]
Reserved, RES0.

DIB, bit [2]
Disable IRQ bypass.
0 IRQ bypass enabled.
1 IRQ bypass disabled.
If EL3 is implemented and GICD_CTLR.DS == 0, this field is a read-only alias of ICC_SRE_EL3.DIB.
If EL3 is implemented and GICD_CTLR.DS == 1, and EL2 is not implemented, this field is a read-write alias of ICC_SRE_EL3.DIB.
If EL3 is not implemented or GICD_CTLR.DS == 1, and EL2 is implemented, this field is a read-only alias of ICC_SRE_EL2.DIB.
In systems that do not support IRQ bypass, this field is RAO/WI.
When this register has an architecturally-defined reset value, this field resets to 0.

DFB, bit [1]
Disable FIQ bypass.
0 FIQ bypass enabled.
1 FIQ bypass disabled.
If EL3 is implemented and GICD_CTLR.DS == 0, this field is a read-only alias of ICC_SRE_EL3.DFB.
If EL3 is implemented and GICD_CTLR.DS == 1, and EL2 is not implemented, this field is a read-write alias of ICC_SRE_EL3.DFB.
If EL3 is not implemented or GICD_CTLR.DS == 1, and EL2 is implemented, this field is a read-only alias of ICC_SRE_EL2.DFB.
In systems that do not support FIQ bypass, this field is RAO/WI.
When this register has an architecturally-defined reset value, this field resets to 0.

SRE, bit [0]
System Register Enable.
0 The memory-mapped interface must be used. Access at EL1 to any ICC_* System register other than ICC_SRE_EL1 results in an Undefined Instruction exception.
1 The System register interface for the current Security state is enabled.
Virtual accesses modify ICH_VMCR_EL2.VSRE.
If software changes this bit from 1 to 0 in the Secure instance of this register, the results are UNPREDICTABLE.
If an implementation supports only a System register interface to the GIC CPU interface, this bit is RAO/WI.
When this register has an architecturally-defined reset value, this field resets to 0.
Accessing the ICC_SRE_EL1:

To access the ICC_SRE_EL1:

MRS <Xt>, ICC_SRE_EL1 ; Read ICC_SRE_EL1 into Xt
MSR ICC_SRE_EL1, <Xt> ; Write Xt to ICC_SRE_EL1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>101</td>
</tr>
</tbody>
</table>
D7.7.23   ICC_SRE_EL2, Interrupt Controller System Register Enable register (EL2)

The ICC_SRE_EL2 characteristics are:

**Purpose**
Controls whether the System register interface or the memory-mapped interface to the GIC CPU interface is used for EL2.

**Usage constraints**
This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

The GIC architecture permits, but does not require, that registers can be shared between memory-mapped registers and the equivalent System registers. This means that if the memory-mapped registers have been accessed while ICC_SRE_EL2.SRE==0, then the System registers might be modified. Therefore, software must only rely on the reset values of the System registers if there has been no use of the GIC functionality while the memory-mapped registers are in use. Otherwise, the System register values must be treated as UNKNOWN.

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization on page D1-1546](#). Subject to the prioritization rules:

If ICC_SRE_EL3.Enable==0, and ICC_SRE_EL3.SRE==1, EL2 accesses to this register are trapped to EL3.

**Configurations**
AArch64 System register ICC_SRE_EL2 is architecturally mapped to AArch32 System register ICC_HSRE.

**Attributes**
ICC_SRE_EL2 is a 32-bit register.

**Field descriptions**
The ICC_SRE_EL2 bit assignments are:

```
   31  4  3  2  1  0
    |   |   |   |   |
    RES0

SRE  DFB  DIB  Enable
```

**Bits [31:4]**
Reserved, RES0.

**Enable, bit [3]**
Enable. Enables lower Exception level access to ICC_SRE_EL1.

0          Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL2.
Non-secure EL1 accesses to ICC_SRE_EL1 do not trap to EL2.
If ICC_SRE_EL2.SRE is RAO/WI, an implementation is permitted to make the Enable bit RAO/WI.
If ICC_SRE_EL2.SRE is 0, the Enable bit behaves as 1 for all purposes other than reading the value of the bit.
When this register has an architecturally-defined reset value, this field resets to 0.

**DIB, bit [2]**
Disable IRQ bypass.
0 IRQ bypass enabled.
1 IRQ bypass disabled.
If EL3 is implemented and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_SRE_EL3.DIB.
If EL3 is implemented and GICD_CTLR.DS is 1, this field is a read-write alias of ICC_SRE_EL3.DIB.
In systems that do not support IRQ bypass, this bit is RAO/WI.
When this register has an architecturally-defined reset value, this field resets to 0.

**DFB, bit [1]**
Disable FIQ bypass.
0 FIQ bypass enabled.
1 FIQ bypass disabled.
If EL3 is implemented and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_SRE_EL3.DFB.
If EL3 is implemented and GICD_CTLR.DS is 1, this field is a read-write alias of ICC_SRE_EL3.DFB.
In systems that do not support FIQ bypass, this bit is RAO/WI.
When this register has an architecturally-defined reset value, this field resets to 0.

**SRE, bit [0]**
System Register Enable.
0 The memory-mapped interface must be used. Access at EL2 or below to any ICH_* System register, or any EL1 or EL2 ICC_* register other than ICC_SRE_EL1 or ICC_SRE_EL2, results in an Undefined Instruction exception.
1 The System register interface to the ICH_* registers and the EL1 and EL2 ICC_* registers is enabled for EL2.
If software changes this bit from 1 to 0, the results are UNPREDICTABLE.
If an implementation supports only a System register interface to the GIC CPU interface, this bit is RAO/WI.
When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the ICC_SRE_EL2:**
To access the ICC_SRE_EL2:

MRS <Xt>, ICC_SRE_EL2 ; Read ICC_SRE_EL2 into Xt
MSR ICC_SRE_EL2, <Xt> ; Write Xt to ICC_SRE_EL2
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>100</td>
<td>1100</td>
<td>1001</td>
<td>101</td>
</tr>
</tbody>
</table>
### D7.7.24 ICC_SRE_EL3, Interrupt Controller System Register Enable register (EL3)

The ICC_SRE_EL3 characteristics are:

**Purpose**

Controls whether the System register interface or the memory-mapped interface to the GIC CPU interface is used for EL3.

**Usage constraints**

This register is accessible as follows:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2 (NS)</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is always System register accessible.

The GIC architecture permits, but does not require, that registers can be shared between memory-mapped registers and the equivalent System registers. This means that if the memory-mapped registers have been accessed while ICC_SRE_EL3.SRE==0, then the System registers might be modified. Therefore, software must only rely on the reset values of the System registers if there has been no use of the GIC functionality while the memory-mapped registers are in use. Otherwise, the System register values must be treated as UNKNOWN.

**Traps and Enables**

There are no traps or enables affecting this register.

**Configurations**

AArch64 System register ICC_SRE_EL3 can be mapped to AArch32 System register ICC_MSRE, but this is not architecturally mandated.

**Attributes**

ICC_SRE_EL3 is a 32-bit register.

**Field descriptions**

The ICC_SRE_EL3 bit assignments are:

```
  31          RES0
    4  3  2  1  0
  
SRE  DFB  DIB  Enable

Bits [31:4] Reserved, RES0.
Enable, bit [3]

   Enable. Enables lower Exception level access to ICC_SRE_EL1 and ICC_SRE_EL2.
